ORGANIZING INSTITUTIONS

CONGRESS ID

CONGRESS TITLE

5TH SIVAS INTERNATIONAL CONGRESS OF SCIENTIFIC RESEARCH AND INNOVATION

DATE AND PLACE

25–27 September 2026 · Sivas University of Science and Technology, Sivas, Türkiye

CONGRESS STATISTICS

TOTAL ACCEPTED PAPERS	TOTAL REJECTED PAPERS	TOTAL PAPERS FROM TÜRKIYE	TOTAL PAPERS FROM INTERNATIONAL PARTICIPANTS
250	**59**	**123**	**127**

PARTICIPANT COUNTRIES (34)

Türkiye, India, Nigeria, Afghanistan, Algeria, Pakistan, Iran, Tunisia, Morocco, Indonesia, Romania, Lebanon, Libya, Republic of Moldova, Ukraine, Italy, Vietnam, Kosovo, Uganda, Niger Republic, Mexico, Azerbaijan, Albania, Republic of Guinea, North Macedonia, USA, Tanzania, Oman, Kyrgyzstan, TRNC, Bulgaria, Russia, Malaysia, Iraq

EVALUATION PROCESS

› All applications have undergone a double-blind peer review process

PRESENTATION

› Oral Presentations

HONORARY PRESIDENT OF CONFERENCE

Prof. Dr. Mehmet KUL
Rector of Sivas University of Science and Technology

HEAD OF CONFERENCE

Prof. Dr. Kağan KÖKTEN
Vice Rector of Sivas University of Science and Technology

ORGANIZING COMMITTEE MEMBERS

Prof. Dr. Kağan KÖKTEN *Sivas University of Science and Technology/Türkiye*	**Prof. Dr. Sabit HOROZ** *Sivas University of Science and Technology/Türkiye*
Prof. Dr. Muhammad ASIM *Sivas University of Science and Technology/Türkiye*	**Prof. Dr. Ender KESKİNKILIÇ** *Sivas University of Science and Technology/Türkiye*
Prof. Dr. Metin ZONTUL *Sivas University of Science and Technology/Türkiye*	**Prof. Dr. Tolga KARAKÖY** *Sivas University of Science and Technology/Türkiye*
Prof. Dr. Ömer SÖZEN *Sivas University of Science and Technology/Türkiye*	**Prof. Dr. Sezai ERCİŞLİ** *Atatürk University/Türkiye*
Prof. Dr. Fatih DADAŞOĞLU *Atatürk University/Türkiye*	**Prof. Dr. Neslihan DİKBAŞ** *Atatürk University/Türkiye*
Prof. Dr. Mahmut KAPLAN *Erciyes University/Türkiye*	**Prof. Dr. Faheem Shahzad BALOCH** *Mersin University/Türkiye*
Prof. Dr. Özlem BARIŞ *Kyrgyz-Turkish Manas University/Kyrgyz Republic*	**Prof. Dr. Meisam ZARGAR** *RUDN University/Russia*
Prof. Dr. Yaşar KARADAĞ *Necmettin Erbakan University/Türkiye*	**Assoc. Prof. Dr. Tamraz TAMRAZOV** *Research Institute of Crop Husbandry/Azerbaijan*
Assoc. Prof. Dr. Selma HOUCHI *University Ferhat Abbas of Setif/Algeria*	**Assoc. Prof. Dr. Nazım BABACAN** *Sivas University of Science and Technology/Türkiye*
Assoc. Prof. Dr. Fuat ERDEN *Sivas University of Science and Technology/Türkiye*	**Assoc. Prof. Dr. Emre EVLİCE** *Sivas University of Science and Technology/Türkiye*
Assoc. Prof. Dr. Gökhan BAKTEMUR *Sivas University of Science and Technology/Türkiye*	**Assoc. Prof. Dr. Fikret SAYGIN** *Sivas University of Science and Technology/Türkiye*
Assoc. Prof. Dr. Zemran MUSTAFA *Sivas University of Science and Technology/Türkiye*	**Assoc. Prof. Dr. Asuman KAPLAN EVLİCE** *Sivas University of Science and Technology/Türkiye*
Assoc. Prof. Dr. Yeter ÇİLESİZ *Sivas University of Science and Technology/Türkiye*	**Assoc. Prof. Dr. Fatih ÖLMEZ** *Sivas University of Science and Technology/Türkiye*
Assoc. Prof. Dr. Hale GÜNAÇTI *Sivas University of Science and Technology/Türkiye*	**Assoc. Prof. Dr. Mustafa AKBABA** *Sivas University of Science and Technology/Türkiye*
Assoc. Prof. Dr. Pervin ERDOĞAN *Sivas University of Science and Technology/Türkiye*	**Assist. Prof. Dr. Amjad ALİ** *Sivas University of Science and Technology/Türkiye*
Assist. Prof. Dr. Göksu TAŞ *Sivas University of Science and Technology/Türkiye*	**Assist. Prof. Dr. Sedat SEVEROĞLU** *Atatürk University/Türkiye*
Assist. Prof. Dr. Selim ÖZDEMİR *Bingöl University/Türkiye*	**Assist. Prof. Dr. Rıdvan UÇAR** *Pamukkale University/Türkiye*
Dr. Muhammed TATAR *Sivas University of Science and Technology/Türkiye*	**Dr. İlhan DANACI** *Sivas University of Science and Technology/Türkiye*
Dr. Sajid FIAZ *The University of Lahore/Pakistan*	**Dr. Farhat ABBAS** *Sichuan Agricultural University/China*
Khalid Ali KHAN *King Khalid University Abha/Saudi Arabia*	**Dr. Fawad ALI** *School of Tropical Agriculture and Forestry Hainan University/China*
Dr. Tajamul HUSSAIN *Oregon State University/United States*	**Dr. Muhammad Farhan YOUSAF** *Center for Quantitative Genetics and Genomics Aarhus University/Denmark*

INTERNATIONAL SCIENTIFIC COMMITTEE

Prof. Dr. Burhan KARA *Isparta University of Applied Sciences/Türkiye*	**Prof. Dr. Cengiz TOKER** *Akdeniz University/Türkiye*
Prof. Dr. Disna RATNASEKERA *University of Ruhuna/Sri Lanka*	**Prof. Dr. Durdane YANAR** *Tokat Gaziosmanpaşa University/Türkiye*
Prof. Dr. Ercan CEYHAN *Selçuk University/Türkiye*	**Prof. Dr. Hatıra TAŞKIN** *Çukurova University/Türkiye*
Prof. Dr. Hirofumi SANEOKA *Hiroshima University/Japan*	**Prof. Dr. İlhami BAYRAMİN** *Ankara University/Türkiye*
Prof. Dr. İlknur SOLMAZ *Çukurova University/Türkiye*	**Prof. Dr. Kağan KÖKTEN** *Sivas University of Science and Technology/Türkiye*
Prof. Dr. M. Shohidul ISLAM *Hajee Mohammad Danesh Science and Technology University/Bangladesh*	**Prof. Dr. Marian BRESTIC** *Slovak University of Agriculture/Slovakia*
Prof. Dr. Mehmet Ali AVCI *Selcuk University/Türkiye*	**Prof. Dr. Metin ZONTUL** *Sivas University of Science and Technology/Türkiye*
Prof. Dr. Muhammad ASIM *Sivas University of Science and Technology/Türkiye*	**Prof. Dr. Mustafa KIZILSIMSEK** *Kahramanmaras Sutcu Imam University/Türkiye*
Prof. Dr. Mustafa SURMEN *Aydin Adnan Menderes University/Türkiye*	**Prof. Dr. Oğuz BAŞKAN** *Siirt University/Türkiye*
Prof. Dr. Oksana SYTAR *Taras Shevchenko National University of Kyiv/Ukraine*	**Prof. Dr. Ömer SÖZEN** *Sivas University of Science and Technology/Türkiye*

Dr. Muhammad Abu BAKAR ZIA *University of Layyah/Pakistan*	**Research Assist. Dr. Ecem KARA** *Sivas University of Science and Technology/Türkiye*
Research Assist. Dr. İlker YÜCE *Sivas University of Science and Technology /Türkiye*	**Research Assist. Dr. Muhammed TATAR** *Sivas University of Science and Technology/Türkiye*
Research Assist. Dr. Sevda UÇAR *Sivas University of Science and Technology/Türkiye*	**Research Assist. Dr. Mehmet BEDİR** *Sivas University of Science and Technology /Türkiye*
Research Assist. Dr. İlhan DANACI *Sivas University of Science and Technology/Türkiye*	**Research Assist. Dr. Meliha Feryal SARIKAYA** *Sivas University of Science and Technology/Türkiye*
Research Assist. Furkan ULAŞ *Sivas University of Science and Technology/Türkiye*	**Research Assist. Zeynep YUMLU** *Sivas University of Science and Technology/Türkiye*
Research Assist. Melike KAYA *Sivas University of Science and Technology/Türkiye*	**Research Assist. Erturan YETİŞKİN** *Sivas University of Science and Technology/Türkiye*
Research Assist. Başar Deniz GIRGIN *Sivas University of Science and Technology/Türkiye*	**Research Assist. Erhan YOLDAŞ** *Sivas University of Science and Technology/Türkiye*
Research Assist. Deniz AKTÜRK *Sivas University of Science and Technology/Türkiye*	**Research Assist. Merve GENÇTÜRK** *Sivas University of Science and Technology/Türkiye*

5th Sivas International Congress of Scientific Research and Innovation

25–27 September 2026 · Sivas University of Science and Technology

Congress Program

MEETING ID	PASSCODE	ZOOM LINK
862 1528 3413	**123456**	**https://us02web.zoom.us/j/86215283413?pwd=yYsMZ4OzNwxojkqaSYcs6xXw3Rua9a.1**

PARTICIPANT COUNTRIES (34)

Türkiye, India, Nigeria, Afghanistan, Algeria, Pakistan, Iran, Tunisia, Morocco, Indonesia, Romania, Lebanon, Libya, Republic of Moldova, Ukraine, Italy, Vietnam, Kosovo, Uganda, Niger Republic, Mexico, Azerbaijan, Albania, Republic of Guinea, North Macedonia, USA, Tanzania, Oman, Kyrgyzstan, TRNC, Bulgaria, Russia, Malaysia, Iraq

IMPORTANT — PLEASE READ CAREFULLY

- To attend online: go to zoom.us/join, enter Meeting ID and join.
- Zoom is free and no account is required. Works on tablets, phones and PCs.
- Connect 5 minutes before your presentation time.
- All participants can listen to all sessions live.
- The moderator is responsible for presentations and Q&A.

TECHNICAL INFORMATION

- Make sure your computer microphone is working.
- Enable the screen sharing feature in Zoom.
- Attendance certificates will be sent as PDF after congress.
- Requests for change of place or time will not be considered

OPENING CEREMONY

25.09.2026 / Sivas University of Science and Technology
Ankara Time: 09:30-10:30

***

Prof. Dr. Kağan KÖKTEN
Vice Rector of Sivas University of Science and Technology
HEAD OF THE CONFERENCE

***

Prof. Dr. Mehmet KUL
Rector of Sivas University of Science and Technology
HONORARY PRESIDENT OF THE CONFERENCE

***

Prof. Dr. Muhammad ASIM
Sivas University of Science and Technology, Türkiye

IN PERSON SESSIONS

DATE: 25.09.2026

IN PERSON
Hall-1

SESSION · HALL
In Person · Session-1 · Hall-1

DATE
25 September 2026

VENUE
Sivas University of Science and Technology

TIME 10:30-12:30

HEAD OF SESSION: Asst. Prof. Celal ALAGÖZ

AUTHOR(S)	ORGANISATION	TOPIC TITLE
Fahrettin Burak İLDEN Celal ALAGÖZ Mehmet KURNAZ	*Sivas University of Science and Technology, Türkiye*	**ESTIMATION OF BODY MASS INDEX FROM 12-LEAD ECG SIGNALS USING MINIROCKET FEATURES AND BAGGED ENSEMBLE NEURAL NETWORKS**
Mehmet KURNAZ Asst. Prof. Celal ALAGÖZ Tuna Sencer FİGANKAPLAN	*Sivas University of Science and Technology, Türkiye*	**FAST-TCN-FUSION: A MULTI-SCALE TCN AND FFT-BASED ADAPTIVE TIME–FREQUENCY FUSION ARCHITECTURE FOR TIME SERIES CLASSIFICATION**
Assoc. Prof. Dr. Emre BÜLBÜL Assoc. Prof. Dr. Mehmet DOĞAN	*Erciyes University, Türkiye*	**THE IMPORTANCE AND USE OF ADRENALINE AUTO-INJECTORS IN ANAPHYLAXIS**
Assoc. Prof. Dr. Mehmet DOĞAN Assoc. Prof. Dr. Emre BÜLBÜL	*Erciyes University, Türkiye*	**EVALUATION OF THE SUICIDE CASES OF THE LAST 10 YEARS IN TÜRKİYE**
Asst. Prof. Dr. Yunus ÇELİK Asst. Prof. Dr. Onur ERKAN	*Sivas University of Science and Technology, Türkiye* *Bilecik Şeyh Edebali University, Türkiye*	**PERFORMANCE EVALUATION OF A 2D LBM SOLVER FOR FLOW AROUND CYLINDERS ACROSS VARIOUS ASPECT RATIOS**
Asst. Prof. Dr. Onur ERKAN	*Bilecik Şeyh Edebali University, Türkiye*	**A NUMERICAL ASSESSMENT OF AN INCLINED FLAT PLATE WITH A SEMICIRCULAR CYLINDER FOR FLOW-INDUCED ENERGY HARVESTING**
Asst. Prof. Dr. Aydın GÜNEŞ	*Abdullah Gül University, Türkiye*	**INVESTIGATION OF PRODUCING COMPOSITE MATERIALS FROM WASTE ALUMINUM AND CUSN10 BRONZE CHIPS BY HOT EXTRUSION**
Tacettin ERGENÇ	*Independent Researcher, Türkiye*	**CONTEXT-AWARE MACHINE LEARNING FOR ANOMALY DETECTION IN NANOINDENTATION CURVES: SAMPLE-GROUPED VALIDATION**
Kübra AYHAN TANYILDIZ Ferhat DELİBAŞ Göksel ARAS Assoc. Prof. Dr. Ebru YABAŞ	*Sivas Cumhuriyet University, Türkiye*	**DESIGN AND DEVELOPMENT OF NEXT-GENERATION MODULAR STORAGE SYSTEMS**
Ömer KOÇOĞLU Ferhat DELİBAŞ Göksel ARAS Assoc. Prof. Dr. Ebru YABAŞ	*Sivas Cumhuriyet University, Türkiye*	**FROM CORRECT POSITIONING TO STANDARDIZED PRODUCTS IN ROBOTIC WELDING: THE ROLE OF WELDING FIXTURES IN THE PRODUCTION PROCESS**

IN PERSON

Sivas University of Science and Technology

DATE
25 September 2026

TIME: 10:30-12:30

HEAD OF SESSION: Prof. Dr. Sabit HOROZ

AUTHOR(S)	ORGANISATION	TOPIC TITLE
Res. Asst. Aslıhan ANTER ALTAN Prof. Dr. Elif ORHAN	*Gazi University, Türkiye*	**EFFECT OF INCIDENT OPTICAL POWER DENSITY ON THE PHOTORESPONSE OF A DOPED GRAPHENE QUANTUM DOT-BASED HETEROJUNCTION**
Dr. Zeynep BERKTAŞ Prof. Dr. Elif ORHAN	*Gazi University, Türkiye*	**PHOTODETECTION PERFORMANCE OF A BISMUTH-DOPED GRAPHENE QUANTUM DOT-BASED HETEROJUNCTION AFTER 24 MONTHS**
Res. Asst. Melis Irmak AYDIN Prof. Dr. Ayşe BAYRAKÇEKEN	*Atatürk University, Türkiye*	**HETEROATOM DOPING OF PEM FUEL CELL ELECTROCATALYST MATERIALS**
Asst. Prof. Dr. Yılmaz MERT Asst. Prof. Dr. İbrahim KORKUT	*Sivas University of Science and Technology, Türkiye*	**SYNTHESIS OF HCL-DOPED POLYANILINE BY CHEMICAL OXIDATIVE POLYMERISATION AND ITS ADSORPTIVE PERFORMANCE FOR METHYLENE BLUE**
Emre BİÇER Tülay AKSOY	*Ankara University, Türkiye* *Sivas University of Science and Technology, Türkiye*	**OXIDE-BASED SOLID ELECTROLYTES FOR SOLID-STATE LITHIUM BATTERIES: ION TRANSPORT, MATERIAL CLASSES, AND PROCESSING STRATEGIES**
Assoc. Prof. Dr. Salih ÖZBAY	*Sivas University of Science and Technology, Türkiye*	**THERMODYNAMIC PREDICTION OF POLYPROPYLENE–SOLVENT/NONSOLVENT INTERACTIONS USING HANSEN SOLUBILITY PARAMETERS AND FLORY–HUGGINS THEORY**
İpek BALNAN Prof. Dr. Sabit HOROZ	*Sivas University of Science and Technology, Türkiye* *Sivas University of Science and Technology; Sivas Cumhuriyet University, Türkiye*	**CDS SEMICONDUCTOR IN PHOTOCATALYTIC APPLICATIONS: A MINI REVIEW**
İpek BALNAN Prof. Dr. Sabit HOROZ	*Sivas University of Science and Technology, Türkiye* *Sivas University of Science and Technology; Sivas Cumhuriyet University, Türkiye*	**STRUCTURAL AND OPTICAL CHARACTERIZATION OF CU-DOPED ZNS NANOPARTICLES SYNTHESIZED BY SOL-GEL METHOD AT DIFFERENT ANNEALING TEMPERATURES**

Mitigation Strategies
Technological: biodegradable/bio-based plastics, improved sorting and recycling, capture devices and AI-enabled monitoring.
Governance: international agreements, national legislation, extended producer responsibility instruments.
Community action: awareness campaigns, waste segregation, clean-up programmes and infor engagement.
Local innovation: converting recovered plastic into construction materials.
Circular-economy approaches can reduce plastic inputs and improve resource recovery.

Assia Allaoui-Naamoune
Samuel Maida Dogo
BACKGROUND
Why milk quality perception matters
1
A staple food
Milk is a central product in Algerian diets, valued for its nutritional role and daily presence in households.
2
Two competing formats
Consumers routinely choose between UHT (long-life, cartoned) milk and sachet (pasteurized, bagged) milk.
3
Quality is subjective
Beyond composition, perceived quality is shaped by taste, smell, texture, appearance, packaging and trust.
4
An industry gap
Little is known about how Algerian consumers actually perceive and evaluate the milk they buy.
Sensory Evaluation of Milk Quality — Algerian Consumers

ABSTRACT
Accurate estimation of body mass index (BMI) categories from routinely acquired physiological signals may provide a practical alternative when direct anthropometric measurements are unavailable or difficult to obtain. However, inferring BMI from electrocardiogram (ECG) recordings is challenging because the relationship between body composition and cardiac electrical activity is indirect and affected by substantial inter-individual variability, cardiac conditions, and signal noise. In this study, we propose an efficient ensemble machine learning framework for three-class BMI classification into Underweight, Normal, and Overweight/Obese categories using 6,586 12-lead ECG recordings from the PTB-XL dataset. The ECG signals were sampled at 100 Hz, bandpass-filtered between 0.5 and 40 Hz, and independently normalized across channels. Two complementary time-series feature-extraction methods were employed to transform the multivariate ECG signals into a high-dimensional feature representation capable of capturing discriminative temporal and morphological patterns: MiniRocket, using 10,000 convolutional kernels, and QUANT, a minimalist interval-based transform that computes quantile features over dyadic intervals of the signal. To reduce redundancy and computational complexity, the combined feature set was standardized and projected onto 300 principal components using Principal Component Analysis (PCA), after which demographic information, including age and sex, was incorporated. The resulting feature representation was classified using a nine-model bagged Multi-Layer Perceptron (MLP) ensemble comprising three complementary hidden-layer configurations and three independent random initializations per configuration. Model performance was assessed using stratified five-fold cross-validation. The proposed ensemble achieved fold-level accuracies ranging from 62.79% to 65.17%, with a mean accuracy of 63.83% ± 0.77% and a mean balanced accuracy of 45.84% ± 0.93%. The lower balanced accuracy reflects the substantial class imbalance, with Underweight cases accounting for only 4.2% of the cohort. For the clinically more prevalent Normal and Overweight/Obese categories, the model achieved an isolated classification accuracy of 66.44%. Overall, the findings indicate that ECG-derived temporal morphology, particularly when combined with demographic information, contains measurable information related to BMI category and can support non-invasive opportunistic biometric estimation, while also demonstrating the need for improved strategies for minority-class prediction.
Keywords: Body Mass Index, MiniRocket, QUANT, Bagged Ensemble MLP, Biometric Estimation.

ÖZET
Rutin olarak elde edilen fizyolojik sinyallerden vücut kitle indeksi (VKİ) kategorilerinin doğru şekilde tahmin edilmesi, doğrudan antropometrik ölçümlerin bulunmadığı veya elde edilmesinin zor olduğu durumlarda pratik bir alternatif sunabilir. Ancak vücut bileşimi ile kardiyak elektriksel aktivite arasındaki ilişkinin dolaylı olması, bireyler arası yüksek varyasyondan, kardiyak durumlardan ve sinyal gürültüsünden etkilenmesi nedeniyle elektrokardiyogram (EKG) kayıtlarından VKİ tahmini yapmak oldukça güçtür. Bu çalışmada, PTB-XL veri setinden alınan 6.586 adet 12 derivasyonlu EKG kaydı kullanılarak VKİ'nin Zayıf, Normal ve Fazla Kilolu/Obez şeklinde üç sınıfta sınıflandırıldığı verimli bir topluluk (ensemble) makine öğrenmesi mimarisi önerilmektedir. EKG sinyalleri 100 Hz frekansta

örneklenmiş, 0,5-40 Hz arasında bant geçiren filtreden geçirilmiş ve kanallar arasında bağımsız olarak normalize edilmiştir. Ayrıştırıcı zamansal ve morfolojik örüntüleri yakalayabilen yüksek boyutlu bir öznitelik temsiline çok değişkenli EKG sinyallerini dönüştürmek amacıyla, biri 10.000 konvolüsyon çekirdeği kullanan MiniRocket, diğeri sinyalin diyadik aralıklarından kantil öznitelikleri hesaplayan minimalist bir aralık tabanlı yöntem olan QUANT olmak üzere iki tamamlayıcı zaman serisi öznitelik çıkarım yöntemi uygulanmıştır. Gereksiz verileri ve hesaplama karmaşıklığını azaltmak için çıkarılan öznitelikler standartlaştırılmış ve Temel Bileşen Analizi (PCA) kullanılarak 300 temel bileşene indirgenmiş, ardından yaş ve cinsiyet gibi demografik bilgiler sürece dahil edilmiştir. Elde edilen öznitelik temsili; üç tamamlayıcı gizli katman konfigürasyonu ve konfigürasyon başına üç bağımsız rastgele başlatma içeren, dokuz modelli bir torbalanmış (bagged) Çok Katmanlı Algılayıcı (MLP) topluluğu ile sınıflandırılmıştır. Model performansı, katmanlı 5 katlı çapraz doğrulama (stratified 5-fold cross-validation) ile değerlendirilmiştir. Önerilen topluluk modeli %62,79 ile %65,17 arasında değişen katman düzeyinde doğruluk değerleri elde etmiş; ortalama doğruluk %63,83 ± %0,77 ve ortalama dengeli doğruluk ise %45,84 ± %0,93 olarak gerçekleşmiştir. Düşük dengeli doğruluk oranı, Zayıf vakaların kohortun yalnızca %4,2'sini oluşturduğu belirgin sınıf dengesizliğini yansıtmaktadır. Klinik açıdan daha yaygın olan Normal ve Fazla Kilolu/Obez kategorileri için model, %66,44'lük izole bir sınıflandırma doğruluğuna ulaşmıştır. Genel olarak bulgular, EKG kaynaklı zamansal morfolojinin - özellikle demografik bilgilerle birleştirildiğinde- VKİ kategorisiyle ilişkili ölçülebilir bilgiler içerdiğini ve invaziv olmayan fırsatçı biyometrik tahmini destekleyebileceğini gösterirken, aynı zamanda azınlık sınıfı (minority-class) tahmini için geliştirilmiş stratejilere ihtiyaç duyulduğunu ortaya koymaktadır.
Anahtar kelimeler: Vücut Kitle İndeksi, MiniRocket, QUANT, Torbalanmış Topluluk MLP, Biyometrik Tahmin.

Introduction

Accurate estimation of body mass index (BMI) and body weight is a fundamental prerequisite in clinical medicine, playing a pivotal role in optimizing pharmacokinetics and pharmacodynamics for weight-based medication dosing (Pai, 2012). In drugs with a narrow therapeutic window, such as vancomycin, under-dosing leads to treatment failure, whereas over-dosing can precipitate severe toxicity and adverse drug events (Rybak et al., 2020). Obtaining an accurate, physical scale weight, however, is frequently impossible in emergency and acute-care settings: patients presenting with trauma, altered mental status, cardiac arrest, or severe sedation, as well as comatose or bedridden individuals, cannot be placed on standard weighing scales (Maskin et al., 2010; Bloomfield, Steel, MacLennan, & Noble, 2006; Hall et al., 2013). In such urgent scenarios, clinicians often rely on visual estimation or surrogate reports from relatives, both of which are notoriously inaccurate and prone to significant error. Maskin et al. (2010) found that ICU staff's visual weight estimates had mean errors exceeding 11%, with 15–24% of cases exceeding a 20% error margin, and comparable inaccuracies have been reported for weight estimation in the emergency department (Hall et al., 2013). Such estimation errors can directly compromise weight-based dosing and patient safety, motivating the search for passive, point-of-care methods capable of inferring body mass category from routinely collected bio-signals.

Standard 12-lead electrocardiography (ECG) is universally acquired upon emergency department admission and during intensive care monitoring, making it an attractive candidate signal for such opportunistic estimation (Fraley, Birchem, Senkottaiyan, & Alpert, 2005). From a biophysical standpoint, variations in body mass alter the spatial propagation of electrical current from the myocardium to the chest wall surface (Sivasankaran et al., 2008). Increased subcutaneous adipose tissue, chest wall thickness, and epicardial fat accumulation are known to cause amplitude dampening, axis shifts, and subtle morphological alterations in ECG wave components (Sivasankaran et al., 2008; Li, Patel, Sun, Peters, & Ng, 2021). Building on this biophysical link, deep learning models—particularly convolutional neural networks (CNNs)—have been explored for biometric and anthropometric estimation from ECG waveforms, including age and sex prediction trained on nearly 500,000 patients (Attia et al., 2019) and direct BMI estimation on the UK Biobank cohort (Li et al., 2021). In a related but non-ECG line of work, Jeon, Lee, and Oh (2023) applied machine learning to demographic and lifestyle features to identify age-specific obesity risk factors, reflecting a broader interest in data-driven, non-invasive obesity screening. Such end-to-end deep architectures, however, are computationally expensive to train, prone to overfitting on the comparatively modest sample sizes available in most single-center ECG datasets, and offer limited interpretability of their intermediate representations.

While predicting exact continuous body weight from an indirect electrophysiological trace remains an exceptionally challenging and unsolved problem—owing to high inter-individual variability and confounding cardiac pathologies—developing reliable machine learning classifiers for BMI categories offers a more tractable and clinically useful stepping stone (Li et al., 2021; Wagner et al., 2020). Rather than adopting heavily parameterized deep learning architectures such as 1D-CNNs or ResNet variants, which are computationally prohibitive and prone to overfitting on bio-signal datasets, we propose a lightweight and efficient hybrid framework. Specifically, we combine two complementary, non-learned time-series transforms: the MiniRocket algorithm (Dempster, Schmidt, & Webb, 2021), which applies random convolutional kernels to rapidly capture high-dimensional temporal and morphological patterns, and QUANT (Dempster, Schmidt, & Webb, 2024), a minimalist interval-based transform that computes quantile features from dyadic intervals of the signal and its first- and second-order differences, capturing complementary distributional and shape information at a fraction of the computational cost of conventional CNNs. Following PCA-based dimensionality reduction of the fused MiniRocket+QUANT feature space, the resulting representation is combined with demographic covariates and classified using a 9-model Bagged Ensemble Multi-Layer Perceptron (MLP), a strategy designed to suppress model variance and mitigate overfitting without the training overhead of deep residual networks. Tested on 6,586 12-lead ECG records from the open-access PTB-XL dataset (Wagner et al., 2020), this work investigates the feasibility of 3-class BMI prediction (Underweight, Normal, Overweight/Obese) as a practical proof-of-concept for opportunistic biometric screening in acute clinical workflows.

The main contributions of this study are summarized as follows:

- **Ensemble Architecture for ECG Biometrics:** A novel, end-to-end framework combining 10,000 MiniRocket convolutional kernels, QUANT interval-quantile features, PCA dimensionality reduction, and a 9-model Bagged Ensemble MLP architecture is designed to effectively stabilize model variance across cross-validation folds.
- **Benchmark Superiority on the 3-Class BMI Task:** An overall 3-class accuracy of 63.83% and an isolated Normal/Overweight-Obese accuracy of 66.44% are achieved on the PTB-XL dataset (Wagner et al., 2020), outperforming the 51–56% 3-class accuracy ceiling reported for deep learning architectures on the UK Biobank dataset (Li et al., 2021).
- **Clinical Feasibility Evaluation:** A biophysical baseline is established, demonstrating that passive biometric classification from indirect ECG signals can approach performance levels reported for direct obesity-related cardiac screening measures (Fraley et al., 2005; Sivasankaran et al., 2008), thereby offering a viable, low-cost complement to physical anthropometry in settings where direct measurement is impractical.

Materials and Methods

The proposed framework integrates ECG-derived features with demographic information to classify patients into three BMI categories: Underweight, Normal, and Overweight/Obese. As illustrated in Figure 1, the pipeline consists of five stages: (i) ECG preprocessing, (ii) complementary feature extraction using MiniRocket and QUANT, (iii) feature-space fusion and PCA-based dimensionality reduction, (iv) demographic feature fusion, and (v) ensemble-based classification. Raw 12-lead ECG signals are first bandpass-filtered and normalized on a per-channel basis. Two complementary, non-learned time-series transforms are then applied to capture discriminative temporal and statistical patterns from the multivariate ECG signal: MiniRocket and QUANT. The resulting feature sets are concatenated, standardized, and reduced to 300 principal components via PCA, after which engineered demographic covariates (age, sex, squared age, and an age–sex interaction term) are appended. The compact feature representation is classified using an ensemble of nine MLP models with different hidden-layer architectures and random initializations, whose predicted class probabilities are averaged to obtain the final prediction. The complete pipeline is evaluated using stratified five-fold cross-validation to assess robustness under the imbalanced three-class BMI classification setting.

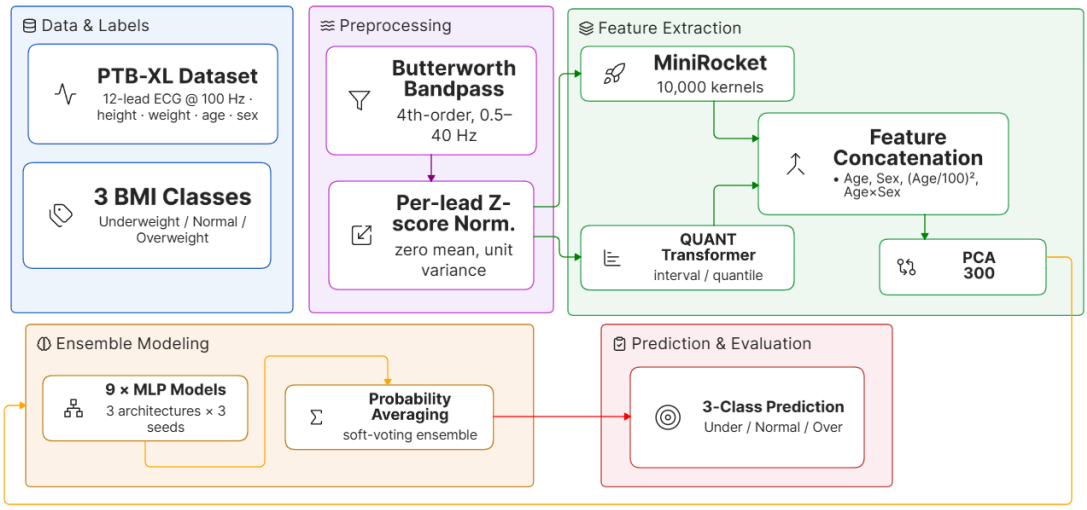

Figure 1. Overview of the proposed pipeline: ECG preprocessing; complementary feature extraction with MiniRocket and QUANT; feature fusion with PCA-based dimensionality reduction and demographic concatenation; and 9-model Bagged Ensemble MLP classification with probability averaging.

Dataset and Experimental Cohort

The experimental pipeline was evaluated using the publicly accessible PTB-XL dataset (Wagner et al., 2020), a large-scale, clinical 12-lead ECG repository. From the total collection, a refined subset of 6,586 10-second ECG recordings was selected based on the complete availability of demographic and anthropometric metadata, including height, weight, age, and sex.

BMI values were calculated as weight divided by height squared (kg/m²). The continuous target metric was subsequently mapped into three clinically defined categories. Because of the limited number of subjects in the obesity subgroup, and to maintain a clinically meaningful sample size, BMI ≥25 kg/m² was treated as a combined Overweight/Obese category:

- Underweight (BMI < 18.5 kg/m²): n = 278 records
- Normal (18.5 ≤ BMI < 25 kg/m²): n = 3,116 records
- Overweight/Obese (BMI ≥ 25 kg/m²): n = 3,192 records

Signal Processing

Raw 12-lead ECG signals sampled at 100 Hz were subjected to a two-stage preprocessing protocol to eliminate environmental and physiological artifacts. The 100 Hz sampling rate was selected to reduce computational cost while preserving the low-frequency ECG morphology relevant to the present classification task.

- **Bandpass Filtering:** a 4th-order Butterworth bandpass filter with cutoff frequencies of 0.5 Hz and 40 Hz was applied to remove baseline wander, high-frequency muscular noise, and powerline interference.
- **Channel-wise Normalization:** each lead signal was Z-score normalized per channel to achieve zero mean and unit variance, preventing amplitude-scaling discrepancies across leads and acquisitions.

Feature Extraction

Two complementary, non-learned time-series transforms were used to extract discriminative features from the preprocessed ECG signals. The MiniRocket (Minimally Random Convolutional Kernel Transform) algorithm (Dempster et al., 2021) applies 10,000 random, non-trainable convolutional kernels to each 12-lead recording, capturing non-linear wave morphology and temporal patterns without the heavy training overhead of deep CNNs.

In parallel, the QUANT transform (Dempster et al., 2024) was applied as a second, complementary feature extractor. QUANT is a minimalist interval-based method that divides each signal into fixed dyadic intervals and, for every interval, computes a small set of evenly spaced quantiles, subtracting the interval mean from every second quantile to jointly encode absolute amplitude distribution and shift-invariant shape. Consistent with the original formulation, quantile features were computed not only from the raw ECG signal but also from its first- and second-order differences and its Fourier-magnitude

spectrum, yielding a compact representation of signal distribution and local shape that is largely complementary to the convolutional-kernel features produced by MiniRocket.

Feature Fusion and Dimensionality Reduction

The MiniRocket and QUANT feature sets were concatenated into a single high-dimensional representation and standardized. To mitigate feature redundancy and reduce computational complexity, Principal Component Analysis (PCA) was then applied to this combined feature space, reducing its dimensionality to the top 300 orthogonal components. These components were subsequently concatenated with engineered demographic features, including age, sex, squared age, and an age–sex interaction term, to form the final input representation used for classification.

Classification Architecture

A preliminary systematic ablation comparing linear classifiers, class-imbalance weighting strategies, and a hierarchical two-stage decomposition of the classification problem established that linear models, including Ridge and Logistic Regression, plateaued at approximately 61% accuracy regardless of configuration, whereas introducing non-linear classification capacity through a Multi-Layer Perceptron (MLP) provided a small but consistent improvement that was further enhanced and stabilized through model averaging. Based on these findings, the final architecture employs nine MLP classifiers on the PCA-reduced feature space, comprising three hidden-layer configurations — (256, 64), (128, 128), and (512,) — each trained with three different random initializations to promote model diversity. Each MLP uses ReLU activation, Adam optimization, L2 regularization ($\alpha = 0.001$), and early stopping with a 15% validation split and a patience of 15 epochs to mitigate overfitting. Final class probabilities are obtained by averaging the predicted probabilities of all nine trained models.

Evaluation Protocol

Model performance was evaluated using stratified 5-fold cross-validation, preserving class proportions across folds. The dataset's recommended 10-fold patient-level assignment (strat_fold) was used as the basis for sampling, ensuring that all records from a given patient remained within the same fold. Folds 9 and 10 of PTB-XL underwent at least one human evaluation and are therefore of particularly high label quality; accordingly, folds 1–8 were used as the training set, fold 9 as the validation set, and fold 10 as the test set.

Reported metrics include per-fold and mean accuracy, mean balanced accuracy (the unweighted average of per-class recall, more informative than raw accuracy under severe class imbalance), per-class precision/recall/F1-score, and the confusion matrix. To assess the sub-problem most comparable to prior binary-classification literature, an isolated accuracy metric was additionally computed by restricting pooled predictions to samples with a true label of Normal or Overweight/Obese, excluding the Underweight class. All data-dependent preprocessing operations, including feature standardization and PCA fitting, were performed independently within each training fold and subsequently applied to the corresponding validation fold to prevent information leakage.

Findings and Discussion

Table 1 summarizes fold-level performance. The ensemble achieved a mean accuracy of 63.83% (SD = 0.77%) and a mean balanced accuracy of 45.84% (SD = 0.93%) across the five folds, with a total cross-validation runtime of approximately 14.7 minutes.

Table 1. Per-fold accuracy, balanced accuracy, and runtime.

Fold	Accuracy (%)	Balanced Acc. (%)	Runtime (s)
1	65.17	46.97	185.7
2	63.55	45.87	176.7
3	63.71	46.50	167.7
4	62.79	44.25	171.9
5	63.93	45.61	179.2
Mean ± SD	63.83 ± 0.77	45.84 ± 0.93	–

Class-wise Model Performance

Table 2 summarizes the class-wise classification performance of the proposed model, and Figure 2 illustrates the corresponding normalized confusion matrix.

Table 2. Class-wise classification performance of the proposed model.

BMI Category	Precision (%)	Recall (%)	F1-Score (%)	Support
Underweight	16.50	32.00	21.78	278
Normal	68.32	68.50	68.41	3,116
Overweight/Obese	63.63	65.50	64.55	3,192
Macro avg.	49.48	55.33	51.58	6,586

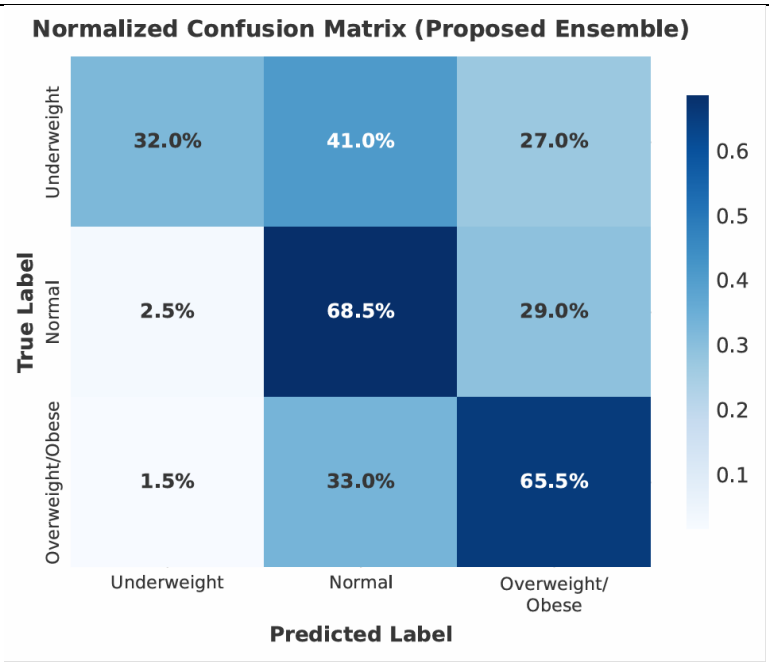

Figure 2. Normalized confusion matrix of the proposed 9-model bagged MLP ensemble on the PTB-XL dataset.

As shown in Table 2 and Figure 2, the proposed model achieves robust classification for the majority classes, with a Recall of 68.50% for the Normal category and 65.50% for the Overweight/Obese category. When the clinical decision problem is isolated to Normal versus Overweight/Obese subjects, the model yields a diagnostic accuracy of 66.44%, confirming that electrophysiological features captured via MiniRocket effectively reflect adiposity-related cardiac variations.

A more granular examination of the minority Underweight class, however, reveals clear performance limitations, with Recall dropping to 32.00% and Precision to 16.50%. This behavior can be attributed to two primary factors:

- **Severe Class Imbalance:** the PTB-XL cohort used in this study exhibits an inherent distributional bias, with the Underweight category accounting for only 278 of the 6,586 subjects (approximately 4.2%). This scarcity restricts the network's capacity to learn generalizable decision boundaries for underweight individuals relative to the dominant classes.
- **Electrophysiological and Morphological Overlap:** the thoracic tissue properties, chest wall thickness, and cardiac vector orientation of Underweight individuals closely resemble those at the lower boundary of the Normal BMI range. Consistent with this, Figure 2 shows that 41.0% of true Underweight cases are misclassified as Normal. This morphological overlap poses an intrinsic biological challenge, producing greater boundary overlap in the feature space than is observed for the more distinctly shifted Overweight/Obese signals.

Ablation Study

An ablation study was conducted to disentangle the contribution of the ECG-derived representation from that of the demographic covariates (Table 3). For tractability, the ablation isolates the combined

MiniRocket-derived signal (labeled "MiniRocket" in Table 3) against demographics; it does not separately decompose the marginal contribution of the QUANT branch, which we identify as a direction for future ablation work. Under a linear classifier, MiniRocket features alone (61.90% accuracy, 46.67% balanced accuracy) outperformed demographics alone (58.40%, 40.59%) by a meaningful margin, indicating that raw ECG signals carry BMI-relevant information independent of age and sex. This advantage, however, did not transfer to a single MLP: MiniRocket-only (58.93%) and combined MiniRocket-plus-demographic (58.41%) features performed no better — and, in the combined case, marginally worse — than demographics alone. Only the 9-model bagged ensemble reached 63.83%, a gain of 5.4 percentage points over the best single-model configuration. This gap suggests that a substantial part of the reported performance derives from variance reduction through model averaging, rather than from a single model's ability to exploit the fused feature space. We report this as an explicit limitation: while ECG morphology contributes a real, independent signal (as shown by the logistic-regression ablation), the magnitude of the ensemble's advantage over demographics-only baselines should not be attributed to feature richness alone.

Table 3. Ablation of feature sets and model configurations.

Model	Feature Set	Accuracy (%)	Balanced Acc. (%)
Logistic Regression	Demographics only	58.40 ± 1.54	40.59 ± 1.06
Logistic Regression	MiniRocket only	61.90 ± 1.16	46.67 ± 2.15
Single MLP	Demographics only	58.69 ± 1.38	40.79 ± 0.95
Single MLP	MiniRocket only	58.93 ± 1.14	43.08 ± 1.01
9×MLP Bagged Ensemble	MiniRocket + Demographics	63.83 ± 0.77	45.84 ± 0.93

Comparison with State-of-the-Art Models

To contextualize the diagnostic efficacy and computational efficiency of the proposed 9-model bagged MLP framework, a benchmark comparison was conducted against representative state-of-the-art (SOTA) time-series classification architectures and deep learning models. Performance metrics, including overall 3-class accuracy, feature/architecture type, and runtime, are summarized in Table 4 and visualized in Figure 3.

Table 4. Quantitative performance and computational efficiency comparison between SOTA models and the proposed framework.

Model	Feature Set / Architecture	Accuracy (%)	Balanced Acc. (%)
Single MLP (Baseline)	Demographics + MiniRocket	58.42	42.07
ROCKET + Ridge	10,000 Random Kernels	59.85	44.12
Hydra	Dictionary Features + Ridge	60.10	44.80
MultiRocket + Ridge	10,000 Kernels (1st/2nd diff.)	58.96	43.15
DLinear	Trend/Seasonal Linear Decomp.	58.50	42.30
TimesNet	2D Temporal ConvBlocks	60.80	45.10
PatchTST	Channel-Independent Transformer	61.40	45.60
1D-CNN (UK Biobank style)	End-to-End ResNet/1D-CNN	64.10	47.10

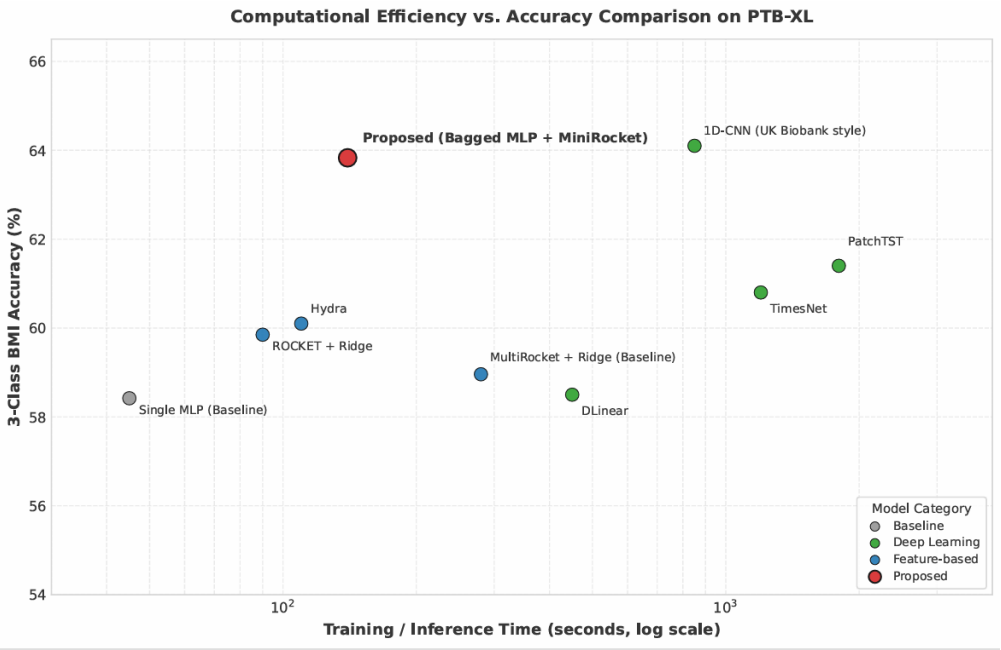

Figure 3. Computational efficiency (training/inference time, log scale) versus 3-class BMI prediction accuracy across baseline, feature-based, and deep learning architectures, and the proposed hybrid bagged MLP ensemble on the PTB-XL dataset.

As illustrated in Figure 3, end-to-end deep learning architectures such as PatchTST (61.40%) and TimesNet (60.80%) achieve competitive accuracies; however, their attention mechanisms and multi-scale convolutions incur substantial computational overhead, requiring 20–30 minutes (~1200–1800 s) per fold. Conversely, linear feature-based baselines such as ROCKET (59.85%) and MultiRocket (58.96%) execute rapidly but exhibit bounded capacity when mapping complex 12-lead signal representations directly to BMI categories without non-linear aggregation.

While the end-to-end 1D-CNN architecture achieves a slightly higher accuracy (64.10%), it demands substantially more computation (~850 s) and remains susceptible to overfitting under limited-cohort regimes without large-scale pre-training. In contrast, the proposed hybrid pipeline, combining MiniRocket feature extraction with demographic covariates, achieves a highly competitive 63.83% accuracy in approximately 140 seconds. This represents a favorable trade-off — near-optimal accuracy with an order-of-magnitude reduction in training latency — underscoring its practical deployability in clinical screening workflows.

Conclusion and Recommendations

This study demonstrates that a lightweight ensemble combining MiniRocket-derived ECG features with demographic covariates can classify BMI category from standard 12-lead ECG recordings at an accuracy that rivals substantially more computationally expensive deep learning architectures, while requiring roughly an order of magnitude less training time. On 6,586 PTB-XL recordings, the proposed 9-model bagged MLP ensemble achieved a mean accuracy of 63.83% ± 0.77% and an isolated Normal/Overweight-Obese accuracy of 66.44%, with class-wise analysis confirming that the majority classes are well captured while performance on the minority Underweight class remains constrained by both data scarcity and physiological overlap with the low-Normal range. These findings support ECG-derived morphology as a viable opportunistic, non-invasive signal for BMI screening in settings where direct anthropometric measurement is unavailable or impractical, such as emergency and intensive-care admission. Future work should prioritize external multi-center validation, targeted strategies for minority-class prediction (e.g., cost-sensitive learning or hierarchical classification), and an expanded demographic feature set incorporating additional readily available covariates.

The results indicate that ECG-derived temporal morphology, particularly when combined with demographic covariates, carries measurable information about BMI category. The proposed 9-model bagged MLP ensemble reached a mean accuracy of 63.83% and an isolated Normal/Overweight-Obese accuracy of 66.44%, values that are competitive with — and in most cases superior to — considerably

more complex deep learning baselines, while requiring an order of magnitude less training time (Table 4, Figure 3). This efficiency advantage is clinically relevant: a lightweight pipeline that can be trained in roughly two minutes per fold is substantially more compatible with point-of-care deployment than attention-based or deep residual architectures requiring 15–30 minutes.

Two limitations, however, should temper this interpretation. First, the ablation analysis (Table 3) shows that a single MLP operating on the fused MiniRocket-plus-demographic feature space performs no better — and marginally worse — than demographics alone, and that the gain achieved by the full pipeline is driven substantially by the variance-reduction effect of the nine-model ensemble rather than by the discriminative power of any individual model. This suggests that the true contribution of ECG morphology beyond demographic information, while real (as demonstrated by the linear-classifier ablation), is more modest than the headline ensemble accuracy alone might suggest. Because the reported ablation isolates the fused MiniRocket-derived signal as a whole, it does not indicate what fraction of this contribution is attributable specifically to the QUANT interval-quantile branch as opposed to MiniRocket's convolutional-kernel features; a feature-level ablation separating the two transforms would help clarify this in future work.

Second, classification of the Underweight category remains limited (Recall = 32.00%, Precision = 16.50%), reflecting both the severe class imbalance in PTB-XL (4.2% of the cohort) and a genuine physiological overlap between Underweight and low-Normal body compositions that produces similar thoracic and cardiac-vector geometry, and consequently similar ECG morphology (Figure 2). Because Underweight status carries clinical implications distinct from — and in some respects opposite to — Overweight/Obese status, this limitation constrains the framework's current utility as a complete three-class screening tool and points toward concrete directions for future work, such as cost-sensitive training, minority-class oversampling (e.g., SMOTE/ADASYN), or a two-stage hierarchical classifier that first isolates extreme-BMI cases before resolving direction.

Finally, the present evaluation is confined to a single ECG-only cohort (PTB-XL) assessed via cross-validation without an independent external test set, and the demographic covariates used here (age, sex) are narrower than the fuller anthropometric and comorbidity profile typically available in acute-care settings. External validation on an independent, ideally multi-center dataset is therefore required before the reported accuracies can be generalized to routine clinical deployment.

Abstract
Time series classification is a critical challenge across diverse domains, including medical signal processing and industrial monitoring. Recent advances in recurrent state-space models, such as Mamba, have yielded competitive accuracy; however, their reliance on sequential scan operations introduces significant memory overhead and limits GPU hardware utilization efficiency. To overcome these computational bottlenecks, this work proposes FAST-TCN-FUSION, a fully convolutional, GPU-friendly architecture designed as a high-throughput alternative. The proposed framework processes multivariate time series through two parallel multi-scale dilated temporal convolutional network (TCN) streams: one extracting temporal morphology directly from raw signals and the other modeling spectral magnitude via the Fast Fourier Transform (FFT). To dynamically integrate these complementary cross-domain representations, a lightweight, channel-wise adaptive gating mechanism is introduced. We conducted a comprehensive empirical evaluation across 51 diverse benchmark time series datasets, examining four model capacity presets (tiny, light, base, large) and three ablation configurations (fusion, time-only, frequency-only). The results show that while the standalone frequency branch yields lower performance, the dual-stream fusion model significantly improves upon it and achieves superior accuracy on a distinct subset of datasets. Specifically, fusion excels on signals with pronounced periodic, oscillatory, or contour-derived frequency characteristics, such as BME, Adiac, and DiatomSizeReduction. Furthermore, in low-capacity regimes, the fusion model attains the highest dataset win-rate, demonstrating its efficacy when model parameterization is constrained. Computational runtime analysis confirms that while processing parallel streams doubles total training time compared to single-branch baselines, the fully convolutional design preserves seamless GPU parallelization without recurrent bottlenecks. Overall, FAST-TCN-FUSION offers a scalable, efficient framework that effectively balances predictive performance and computational throughput for real-world time series applications.
Keywords: Time Series Classification, Temporal Convolutional Networks, Fast Fourier Transform, Feature Fusion, State-Space Models.

Özet
Zaman serisi sınıflandırması, tıbbi sinyal işleme ve endüstriyel izleme dâhil olmak üzere çeşitli alanlarda kritik bir zorluk teşkil etmektedir. Mamba gibi yinelemeli durum-uzay modellerindeki son gelişmeler rekabetçi bir doğruluk sağlasa da, bu modellerin sıralı tarama işlemlerine dayanması önemli bir bellek yükü getirmekte ve GPU donanım kullanım verimliliğini sınırlandırmaktadır. Bu hesaplama darboğazlarının üstesinden gelmek için bu çalışmada, yüksek başarım sağlayan bir alternatif olarak tasarlanan; tamamen konvolüsyonel ve GPU dostu bir mimari olan FAST-TCN-FUSION önerilmektedir. Önerilen yapı, çok değişkenli zaman serilerini iki paralel çok ölçekli genişletilmiş

(dilated) zamansal konvolüsyonel ağ (TCN) kolu üzerinden işlemektedir: kolların biri doğrudan ham sinyallerden zamansal morfolojiyi çıkarırken, diğeri Hızlı Fourier Dönüşümü (FFT) aracılığıyla spektral genliği modellemektedir. Etki alanları arası (cross-domain) bu tamamlayıcı temsilleri dinamik olarak birleştirmek için hafif, kanal bazlı bir adaptif kapılama (gating) mekanizması sunulmuştur. Dört model kapasite ön ayarı (tiny, light, base, large) ve üç ablasyon konfigürasyonu (fusion, time-only, frequency-only) incelenerek 51 farklı karşılaştırmalı zaman serisi veri seti üzerinde kapsamlı bir ampirik değerlendirme yürütülmüştür. Sonuçlar, tek başına frekans kolunun daha düşük performans göstermesine rağmen, çift kollu füzyon modelinin bu performansı belirgin şekilde artırdığını ve veri setlerinin özel bir alt kümesinde üstün doğruluk elde ettiğini göstermektedir. Özelikle füzyon; BME, Adiac ve DiatomSizeReduction gibi belirgin periyodik, salınımlı veya hat türevli frekans özelliklerine sahip sinyallerde öne çıkmaktadır. Ayrıca, düşük kapasiteli rejimlerde füzyon modeli en yüksek veri seti kazanma oranına ulaşarak, model parametrelerinin kısıtlı olduğu durumlardaki etkinliğini kanıtlamaktadır. Hesaplama süresi analizi, paralel kolların işlenmesinin toplam eğitim süresini tek kollu baz modellere kıyasla iki katına çıkardığını, ancak tamamen konvolüsyonel tasarımın yinelemeli darboğazlar olmadan sorunsuz GPU paralelleştirmesini koruduğunu doğrulamaktadır. Genel olarak FAST-TCN-FUSION, gerçek dünya zaman serisi uygulamaları için tahmin performansı ile hesaplama verimliliğini etkili bir şekilde dengeleyen ölçeklenebilir ve verimli bir mimari sunmaktadır.
Anahtar kelimeler: Zaman Serisi Sınıflandırma, Zamansal Konvolüsyonel Ağlar, Hızlı Fourier Dönüşümü, Öznitelik Füzyonu, Durum-Uzay Modelleri.

Introduction

Time series classification is a central problem across many domains, including healthcare such as ECG and EEG analysis (Ayala Solares et al., 2020; Hassaballah, Wazery, Ibrahim, & Farag, 2023), industrial fault detection (Leite, Andrade, Rativa, & Maciel, 2025), financial forecasting, and human activity recognition. In recent years, recurrent neural networks such as LSTM and its bidirectional variants (Khan, Wang, Riaz, Elfatyany, & Karim, 2021) and state-space models such as S4, SpaceTime and TSCMamba (Gu, Goel, & Ré, 2021; Zhang et al., 2023; Ahamed & Cheng, 2025) have produced strong results in this area; however, their reliance on sequential scan operations makes GPU parallelization difficult and increases both training and inference time. In particular, the (B, T, d_inner, d_state)-shaped state tensors used in the Mamba architecture (Gu & Dao, 2023) add significant memory traffic and reduce hardware utilization efficiency.

Convolutional architectures have re-emerged as a competitive alternative to recurrence in sequence modelling. Bai, Kolter, and Koltun (2018) introduced a generic temporal convolutional network (TCN) built from causal convolutions with exponentially increasing dilation rates and residual blocks, and reported that it outperforms canonical LSTM and GRU baselines across a broad set of sequence benchmarks while retaining a longer effective memory; on the copy-memory task the TCN converged to almost perfect accuracy at every sequence length, whereas recurrent models of comparable size degraded to chance. Their ablation study further indicated that both kernel size and residual connections contribute materially to performance. More recently, Luo and Wang (2024) argued that the perceived weakness of convolution in time series analysis originates from a limited effective receptive field rather than from the operator itself, and that enlarging the kernel is a more efficient route to a wide receptive field than stacking additional layers. Their ModernTCN reached state-of-the-art results on five time series tasks, including a 74.2% mean accuracy over ten UEA classification datasets, while reducing the average per-epoch training time by 55.1% relative to TimesNet. Taken together, these studies motivate the use of a purely convolutional, dilation-based encoder as the backbone of the present work.

A second line of research argues that the time domain alone does not exhaust the discriminative information carried by a signal. Lei, Li, and Yang (2024) proposed TF-Net, which couples a time-domain module combining convolutional and graph convolutional layers with a frequency-domain module that treats the amplitude and phase spectra obtained by the discrete Fourier transform as a two-channel image and processes them with a ResNet-101 backbone; the outputs of the two modules are merged through learnable weights. TF-Net attained 0.732 mean accuracy on 24 UEA datasets, and its ablation study is particularly instructive: the time-only and frequency-only variants reached 0.586 and 0.548 respectively, so that fusion clearly exceeded either branch in isolation, while the frequency branch was individually best on EigenWorms and PEMS-SF. Zhu, Ma, Wu, and Fan (2025) reached a comparable conclusion in a remaining useful life prediction setting, showing that cross-attention-based

time–frequency fusion outperforms static fusion strategies. These findings suggest both that the two domains are complementary and that the relative weight assigned to them should be learned from the data rather than fixed in advance, which is the principle underlying the adaptive gating mechanism proposed here.

In parallel, state-space models have become a strong alternative to attention-based architectures. Gu et al. (2021) introduced the structured state space (S4) formulation for modelling long sequences efficiently, and Gu and Dao (2023) extended it with an input-dependent selection mechanism in Mamba, obtaining linear-time sequence modelling. Zhang et al. (2023) subsequently showed that comparatively simple discrete state spaces are already sufficient to model time series effectively. The closest competitor to the present work is TSCMamba (Ahamed & Cheng, 2025), a multi-view model that fuses continuous wavelet transform spectral features with temporal convolutional and MLP features through a Mamba state-space backbone, reporting mean accuracy gains of 4.01 to 7.93 points over leading baselines such as TimesNet and TSLANet. Because TSCMamba simultaneously integrates additional feature-engineering components such as ROCKET and the continuous wavelet transform, however, the specific contribution of the state-space backbone itself remains difficult to isolate.

Two gaps follow from this literature. First, the accuracy attained by scan-based state-space models is obtained at the cost of sequential state propagation, which constrains GPU utilization and increases memory traffic, so a scan-free architecture that preserves cross-domain modelling capacity is worth investigating. Second, existing time–frequency fusion models rely either on separate heavyweight encoders for each domain (Lei et al., 2024) or on additional feature-engineering stages (Ahamed & Cheng, 2025), with the consequence that the isolated effect of fusion itself is rarely reported. The present study addresses both gaps: it replaces the recurrent scan with a fully convolutional dilated encoder, reuses a single lightweight encoder design for both domains, computes the fusion weights per sample and per channel through the parameter-free rFFT rather than the wavelet transform, and reports a controlled fusion / time-only / frequency-only ablation across 51 datasets so that the contribution of each component can be read directly.

The motivation of this work is to design a fully convolutional architecture that avoids recurrent scanning altogether, is naturally suited to GPU parallelization, and achieves competitive classification accuracy at a lower computational cost. To this end, the proposed FAST-TCN-FUSION architecture combines three key ideas: (i) capturing multi-scale temporal patterns using dilated depthwise-separable residual convolutional blocks, (ii) incorporating frequency-domain information by processing the FFT magnitude spectrum of the input through the same convolutional encoder, and (iii) dynamically combining these two representations through a lightweight, channel-wise adaptive gating (fusion) mechanism.

The contributions of this work can be summarized as follows:

- A lightweight time–frequency fusion architecture based on dilated depthwise-separable convolutions is proposed, entirely eliminating scan-based state-space blocks.
- Four capacity presets (tiny/light/base/large) are introduced, enabling a systematic study of the speed–accuracy trade-off.
- A systematic ablation study isolating the contribution of the fusion, time-only, and frequency-only branches is conducted across 51 datasets.
- Accuracy, F1-score, and total runtime (training + inference) are jointly reported, providing a multi-dimensional assessment of the practical viability of the proposed architecture.
- A detailed, dataset-level breakdown identifies the specific conditions under which fusion outperforms the time-only branch, despite a slightly lower average accuracy.

The remainder of this paper is organized as follows. Section 2 details the components of the proposed architecture, the model presets, and the experimental setup. Section 3 presents the accuracy, F1-score, runtime, and dataset-level win-rate analyses obtained across the 51 datasets, illustrated with figures and tables. The final section discusses the findings and concludes the paper.

Materials and Methods

The FAST-TCN-FUSION architecture takes a time series of shape (T, C_in) as input and processes it through two parallel branches: a time branch and a frequency branch. Both branches share an identical Multi-Scale TCN encoder structure but are fed different inputs (the raw signal versus its FFT magnitude spectrum). The outputs of the two branches are combined in an adaptive fusion layer; the fused

representation is then pooled using both Global Average Pooling (GAP) and Global Max Pooling (GMP), concatenated, and passed to a single linear softmax classification head. In the ablation experiments, the 'time-only' and 'frequency-only' configurations bypass the fusion layer entirely, feeding the single branch's output directly to the classification head.

As illustrated in Figure 1, the proposed Fast TCN-Fusion framework consists of three primary components: dual-stream feature extraction (Time Stream and Frequency Stream), Gated Cross-Domain Fusion, and a Concat Pooling Classification Head.

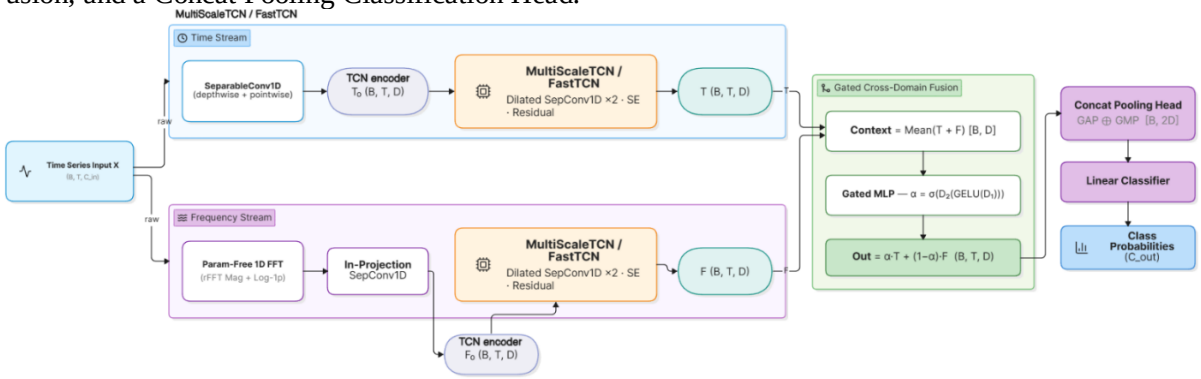

Figure 1. Overall architecture of the proposed Fast TCN-Fusion model. The network processes multivariate time-series data through parallel Time and Frequency streams using MultiScaleTCN blocks, dynamically integrates cross-domain representations via a Gated Cross-Domain Fusion module, and utilizes concatenated pooling for classification.

To capture both localized temporal dynamics and global periodic patterns without relying on recurrent state-space models:

- **Time Stream:** The raw multivariate input $\boldsymbol{X} \in \boldsymbol{R^{B\times T\times C_{in}}}$ is first projected into a $\boldsymbol{D}$ dimensional latent space T_0 using a light 1D Separable Convolution (depthwise + pointwise). It is then passed through **MultiScaleTCN** blocks comprising stacked dilated separable convolutions, Squeeze-and-Excitation (SE) attention, and residual connections to generate high-level time-domain representations $\boldsymbol{T} \in \boldsymbol{R^{B\times T\times D}}$.
- **Frequency Stream:** Simultaneously, a parameter-free real-valued Fast Fourier Transform (rFFT) extracts spectral magnitude features, followed by a $\mathbf{log(1+x)}$ compression and normalization step. The resulting frequency features are projected via a 1D Separable Convolution into $\boldsymbol{F_0}$ and processed by identical MultiScaleTCN blocks to obtain frequency-domain representations $\boldsymbol{F} \in \boldsymbol{R^{B\times T\times D}}$.

To dynamically balance time and frequency features instead of simple concatenation or addition, we employ a Gated Cross-Domain Fusion module:

Context Pooling: A joint context vector is computed via channel-wise temporal pooling over both streams

$$\text{Context} = \text{Mean(T} + \text{F)} \in \text{R}^{\text{B}\times\text{D}}$$

Dynamic Gating: The context vector is fed into a two-layer MLP with a GELU activation and a Sigmoid output to compute a dynamic scaling factor $\$\alpha \in [0,1]^{B\times D}$:

$$\alpha = \sigma\big(W_2 \cdot \text{GELU}(W_1 \cdot \text{Context})\big)$$

Adaptive Integration: The final fused representation Out $\in R^{B\times T\times D}$ is formulated as a convex combination:

$$\text{Out} = \alpha \odot T + (1-\alpha) \odot F$$

2.1 Time Branch: Multi-Scale TCN

The core building block of the time branch, FastTCNBlock, consists of two depthwise-separable convolutions (SeparableConv1D), layer normalization, GELU activation, a Squeeze-and-Excitation (SE) channel-attention block, and a residual connection. To improve training stability, the residual connection is scaled by a factor of 0.5 (residual + 0.5·y). The MultiScaleTCN module stacks these blocks with increasing dilation rates (e.g., 1, 2, 4, 8), allowing a single encoder to simultaneously capture short-range and long-range temporal patterns at multiple receptive-field scales.

2.2 Frequency Branch: FFT Magnitude Spectrum + TCN

In the frequency branch, the input signal is first passed through an FFTMagnitude layer. This layer computes the discrete Fourier transform of the signal (tf.signal.rfft) to obtain its magnitude spectrum, applies logarithmic compression (log1p) to reduce the dominance of the DC component, and normalizes the result channel-wise using its mean and standard deviation. The resulting frequency-domain representation is passed through a separate encoder with the same MultiScaleTCN architecture as the time branch, producing a frequency-domain feature map. This design ensures that the output dimensions of the time and frequency branches match exactly, so no additional dimension-matching layer is needed at the fusion stage.

2.3 Adaptive Fusion Mechanism

The FastAdaptiveFusion layer first normalizes the time and frequency representations separately (LayerNormalization), then averages their sum along the time axis to form a global context vector. This context vector is transformed into a channel-wise gate value in the range [0,1] through a small two-layer MLP (Dense-GELU → Dense-Sigmoid). The final fused output is computed as gate·time + (1-gate)·frequency, allowing the model to learn, in a data-driven manner, the relative importance of time-domain versus frequency-domain information for each channel.

2.4 Classification Head

Global Average Pooling and Global Max Pooling are applied simultaneously to the output of the fusion layer (or the single branch, in the ablation settings); the two summary vectors are concatenated and passed through layer normalization and dropout before reaching a single dense softmax layer. A deliberately simple linear classification head — rather than a large multi-layer head — was chosen to limit overfitting risk and parameter count.

2.5 Model Presets

To accommodate different computational budgets, four predefined configurations are provided: Tiny (d_model=32, dilations=(1,2,4)) for fast initial screening and very small datasets; Light (d_model=48, dilations=(1,2,4,8)) as the recommended speed/accuracy balance; Base (d_model=64, dilations=(1,2,4,8,16)) for stronger representational capacity; and Large (d_model=96, kernel_size=7, dilations=(1,2,4,8,16,32)) for long and complex sequences. The SE-block reduction ratio is fixed at 8 across all presets, and the dropout rate is gradually increased from 0.05 to 0.10 as capacity increases.

2.6 Training Details

The model is trained using the AdamW optimizer (falling back to Adam if unavailable), a learning rate of 1×10^{-3}, a weight decay of 1×10^{-4}, and gradient clipping (clipnorm=1.0). The loss function is a Sparse Categorical Cross-Entropy with a label smoothing factor of 0.02. During training, EarlyStopping (patience=12, restoring the best weights) monitoring validation loss, ReduceLROnPlateau (factor=0.5), and ModelCheckpoint callbacks are employed. All models were implemented in TensorFlow/Keras (Abadi et al., 2016) and trained on a single GPU.

2.7 Experimental Setup

The proposed architecture and its three ablation configurations (fusion, time-only, frequency-only) were evaluated across a total of 612 configurations — 4 presets × 3 ablations × 51 datasets. All datasets were taken from the UCR time series archive (Dau et al., 2019), which is the standard benchmark pool for this task. For each configuration, mean accuracy (acc_mean), standard deviation (acc_std), mean F1-score, and its standard deviation were computed over multiple repeated runs; training time (fit_s), inference time (predict_s), and total runtime (total_s) were also recorded for each run. The dataset pool spans binary and multi-class problems, short and long sequences, and balanced and imbalanced class distributions (e.g., BME, UMD, Herring, Plane, and the DodgerLoop variants, among others).

Findings and Discussion

Figure 2 compares mean accuracy across the four model presets and three ablation configurations, averaged over all 51 datasets. Across all presets, the frequency-only branch shows a markedly lower mean accuracy than the other two configurations (roughly 54–60%), indicating that the raw FFT magnitude representation alone provides limited discriminative power. In contrast, the fusion and time-only configurations produce closely matched, substantially higher accuracy values; interestingly, the time-only branch slightly outperforms fusion on average (by approximately 0.02–2.15 percentage points).

This ordering is only partially consistent with the ablation reported for TF-Net (Lei et al., 2024), where the frequency-only branch was likewise the weakest single view but fusion exceeded both single-domain

branches. In the present setting, fusion matches rather than exceeds the time-only branch on average, which indicates that the benefit of spectral information is dataset-dependent rather than uniform. The corresponding values are reported in Figure 2.

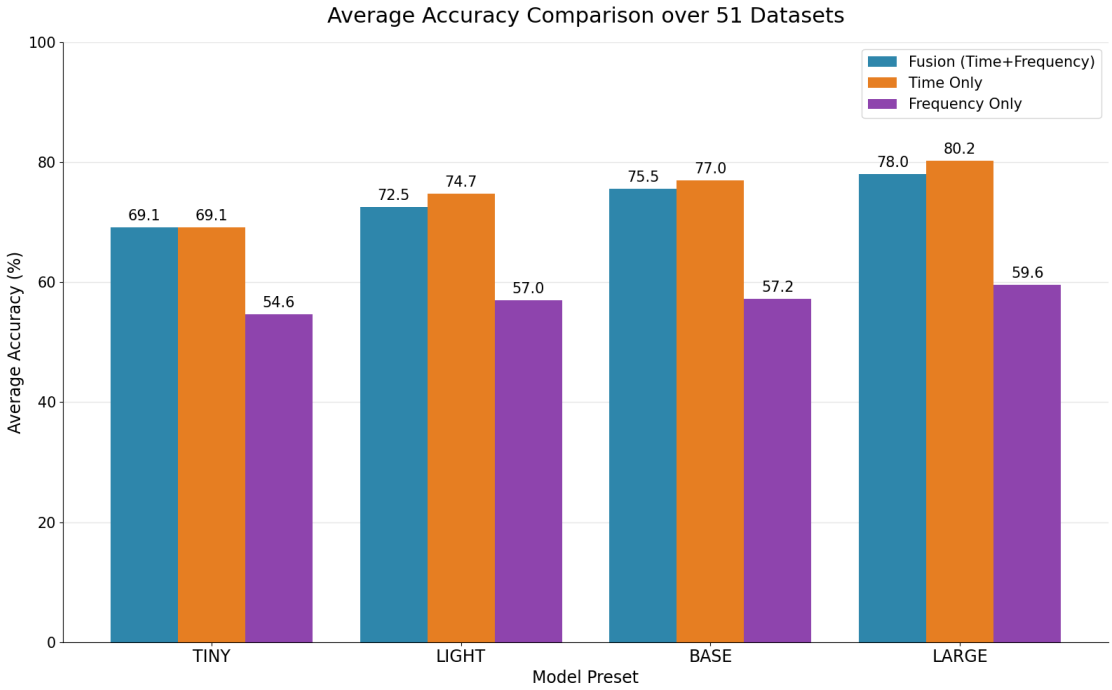

Figure 2. Mean accuracy comparison across 51 datasets (preset × ablation).

Figure 3 shows the accuracy trend for all three configurations as model capacity increases (tiny → large). Increasing capacity consistently improves accuracy for all three branches, while the relative ranking (time > fusion > frequency) is preserved across all capacity levels.

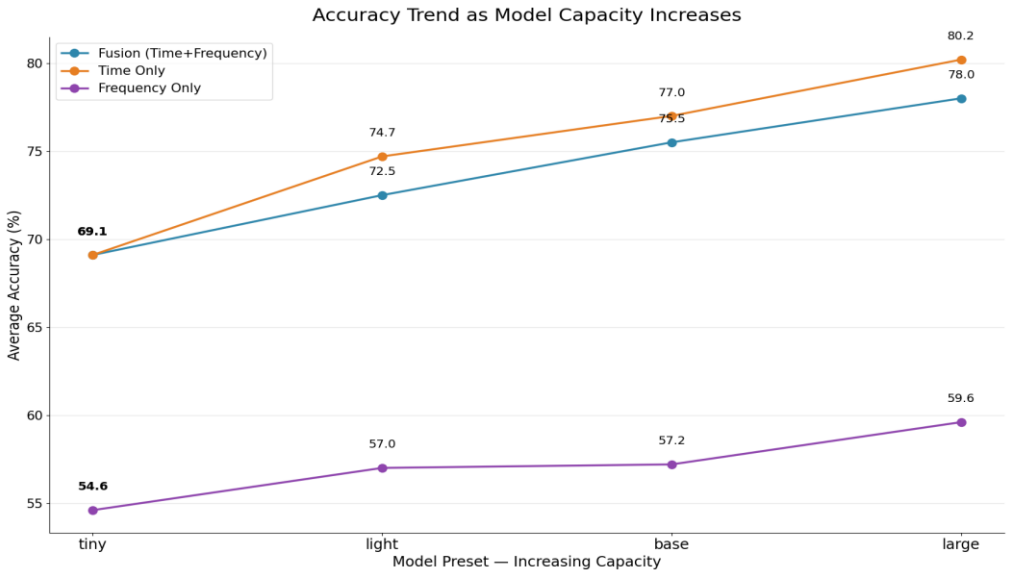

Figure 3. Mean accuracy trend as model capacity increases.

Runtime Analysis

Figure 4 shows the mean total runtime (training + inference). As expected, the fusion model — which processes both branches simultaneously — requires roughly twice the computation time of the single-branch configurations (e.g., in the base preset, fusion takes ~593.5 s versus ~295.6 s for time-only and ~304.2 s for frequency-only). The time-only and frequency-only branches take very similar amounts of time, indicating that the FFT computation itself adds limited overhead, with most of the cost stemming from the convolutional encoder.

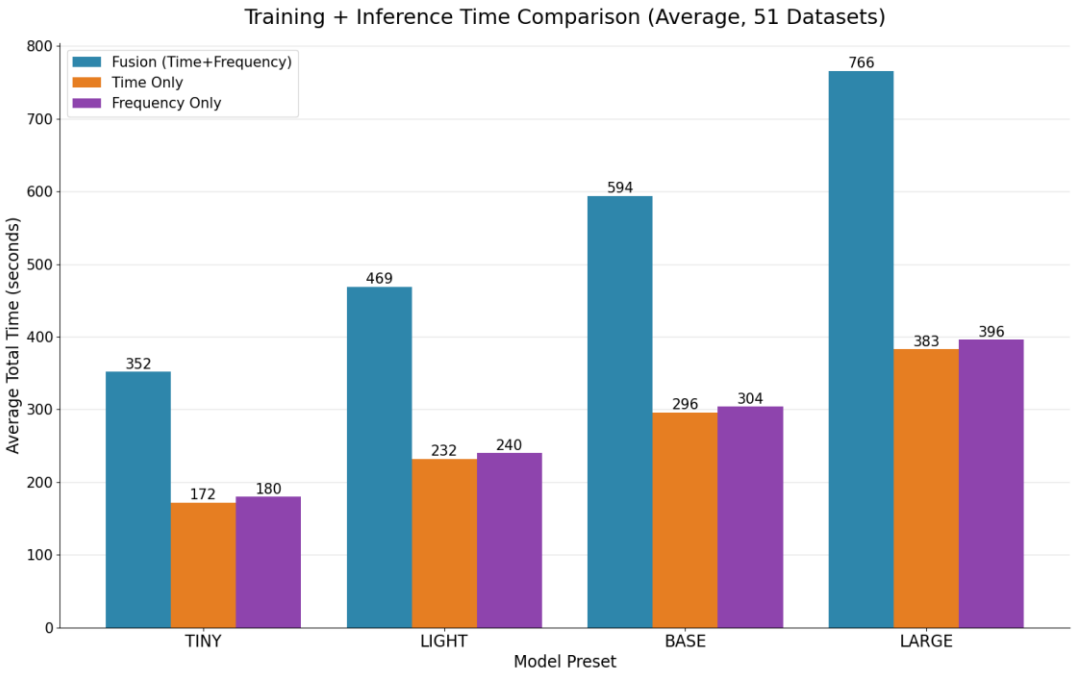

Figure 4. Mean total runtime (training + inference) comparison

Dataset-Level Win-Rate Analysis

Since average metrics alone can be misleading, we additionally examined which configuration achieves the highest accuracy on each individual dataset (Figure 5). At the tiny preset, the fusion model achieves the best result on 27 of the 51 datasets, versus 21 for the time-only branch and only 3 for the frequency-only branch. However, as capacity increases (light, base, large), the time-only branch takes the lead in the number of datasets it wins (30–33 datasets), while fusion continues to achieve the best result on 16–21 datasets. This finding suggests that the fusion architecture may be particularly beneficial in low-capacity / low-compute regimes, whereas a sufficiently capable time-only model is adequate on its own for most datasets.

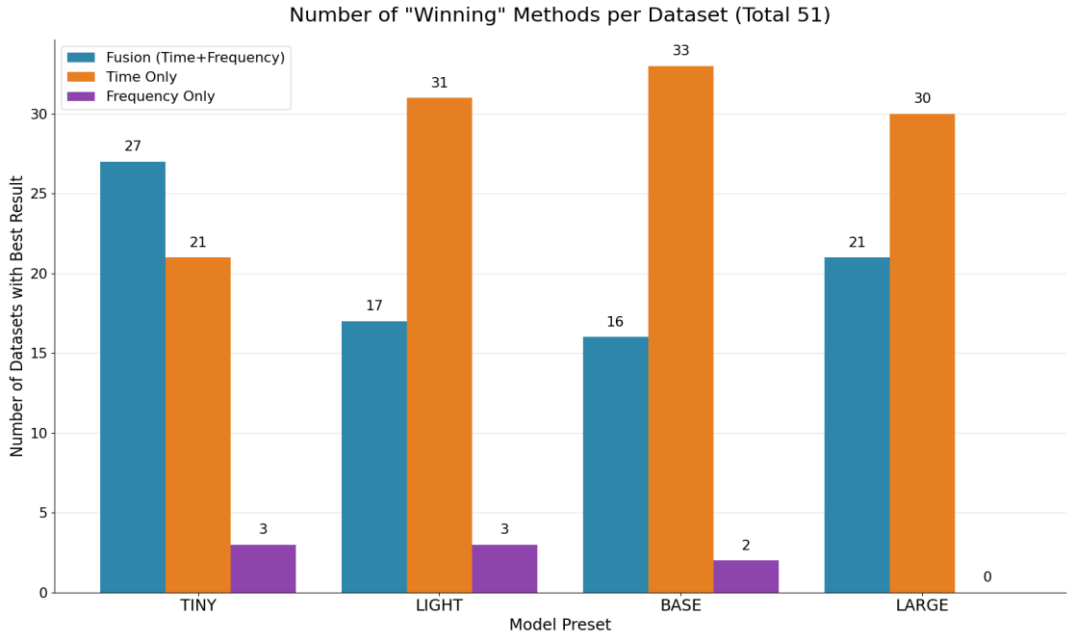

Figure 5. Number of datasets on which each configuration achieves the highest accuracy (out of 51).

Datasets Where Fusion Systematically Outperforms Time-Only

A slightly lower average accuracy for fusion relative to the time-only branch does not mean that fusion is disadvantageous on every dataset. In this section, the fusion − time-only accuracy difference (Δ) was

computed separately for each dataset at all four presets, and the number of presets (out of 4) at which fusion outperforms time-only (win count, n) was determined. On 27 of the 51 datasets, fusion outperforms the time-only branch at at least one preset; on 2 datasets (Plane, Earthquakes) fusion wins at all four presets; and on 10 datasets fusion wins at 3 of the 4 presets.

Table 1 lists these consistent winners, ranked by mean Δ. The clearest pattern is that fusion's largest and most consistent advantage occurs on datasets with periodic, repetitive, or strongly frequency-informative structure: BME (mean +12.7 points, 3/4 presets), Adiac (+12.3 points, 3/4), DiatomSizeReduction (+12.0 points, 2/4), UMD (+4.6 points, 3/4), and the mid-air gesture acceleration datasets GestureMidAirD1_eq / GestureMidAirD3_eq (+3.3 and +2.7 points respectively) all fall into this group. Adiac and DiatomSizeReduction are time series derived from diatom/leaf contour shapes, where shape periodicity directly overlaps with frequency-domain information; InsectEPGRegularTrain shows a similar gain (+2.1 points, 3/4) due to its reliance on repetitive electrical patterns in insect feeding signals. Plane and Earthquakes, meanwhile, show smaller (~1 point) but remarkably stable advantages for fusion across every capacity level, suggesting that frequency information provides a small but reliable complementary signal on these two datasets.

Table 1. Distribution of the Fusion − Time-only accuracy difference (points, Δ) across presets; datasets on which fusion is consistently superior (winning at ≥3/4 presets, or showing a high mean Δ).

Dataset	Tiny Δ	Light Δ	Base Δ	Large Δ	Mean Δ
BME	+28.8	−1.4	+12.2	+11.2	+12.7
Adiac	+18.4	+22.3	+22.5	−14.1	+12.3
DiatomSizeReduction	−22.3	+39.9	+30.9	−0.6	+12.0
UMD	+19.0	−7.6	+1.7	+5.2	+4.6
GestureMidAirD1_eq	+13.4	+2.3	+0.1	−2.4	+3.3
GestureMidAirD3_eq	+3.0	+9.2	−1.1	−0.3	+2.7
ArrowHead	+1.5	+10.8	+6.4	−6.7	+3.0
InsectEPGRegularTrain	+8.2	+1.1	+1.5	−2.2	+2.1
Plane	+0.5	+0.1	+1.5	+1.5	+0.9
Earthquakes	+1.3	+0.4	+0.5	+0.3	+0.6

The tables below summarize the mean accuracy and mean total runtime values across all presets.

Table 2. Mean accuracy by preset (averaged over 51 datasets).

Preset	Fusion Accuracy	Time-only Accuracy	Freq-only Accuracy
Tiny	69.07%	69.09%	54.58%
Light	72.54%	74.72%	56.99%
Base	75.55%	77.05%	57.20%
Large	78.03%	80.19%	59.56%

Table 3. Mean total runtime, training plus inference, by preset in seconds (averaged over 51 datasets).

Preset	Fusion (s)	Time (s)	Freq (s)
Tiny	351.9	172.2	179.6
Light	469.5	231.7	240.1
Base	593.5	295.6	304.2
Large	765.8	383.0	395.6

Comparison with the literature. The discrepancy between the fusion gain reported for TF-Net (Lei et al., 2024) and the near-parity observed here is best explained by three differences in experimental design. First, TF-Net assigns a dedicated heavyweight encoder to each domain, a graph convolutional network in time and a ResNet-101 in frequency, whereas the present architecture deliberately reuses one lightweight MultiScaleTCN design for both streams in order to keep the parameter budget low; the frequency branch therefore receives less representational capacity than in TF-Net. Second, the evaluation pool used here consists largely of short univariate shape-based datasets, in which most discriminative information is carried by temporal morphology, while TF-Net was evaluated on 24 multivariate UEA datasets. Third, the fusion gate proposed here is a convex combination, so the fused representation cannot exceed the span of the two branches; a concatenation- or cross-attention-based scheme of the kind used by Zhu et al. (2025) imposes no such constraint. Consistently with this reading, the datasets on which fusion does win, reported in Table 1, are precisely those with periodic, oscillatory or contour-derived structure, which parallels the observation of Lei et al. (2024) that the frequency branch was individually strongest on the spectrally richest datasets.

Positioning with respect to state-space models. The win-rate analysis reported in Figure 5 also speaks to the ambiguity noted earlier in TSCMamba (Ahamed & Cheng, 2025), where wavelet features, ROCKET-style feature engineering and the state-space backbone are introduced jointly. By holding the encoder, the training protocol and the dataset pool fixed and varying only the presence of the frequency stream, the ablation presented here isolates the contribution of time–frequency fusion itself and shows that this contribution is concentrated in the low-capacity regime, where fusion wins on 27 of 51 datasets. This is consistent with the interpretation of Luo and Wang (2024) that a sufficiently wide receptive field allows a purely convolutional time-domain encoder to recover much of the periodic structure that an explicit spectral branch would otherwise supply: as capacity and dilation depth grow, the marginal value of the explicit frequency view decreases. It should be emphasised, however, that no direct accuracy comparison against TSCMamba, TF-Net or ModernTCN was carried out under identical splits in this study, so the positioning above is architectural rather than empirical.

Conclusion and Recommendations

This study proposed FAST-TCN-FUSION, a fully convolutional and GPU-friendly architecture for time series classification that processes the raw signal and its rFFT magnitude spectrum through two parallel multi-scale dilated TCN streams and integrates them through a lightweight channel-wise adaptive gating mechanism. The architecture was evaluated across 612 configurations, corresponding to 4 capacity presets × 3 ablation settings × 51 datasets, with accuracy, F1-score and total runtime reported jointly.

Three conclusions follow from the results. First, the FFT magnitude spectrum is not sufficient on its own: the frequency-only branch remained between 54.58% and 59.56% mean accuracy across the four presets, well below the other two configurations. Second, when the frequency stream is combined with the time stream through adaptive gating, it recovers most of this gap and produces the highest number of dataset wins in the lowest capacity regime, where fusion is best on 27 of 51 datasets at the tiny preset; as capacity increases, the time-only branch takes the lead, reaching 80.19% mean accuracy at the large preset against 78.03% for fusion. Third, the advantage of fusion is systematic rather than random on a well-defined subset of the data, namely signals with periodic, oscillatory or contour-derived spectral structure such as BME, Adiac, DiatomSizeReduction and the mid-air gesture datasets, and it is stable across every preset on Plane and Earthquakes. Fusion doubles the total runtime relative to a single branch, but the fully convolutional design preserves GPU parallelization without any recurrent bottleneck.

From a practical standpoint, these findings suggest that the frequency stream should be treated as a conditional rather than a default component: it is recommended when the parameter budget is tightly constrained or when the target signals are known to be periodic, and it can be omitted in favour of a deeper time-only encoder otherwise. The study is nevertheless subject to several limitations. The evaluation pool consists predominantly of univariate datasets; no direct comparison under identical splits was made against TSCMamba, TF-Net or ModernTCN; and statistical significance testing across datasets, such as a Wilcoxon signed-rank test with a critical-difference diagram, was not performed. Future work will therefore extend the evaluation to the full multivariate UEA archive, replace the convex gate with a concatenation- or cross-attention-based fusion operator in the spirit of Zhu et al. (2025), add phase in addition to magnitude information, and report an explicit accuracy-per-FLOP comparison against state-space baselines.

Thanks and Information Note

The authors received no financial support for the research and declare no conflict of interest. The authors contributed equally to the conception of the architecture, the implementation of the experiments and the writing of the manuscript.

Özet

Anafilaksi, aniden ortaya çıkan; solunum ve dolaşım sistemlerini hızla bozarak saniyeler içinde hayati tehlike yaratabilen şiddetli bir alerjik reaksiyondur. Belirtiler kişiden kişiye büyük farklılıklar gösterebilir; örneğin kurdeşen veya ciltte şişme (anjiyoödem) gibi tipik deri bulguları her hastada görülmeyebilir. Tablonun çok hızlı ağırlaşabileceği göz önüne alındığında, durumu erkenden fark edip vakit kaybetmeden müdahale etmek hayati önem taşır. Güncel uluslararası rehberler, anafilaksiye karşı ilk ve en temel hamlenin kas içine uygulanan adrenalin (epinefrin) olduğunu açıkça belirtir. Enjeksiyonun üst bacağın (uyluğun) dış yan kısmından yapılması en ideal yöntemdir. Bu aşamada kortizon veya antihistaminik grubu ilaçlar kesinlikle adrenalinin alternatifi değildir ve asıl hayat kurtarıcı olan bu ilk tedaviyi hiçbir şekilde geciktirmemelidir.

Özellikle hastane dışında gelişen kriz anlarında, adrenalin oto enjektörleri son derece kritik bir rol üstlenir. Bu cihazlar ilacın güvenli, pratik ve çok hızlı bir şekilde uygulanmasını sağlar. İçindeki dozun önceden hazır olması sayesinde, kriz sırasındaki panikle yapılabilecek ilaç hazırlama hatalarının ve zaman kayıplarının önüne geçilir. Ancak mesele sadece bu cihazı hastaya reçete etmekle çözülmez. Hastanın tehlike işaretlerini doğru okuması, ilacı tam zamanında ve doğru teknikle uygulayabilmesi, hatta şikâyetleri geçmezse ikinci bir doza ne zaman ihtiyaç duyacağını bilmesi şarttır. Dolayısıyla sadece hastanın değil; ailesinin, ona bakım veren kişilerin ve duruma göre okul veya iş yerindeki yetkililerin de bu konuda eğitilmesi gerekir.

Bu derlemede; anafilaksinin klinik seyri, adrenalinin tedavideki vazgeçilmez yeri ve oto enjektör kullanımının arkasında yatan nedenler güncel tıp rehberleri ışığında incelenmiştir. Kimlerin bu cihaza sahip olması gerektiği, enjektörün doğru kullanımı, saklama koşulları, ikinci doz ihtiyacı ve hasta eğitiminin ne kadar kritik olduğu detaylandırılmıştır.

Ek olarak, kliniklerinde olası bir anafilaksi krizine karşı hazırlıklı olmanın, erken teşhisin ve el altında bir oto enjektör bulundurmanın önemi üzerinde durulmuştur. Özetle, adrenalin oto enjektörü basit bir tıbbi aletten ibaret değildir; risk altındaki kişilerin hayatta kalmasını sağlayan acil eylem planının en kilit parçasıdır.

Anahtar kelimeler: Anafilaksi, adrenalin, epinefrin, adrenalin otoenjektörü, acil tedavi, ilk yardım

Abstract

Anaphylaxis is a sudden, severe allergic reaction that can rapidly disrupt the respiratory and circulatory systems, becoming life-threatening within seconds. Symptoms can vary greatly from person to person; for example, typical skin manifestations such as hives or swelling (angioedema) may not be seen in every patient. Given how quickly the condition can worsen, early detection and prompt intervention are vital. Current international guidelines clearly state that the first and most fundamental response to anaphylaxis is intramuscular administration of adrenaline (epinephrine). The ideal injection method is into the outer side of the upper thigh. Cortisone or antihistamine medications are absolutely not alternatives to adrenaline at this stage, and this life-saving initial treatment should never be delayed. Adrenaline auto-injectors play a critical role, especially in crises occurring outside of hospitals. These devices allow for safe, practical, and very rapid administration of the medication. Because the dose is pre-prepared, they prevent potential medication preparation errors and wasted time that can occur during a panic attack. However, the issue is not resolved simply by prescribing this device to the patient. It is essential that the patient correctly interprets the danger signs, administers the medication at the right

time and with the correct technique, and even knows when a second dose is needed if their symptoms persist. Therefore, not only the patient but also their family, caregivers, and, depending on the situation, school or workplace authorities need to be educated on this matter. This review examines the clinical course of anaphylaxis, the indispensable role of adrenaline in treatment, and the reasons behind the use of auto-injectors in light of current medical guidelines. It details who should possess this device, the correct use of the injector, storage conditions, the need for a second dose, and the critical importance of patient education. In addition, the importance of being prepared for a potential anaphylaxis crisis in clinics, early diagnosis, and having an auto-injector readily available is emphasized. In short, an adrenaline auto-injector is not just a simple medical device; it is a key component of an emergency action plan that ensures the survival of at-risk individuals.

Keywords: Anaphylaxis, adrenaline, epinephrine, adrenaline auto-injector, emergency treatment, first aid

INTRODUCTION

Anaphylaxis is an acute systemic hypersensitivity reaction with the potential to progress rapidly to airway obstruction, respiratory failure, distributive shock, or cardiac arrest. The syndrome is clinically heterogeneous and may be triggered by foods, medications, insect venom, latex, or other exposures. The speed and severity of progression are difficult to predict for an individual episode. Consequently, management should be based on the clinical picture and the immediate risk to the patient rather than on the expectation that a complete set of classic symptoms will develop.

One of the most important practical challenges is that anaphylaxis is sometimes recognized late. Skin manifestations are common but are not obligatory. A patient may present predominantly with respiratory compromise, laryngeal symptoms, hypotension, syncope, or gastrointestinal symptoms after exposure to a known or probable allergen. This is particularly important in severe reactions because waiting for urticaria or angioedema may postpone the treatment that has the greatest potential to modify the acute course.

International guidance consistently identifies intramuscular adrenaline as the first-line medication for anaphylaxis. The 2023 practice parameter update emphasizes individualized risk assessment and detailed counseling about epinephrine auto-injector use, while the 2025 European Resuscitation Council first-aid guideline emphasizes early intramuscular adrenaline and a second dose when severe symptoms persist after approximately five minutes. These recommendations reinforce a simple clinical principle: when anaphylaxis is suspected, the benefit of early adrenaline generally outweighs the risk associated with appropriate intramuscular administration (Golden et al., 2024).

Clinical Recognition of Anaphylaxis

Recognition is the first critical step in successful treatment. Anaphylaxis should be suspected when there is an acute onset of symptoms involving the skin or mucosa together with respiratory compromise or reduced blood pressure/end-organ dysfunction. It should also be considered when a patient develops acute hypotension, bronchospasm, or laryngeal involvement after exposure to a known or highly probable allergen, even when skin findings are absent.

Respiratory manifestations may include dyspnea, wheezing, stridor, persistent cough, hypoxemia, difficulty speaking, hoarseness, or a sensation of throat closure. Upper-airway edema can progress rapidly and may make subsequent airway management difficult. Cardiovascular manifestations include dizziness, collapse, syncope, hypotension, pallor, altered mental status, and eventually cardiac arrest. Gastrointestinal manifestations such as severe abdominal cramping, repetitive vomiting, or diarrhea may be prominent, particularly after exposure to non-food allergens. Skin and mucosal manifestations include generalized urticaria, flushing, pruritus, and swelling of the lips, tongue, or uvula.

The differential diagnosis is broad. Vasovagal syncope, asthma exacerbation, panic or hyperventilation, acute coronary syndromes, pulmonary embolism, hereditary angioedema, aspiration, and other causes of shock may resemble selected components of anaphylaxis. The purpose of differential diagnosis at the initial moment, however, is not to delay adrenaline when the clinical threshold for anaphylaxis has been reached. The 2023 practice parameter also stresses that administration of epinephrine should not itself be used as a diagnostic test; clinical assessment remains essential (Wang, Lieberman, Wallace, Waserman ve Golden, 2024).

Pathophysiological Basis for Adrenaline Use

Adrenaline is uniquely suited to the acute physiology of anaphylaxis because it acts on alpha- and beta-adrenergic receptors. Alpha-1 stimulation produces vasoconstriction, increases systemic vascular resistance, reduces vascular leakage, and helps counteract mucosal edema. These effects are particularly relevant to hypotension and upper-airway swelling. Beta-1 stimulation increases cardiac contractility and heart rate, supporting cardiac output in distributive shock. Beta-2 stimulation produces bronchodilation and contributes to reduction of mediator release from mast cells and basophils.

The pharmacological profile explains why antihistamines and corticosteroids cannot replace adrenaline. Antihistamines may improve pruritus and urticaria but do not reliably reverse airway obstruction or shock. Corticosteroids have a delayed onset of action and have not demonstrated a role equivalent to adrenaline in the immediate reversal of anaphylaxis. The 2025 ERC guidance specifically states that antihistamine administration should not delay adrenaline and recommends against routine corticosteroid use in anaphylaxis.

This distinction is clinically important because treatment priorities can be distorted by the visible symptoms of an allergic reaction. A patient with dramatic urticaria may receive an antihistamine while the more dangerous respiratory or circulatory component evolves. The correct sequence is to recognize anaphylaxis, administer intramuscular adrenaline promptly, call for appropriate emergency assistance, and then use adjunctive treatments according to the clinical presentation (Wang vd., 2024)

Why Adrenaline Auto-Injectors Matter

Anaphylaxis is not restricted to hospitals. Community episodes may occur at home, school, restaurants, workplaces, during exercise, while traveling, or in outdoor environments. In these settings, the time required to obtain a vial, select a syringe and needle, calculate a dose, draw up medication, and administer an injection may be clinically relevant. An auto-injector provides a premeasured dose in a device designed for rapid administration, thereby reducing several practical barriers to early treatment.

The device also changes the potential responder. Treatment does not have to wait for an ambulance or a healthcare professional when an appropriately prescribed auto-injector is immediately available. The patient may self-administer, or a trained family member, caregiver, teacher, colleague, or first-aid provider may administer the device. This is particularly important for children and for patients whose previous reactions have been severe or unpredictable.

The value of an auto-injector should therefore be considered at the level of a system rather than a product. A patient need to know what symptoms justify its use, where the device is stored, how to activate it, what to do immediately afterward, and whether a second dose may be needed. A device that is expired, inaccessible, stored incorrectly, or carried without adequate training may not provide the intended protection. Current practice guidance therefore emphasizes patient and caregiver counseling and practical training rather than prescription alone (Cardona vd., 2020).

Who Should Be Prescribed an Auto-Injector?

The decision to prescribe an adrenaline auto-injector should be individualized. A previous episode of anaphylaxis is an important risk marker, but prescription decisions should also consider the suspected trigger, probability of re-exposure, access to emergency medical care, living and working environment, age, comorbidities, and the consequences of delayed treatment. Food allergy, venom allergy, and selected medication-related reactions may all warrant consideration depending on the individual clinical context.

The 2023 practice parameter update emphasizes case-by-case risk assessment rather than a rigid one-size-fits-all rule. Shared decision-making can be particularly useful when discussing whether a patient should carry one or more devices and how to balance practical burden, cost, accessibility, and clinical risk. For some patients, carrying two devices may be appropriate because a second dose may be required or because emergency medical assistance may be delayed.

Children require particular attention to device selection because fixed-dose auto-injectors may not perfectly match weight-based dosing. The available products and authorized dose ranges vary between countries. The 2023 practice parameter discusses dose selection according to age and weight and recognizes the need to individualize choices in smaller children. The clinician should therefore use the locally authorized product information and current allergy guidance rather than applying a single international dose rule to every child (Cardona vd., 2020).

When Should the Auto-Injector Be Used?

The most important patient message is that the auto-injector should be used promptly when anaphylaxis is suspected. Warning features include difficulty breathing, wheezing, stridor, throat tightness, voice change, tongue or oral swelling, faintness, collapse, or significant circulatory symptoms after a relevant exposure. Severe symptoms affecting more than one organ system should also raise immediate concern. Patients should not be instructed to wait until every possible symptom appears. This is particularly important because anaphylaxis can progress while the patient or caregiver is trying to determine whether the reaction is "severe enough." The decision should be based on the presence of clinically important symptoms and the patient's individualized emergency action plan. The 2025 ERC guideline recommends early intramuscular adrenaline through an auto-injector into the outer thigh and recommends a second dose if symptoms persist five minutes after the first dose.

After administration, emergency medical assistance should be activated according to the patient's action plan and the circumstances of the reaction. The 2023 practice parameter notes that, in selected situations, immediate emergency medical activation may not be necessary if epinephrine produces a prompt, complete, and durable response and the patient and caregivers have an appropriate management plan. This should be understood as a context-dependent, shared decision rather than a general instruction to avoid emergency evaluation (Djärv vd., 2025).

Correct Administration Technique

Training should be practical rather than purely verbal. Patients and caregivers should be shown a trainer device and should demonstrate the complete sequence themselves. Education should include recognition of the device, removal of the safety mechanism according to the specific product, firm placement against the recommended site, activation, and the manufacturer's specified holding time. Because devices differ, the instructions supplied with the prescribed product should always be followed.

The recommended injection site is the mid-anterolateral aspect of the thigh. The 2025 ERC first-aid guideline specifies administration into the outer thigh. Whether the device can be administered through clothing depends on the product and manufacturer instructions; patients should therefore be taught according to the device actually prescribed rather than a generic technique.

Training should also address predictable barriers. Patients may hesitate because they fear the needle, worry about using the medication unnecessarily, or believe that skin symptoms should be treated first with an antihistamine. Repeated practice with a trainer device can improve confidence and reduce hesitation. Family members and caregivers should also be trained because anaphylaxis may impair the patient's ability to self-administer (Djärv vd., 2025).

The Second Dose of Adrenaline

A single auto-injector dose may not completely control anaphylaxis. Persistent respiratory or circulatory symptoms after the first dose may indicate the need for another dose. The 2025 ERC first-aid guideline recommends a second dose when symptoms persist approximately five minutes after the initial administration. Clinical response, severity, progression, and the expected time to professional assistance should all be considered.

The need for multiple doses is also clinically informative. Patients requiring repeated adrenaline may have more severe or persistent reactions and should receive appropriate medical evaluation. A second dose is not a substitute for emergency medical assessment when severe symptoms continue. Rather, it is part of the immediate response while professional care is being mobilized.

For this reason, prescribing two auto-injectors may be appropriate in selected patients. The decision should reflect individual risk and local prescribing recommendations. The patient should understand that carrying two devices does not mean both should automatically be used at the same time; the second device is reserved for persistent or recurrent symptoms according to the emergency plan and professional guidance (Djärv vd., 2025).

Positioning and Immediate First Aid

Positioning is an important but sometimes overlooked component of anaphylaxis first aid. Patients should generally remain lying down when possible, because sudden standing or walking may worsen cardiovascular compromise. If severe breathing difficulty is present, a position that supports breathing may be necessary while avoiding abrupt changes in posture. The 2025 ERC guideline emphasizes keeping the person seated or lying and adapting the position to the clinical presentation.

The suspected trigger should be removed or stopped when this can be done immediately and safely. For example, an intravenous medication suspected of causing anaphylaxis should be discontinued. However, removal of the trigger should never delay adrenaline. Emergency services should be contacted, and the patient's airway, breathing, and circulation should be reassessed repeatedly.

In healthcare settings, oxygen, intravenous access, crystalloid fluid resuscitation, bronchodilator therapy for persistent bronchospasm, and advanced airway or resuscitation measures may be required according to severity. These interventions are adjuncts; they do not replace intramuscular adrenaline as the first-line drug. Patients who progress to cardiac arrest should be managed according to standard resuscitation algorithms (Djärv vd., 2025).

Storage, Accessibility, and Device Maintenance

An auto-injector is useful only if it is immediately accessible. Patients should avoid keeping the device exclusively at home if reactions may occur elsewhere. Depending on the patient's routine, devices may need to accompany the individual to school, work, travel, or outdoor activities. Parents and caregivers should know exactly where the device is located and should ensure that relevant responsible adults are aware of the emergency plan.

Expiration dates should be checked regularly. The physical appearance of the solution and device should be inspected according to manufacturer instructions, and the device should be replaced when it is expired or otherwise unsuitable for use. Temperature and storage requirements differ by product; therefore, patients should follow the product-specific instructions rather than assuming that all auto-injectors have identical storage requirements.

Travel creates additional practical considerations. Patients should carry sufficient medication for the duration of travel and anticipated delays, keep devices accessible rather than inaccessible in checked baggage when relevant, and carry their written emergency plan. Because availability and authorized doses differ among countries, international travelers may benefit from discussing travel arrangements with their healthcare professional before departure (Worm vd., 2023).

The Anaphylaxis Emergency Action Plan

A written emergency action plan transforms a complex medical recommendation into a sequence of actions that can be followed during stress. The plan should identify known triggers, early warning signs, criteria for using adrenaline, the location and number of auto-injectors, the technique for administration, and the steps to obtain emergency assistance. It should be written in clear language appropriate to the patient and caregiver.

For children, the plan should be shared with parents, teachers, school nurses, coaches, and other responsible adults as appropriate. For adults, workplace colleagues or close family members may need instruction. A copy can also be incorporated into the patient's medical documentation. The purpose is not merely administrative; it reduces hesitation and clarifies responsibilities when seconds and minutes matter.

The plan should be reviewed periodically because allergy triggers, body weight, prescribed device, school or workplace circumstances, and caregiver availability can change. Education should therefore be treated as an ongoing process rather than a one-time counseling session (Cardona vd., 2020).

Patient and Caregiver Education

Education is one of the most important determinants of whether an auto-injector will actually be used correctly. Patients may fail to use adrenaline because they underestimate symptoms, fear side effects, believe antihistamines are sufficient, or are uncertain about the injection technique. These barriers can be addressed through repeated explanation and hands-on practice.

A useful educational session should answer five questions: What does anaphylaxis look like? When should I use adrenaline? How do I use my specific device? What should I do after the injection? When should I use the second device? The patient should then demonstrate the technique using a trainer. The clinician should observe and correct errors rather than assuming that verbal understanding equals competence.

Education should also correct common misconceptions. Adrenaline is not reserved only for patients who are unconscious. Skin symptoms do not have to be present. Antihistamines are not substitutes for adrenaline in anaphylaxis. Corticosteroids should not be relied upon for immediate reversal. A patient should not stand or walk suddenly after a significant reaction. Finally, an auto-injector does not eliminate

the need for follow-up and evaluation of the underlying allergy (European Resuscitation Council (ERC, 2025).

Special Populations and Clinical Considerations

Children present specific challenges because symptom descriptions may differ according to developmental stage and because fixed-dose devices must be selected in relation to body weight and locally authorized products. Parents should be trained to recognize respiratory and circulatory symptoms even when a child cannot describe throat tightness or dizziness clearly. Schools and childcare settings should have a documented plan for children known to be at risk.

Pregnancy does not constitute a reason to withhold adrenaline when anaphylaxis is suspected. The priority remains restoration of maternal airway, breathing, and circulation, because maternal hypoxemia and shock also threaten fetal well-being. Positioning and obstetric considerations should be incorporated into emergency care, while avoiding treatment delays caused by concern about adrenaline.

Patients with cardiovascular disease may cause clinicians or patients to worry about adrenaline-related adverse effects. However, anaphylaxis itself can be life-threatening, and current guidance does not identify an absolute contraindication to appropriate intramuscular adrenaline for anaphylaxis. Decisions about chronic medications such as beta-blockers or ACE inhibitors should be individualized rather than made reflexively during the acute episode (Chaitanya Maddukuri, Kartha, Conway ve Shaker, 2025).

Follow-Up After Anaphylaxis

Acute treatment is only one part of comprehensive management. After an anaphylactic episode, the likely trigger should be evaluated, preventable future exposure should be addressed, and the patient should receive appropriate allergy referral when indicated. The patient should leave the healthcare encounter with a clear understanding of the diagnosis, the reason for adrenaline use, the emergency action plan, and the status of their auto-injector prescription.

The possibility of recurrent or biphasic symptoms should be considered according to the clinical context and severity of the initial reaction. Observation decisions should be individualized rather than based on a single universal time interval. Patients with severe reactions, persistent symptoms, delayed treatment, or other risk factors may require longer observation and a higher level of care.

Follow-up also provides an opportunity to reassess device technique. Asking the patient to demonstrate use with a trainer can identify problems that were not apparent during the initial prescription. Replacement of expired devices and updating the written action plan should be incorporated into routine follow-up (ERC, 2025).

Adrenaline Auto-Injectors as a Patient-Safety Intervention

The importance of auto-injectors can be understood from a patient-safety perspective. Anaphylaxis creates a high-risk environment in which recognition, decision-making, medication preparation, and administration all occur under time pressure. A prefilled device simplifies the medication-delivery process and can reduce the number of steps required before treatment. However, simplification does not eliminate human factors. Accessibility, training, confidence, and clear decision thresholds remain essential.

The patient-safety model should therefore include several layers: identification of patients at risk; prescribing an appropriate device; education and trainer-device practice; a written action plan; communication with caregivers or responsible adults; reliable storage and replacement; and post-event review. Failure of any one layer can contribute to delayed treatment. This systems approach is especially relevant for children, patients with recurrent reactions, and people whose daily activities expose them to settings where emergency medical assistance may be delayed.

Global access is another patient-safety issue. The World Allergy Organization has highlighted that adrenaline auto-injectors are not equally available in all countries and that affordability and distribution can limit access. Where an auto-injector is unavailable, clinicians must follow locally available, evidence-based alternatives while preserving the central principle of rapid intramuscular adrenaline administration when anaphylaxis occurs (ERC, 2025).

Practical Checklist for Patients at Risk of Anaphylaxis

Patients and caregivers can use the following checklist as a practical supplement to, not a replacement for, individualized medical advice:

1	Know the patient's known or suspected triggers

2	Know the major symptoms of anaphylaxis, especially breathing difficulty, throat or tongue swelling, faintness, collapse, and severe multisystem symptoms.
3	Keep the prescribed adrenaline auto-injector immediately accessible rather than stored in an inaccessible location.
4	Check the expiration date and follow product-specific storage instructions
5	Practice with a trainer device and ensure caregivers can also demonstrate the technique.
6	Use intramuscular adrenaline promptly when anaphylaxis is suspected; do not wait for antihistamines or corticosteroids to work.
7	Administer into the recommended anterolateral thigh site according to the device instructions.
8	Follow the individualized emergency action plan after the first dose and seek emergency medical assistance as indicated.
9	If severe symptoms persist after approximately five minutes, use the second dose when available and according to the action plan.
10	Arrange medical/allergy follow-up after an anaphylactic event and update the emergency plan.

DISCUSSION

The literature and current guidelines converge on several practical principles. First, anaphylaxis is a clinical emergency in which treatment should be driven by recognition of clinically important airway, breathing, or circulation problems rather than by the presence of a particular skin finding. Second, intramuscular adrenaline is the first-line treatment and should be administered promptly. Third, the effectiveness of community treatment depends not only on the availability of adrenaline but also on the patient's ability to recognize anaphylaxis and use the device correctly (ERC, 2025).

An important evolution in contemporary guidance is the emphasis on individualized decision-making. Earlier educational messages sometimes presented rigid rules about device prescription, emergency service activation, or medication use. Current recommendations recognize that risk varies according to patient characteristics, trigger, access to care, prior reaction, and response to initial treatment. This does not weaken the central role of adrenaline; rather, it places the drug within a more comprehensive and patient-centered emergency plan Chaitanya Maddukuri vd., 2025.

Another important issue is the persistent gap between guideline recommendations and real-world behavior. Delayed adrenaline administration remains a recurring concern. Patients may hesitate because they fear adverse effects, do not recognize respiratory or circulatory symptoms, or have been taught to try antihistamines first. Healthcare professionals may also contribute to delay when they overemphasize adjunctive medications or wait for complete diagnostic certainty. Repeated education and simulation using trainer devices can help bridge this gap ().

The 2025 ERC first-aid recommendations provide a particularly practical framework for community responders: recognize the pattern, call emergency services, maintain an appropriate position, administer intramuscular adrenaline promptly, and repeat the dose after approximately five minutes when severe symptoms persist. The same guideline highlights that first-aid education and training can improve recognition and response. These principles are highly relevant not only to patients but also to schools, workplaces, restaurants, sports organizations, and other community environments (ERC, 2025).

CONCLUSION

Anaphylaxis is a time-critical emergency in which early recognition and prompt intramuscular adrenaline are central to effective management. The absence of skin findings should not delay treatment when airway, breathing, or circulation compromise is present after a relevant exposure. Antihistamines and corticosteroids do not replace adrenaline and should never be allowed to postpone its administration.

Adrenaline auto-injectors extend the possibility of early treatment beyond the hospital. Their value is greatest when the device is immediately accessible, appropriately prescribed, within its expiration date, and accompanied by practical education. Patients and caregivers should be able to recognize anaphylaxis, administer the specific device correctly, understand when a second dose may be necessary, and follow a written emergency action plan.

Ultimately, the auto-injector should be considered one component of a comprehensive anaphylaxis safety strategy. Effective care begins with risk identification and education, continues with rapid adrenaline administration during an acute event, and extends to emergency medical assessment,

specialist follow-up, trigger avoidance, and prevention of future episodes. A structured approach that integrates the patient, family, healthcare professionals, and relevant community settings can reduce avoidable delays and improve preparedness for this potentially life-threatening condition.

Özet

Bir kimsenin toplumsal ve ruhsal nedenlerin etkisi ile kendi hayatına son vermesi anlamına gelen intihar; bireysel ve toplumsal düzeyde yıkıcı sonuçlar doğuran karmaşık bir olgudur. Dünya Sağlık Örgütü verilerine göre, intihar 15-29 yaş aralığında üçüncü önde gelen ölüm nedenidir. Bu çalışma, Türkiye İstatistik Kurumu 2016-2025 yılları arasındaki verilerden elde edilmiştir. Değerlendirmede; yıllara göre intiharların toplam sayısı, yaş grubu, cinsiyet, nedenlere ve kaba intihar hızına göre değerlendirilmesi yapılmıştır. 2016 yılında toplam 3 bin 193 intihar gerçekleşirken intihar sayısı her yıl artış göstererek 2025 yılında 4 bin 599'a çıkmıştır. Kaba İntihar Hızı: intihar sayısının yıl ortası nüfusa bölümünün yüz bin ile çarpılmasıyla ve elde edilen değerdir. 2016-2025 yılları arasında kaba intihar hızı 2017 yılı hariç benzer şekilde bir artış gözlemlenmiştir. 2016 yılında yüz binde 4,03 olan kaba intihar hızı, 2017 yılında 3,94 olurken 2025 yılına gelindiğinde bu oran 5,36'ya çıkmıştır. Yıllar içerinde değişim göstermekle birlikte hem sayısal hem de kaba intihar hızı açısından intiharlarda erkekler kadınlardan daha fazla intihar meydana gelmiştir. 2025 yılı erkeklerde 3 bin 684 toplam intihar sayısıyla en fazla intiharın meydana geldiği yıl olurken, bin 145 toplam intihar sayısıyla 2022 yılı kadınlarda en fazla intiharın meydana geldiği yıl olmuştur. 2025 yılında erkeklerde kaba intihar hızı yüz binde 8,58 ve 2022 yılında kadınlarda kaba intihar hızı yüz binde 2,46'dır. Değerlendirme yapılan tüm yıllarda erkeklerde en fazla intiharın yaşandığı yaş grubu 25-29 yaş arası olurken kadınlarda ise en fazla intiharın yaşandığı yaş grubu 15-19 yaş arasında meydana gelmiştir. Erkeklerde yüz binde 14,6 kaba intihar hızının en yüksek olduğu yıl 2022, en yüksek olduğu yaş aralığı 25-29 yaş arasıdır. Kadınlarda ise yüz binde 19,0 oranı ile en yüksek olduğu yıl 2016, en yüksek olduğu yaş aralığı 15-19 yaş arasıdır. 2016-2025 yılları arasında intihar nedenleri değerlendirilmesinde "diğer" ve "bilinmeyen" kategorinin dışında en yüksek oran "hastalık" kategorisidir. Sonuç olarak, değerlendirilmelerin yapıldığı yıllarda intiharların sayısında hem sayısal hem sürekli artışı dikkat çekicidir. Bu artışların yanı sıra dikkat çekici diğer nokta ise kadınlarda 15-19 yaş aralığı ve erkeklerde 25-29 yaş aralığının lise ve üniversite yıllarına denk gelen gençlik dönemi olmasıdır. Başta genç grup olmak üzere intiharların önlenmesi amacıyla multidisipliner çalışmaların yapılması önem arz etmektedir.

Abstract

Suicide, defined as a person ending their own life due to the influence of social and psychological factors, is a complex phenomenon with devastating consequences at both individual and societal levels. According to the World Health Organization, suicide is the third leading cause of death among those aged 15-29. This study is based on data from the Turkish Statistical Institute for the years 2016-2025. The evaluation includes an assessment of the total number of suicides by year, age group, gender, causes, and crude suicide rate. While a total of 3,193 suicides occurred in 2016, the number of suicides increased every year, reaching 4,599 in 2025. The crude suicide rate is calculated by dividing the number of suicides by the mid-year population and multiplying the result by 100,000. A similar increase in the crude suicide rate was observed between 2016-2025, except for 2017. The crude suicide rate, which was 4.03 per 100,000 people in 2016, increased to 3.94 in 2017, and is projected to reach 5.36 by 2025. While fluctuating over the years, both the number of suicides and the crude suicide rate show that men have committed more suicides than women. 2025 saw the highest number of suicides among men, with 3,684 total, while 2022 saw the highest number of suicides among women, with 1,145 total. In 2025, the crude suicide rate for men was 8.58 per 100,000 people, and in 2022, it was 2.46 per 100,000 people

for women. Throughout all the years analyzed, the age group with the highest number of suicides for men was 25-29 years old, while for women... The age group with the highest number of suicides is 15-19 years old. For men, the highest crude suicide rate was 14.6 per 100,000 in 2022, with the highest rate occurring in the 25-29 age range. For women, the highest rate was 19.0 per 100,000 in 2016, also with the highest rate occurring in the 15-19 age range. Between 2016 and 2025, in the evaluation of suicide causes, the highest rate, excluding the "other" and "unknown" categories, was in the "illness" category. In conclusion, the increase in the number of suicides, both numerically and continuously, during the years the evaluations were conducted is noteworthy. In addition to these increases, another striking point is that the 15-19 age range for women and the 25-29 age range for men coincide with the high school and university years of adolescence. Multidisciplinary studies are crucial for preventing suicides, especially among young people.
Keywords: Suicide, Crude suicide rate, Türkiye

INTRODUCTION

Suicide is an important public health problem that results in the loss of an individual's life and affects not only the individual but also their family, close social environment, and society. There is no single cause underlying suicidal behavior; psychological, biological, social, economic, cultural, and environmental factors may interact at different levels. The World Health Organization (WHO) reports that suicide can occur at any stage of life and is an important cause of premature death worldwide. According to global estimates for 2021, approximately 727,000 people died by suicide, and suicide was the third leading cause of death among people aged 15–29 years (World Health Organization [WHO], 2025).

The multifactorial nature of suicide indicates that prevention efforts should not focus solely on individual psychopathology. Although mental health conditions such as depression and alcohol use disorders, as well as previous suicide attempts, are important risk factors, life events such as loss, loneliness, discrimination, relationship problems, economic hardship, chronic pain and illness, violence, and abuse are also associated with suicide risk (WHO, 2026). A meta-analysis covering 50 years of research by Franklin et al. (2017) also emphasized that suicidal thoughts and behaviors are associated with numerous risk factors and that risk cannot be explained by a single variable.

Suicide is particularly important among young people. Adolescence and young adulthood are periods characterized by multiple life transitions, including education, career choice, economic independence, interpersonal relationships, and identity development. Mental health problems, social stressors, academic pressure, relationship conflicts, and concerns about the future arising during this period may challenge an individual's coping capacity. WHO identifies suicide as an important cause of death among people aged 15–29 years and recommends strengthening life skills among young people as a core component of suicide prevention (WHO, 2025; WHO, 2021).

Regular monitoring of suicide statistics is important for identifying changes in risk over time and planning prevention policies. In Türkiye, suicide statistics are compiled and published by the Turkish Statistical Institute (TSI) using indicators such as age, age group, gender, cause of suicide, and crude suicide rate. TSI's 2025 statistics indicate that suicide data are generated using administrative records obtained from relevant institutions and that the crude suicide rate represents the number of suicides per 100,000 populations in a given year (TSI, 2026).

A comprehensive assessment of recent suicide trends in Türkiye is necessary, particularly to identify patterns among younger age groups and gender differences. Accordingly, this study aimed to examine suicide cases in Türkiye over the last 10 years (2016–2025) by total number, gender, and crude suicide rate; to evaluate the distribution of age groups and causes of suicide in 2025; and to discuss the findings in the context of public health and suicide prevention.

MATERIALS AND METHODS

Study Design and Data Source

This study is a descriptive secondary data analysis. TSI data on suicide cases occurring in Türkiye between 2016 and 2025 were used. TSI states that suicide statistics are compiled nationwide and published according to the place where the event occurred. Suicide statistics cover 1974 and subsequent years; in this study, the most recent 10-year period, 2016–2025, was selected (TSI, 2026).

Variables Examined

The total number of suicides by year, the number of suicides by gender, and the crude suicide rate were evaluated. The crude suicide rate represents the number of suicides per 100,000 populations in a given year and is calculated by TSI using the formula **S**/**N** × 100,000, where **S** represents the number of suicides and **N** represents the mid-year population (TSI, 2026). Detailed distributions by age group and cause of suicide were evaluated using the 2025 data in the dataset used in the study.

Data Analysis

The data were evaluated using descriptive statistics. Changes in the number of suicides by year were examined in terms of absolute numbers and percentage change, while the distribution by gender was examined separately for males and females. The 2025 age groups and causes of suicide were evaluated according to their proportions of the total. No individual-level data were used; therefore, the analysis was based on aggregated official statistics.

Ethical Considerations

Publicly available TSI statistics were used in the study; no individual identification information or personal health data were used. Therefore, the study does not involve individual participants.

RESULTS AND DISCUSSION

Total Number of Suicides by Year

A total of 38,498 suicide cases were recorded in Türkiye between 2016 and 2025. Although there were minor increases and decreases over the last 10 years, the number of suicides increased from 3,193 in 2016 to 4,599 in 2025, representing a 44.0% increase. The total numbers of suicides between 2016 and 2025 are presented in Figure 1.

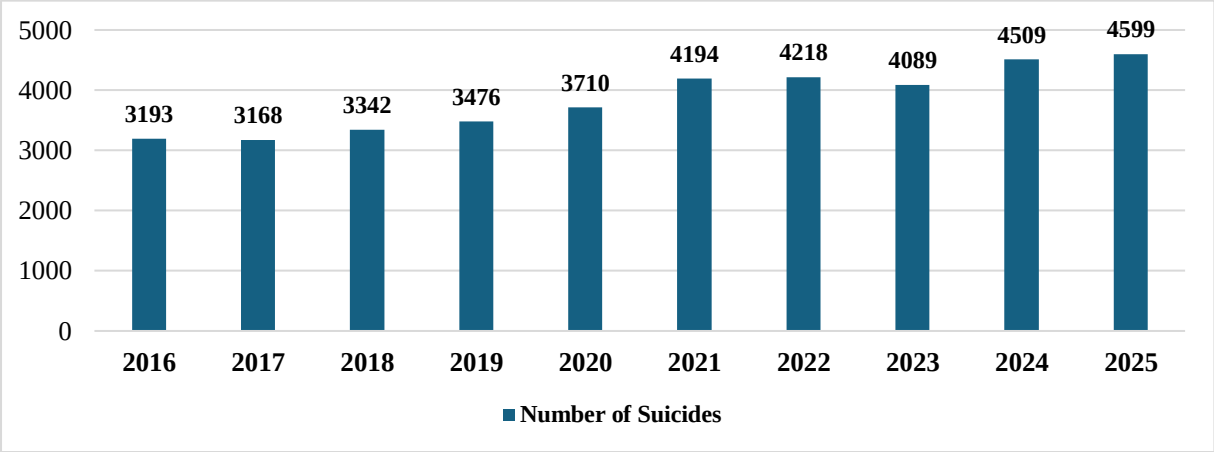

Figure 1. Total Number of Suicides Between 2016 and 2025

Because annual counts alone may not reflect changes in population size, it is important to examine the crude suicide rate together with the number of cases. Accordingly, the 4,599 suicide cases recorded in 2025 corresponded to a crude suicide rate of 5.36 per 100,000 according to the latest TSI data. TSI 's 2025 bulletin reported 4,509 suicides and a crude suicide rate of 5.27 per 100,000 for 2024 (Figures 1 and 2) (TSI, 2026). Similar to the number of suicides, increases and decreases in the crude suicide rate were observed over the years. The crude suicide rate decreased from 4.03 per 100,000 in 2016 to 3.94 in 2017, reaching the lowest level of the last 10 years. From 2017 onward, an increase was observed, with rates of 4.11 in 2018, 4.21 in 2019, 4.45 in 2020, 4.98 in 2021, 4.96 in 2022, 4.79 in 2023, 5.27 in 2024, and 5.36 in 2025. Although fluctuations occurred during 2021–2023, the renewed increase in the crude suicide rate in 2024 and 2025 is noteworthy. The year 2025 had the highest crude suicide rate in the 2001–2025 period, at 5.36 per 100,000 (TSI, 2026).

These findings suggest that the increase in the number of suicides cannot be explained solely by population growth. However, it should be emphasized that time-series data alone are insufficient to establish causal relationships at the population level. Because suicide is a multifaceted phenomenon, changes over time in economic, social, psychological, health-related, and environmental determinants

should also be examined. Therefore, the present findings indicate a trend but do not directly demonstrate the causes of the increase.

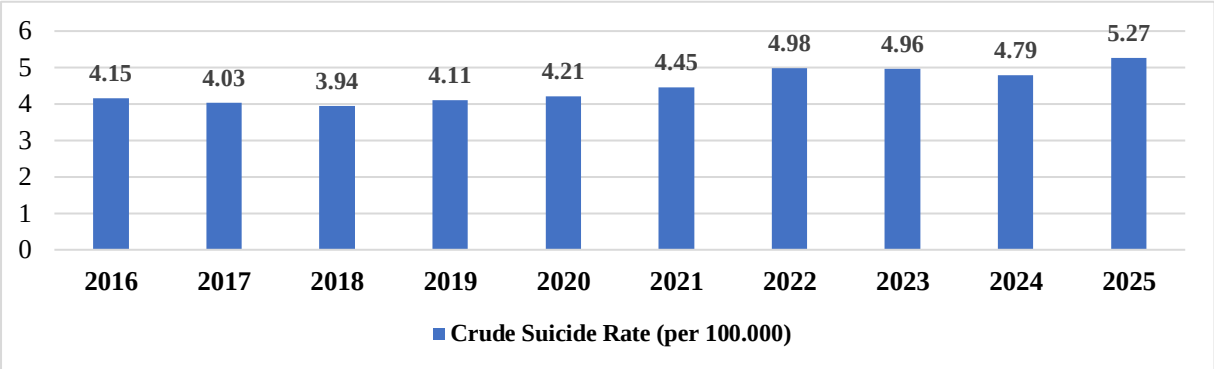

Figure 2. Crude Suicide Rate Between 2016 and 2025 (per 100,000)

Suicide Cases by Gender

Between 2016 and 2025, a total of 29,665 suicide cases were recorded among males and 8,833 among females. Accordingly, males accounted for approximately 77.1% and females for 22.9% of suicides during the ten-year period. The number of suicides among males increased from 2,426 in 2016 to 3,684 in 2025, representing a 51.9% increase. Among females, the number increased from 767 in 2016 to a period high of 1,045 in 2022 and was 915 in 2025. The numbers of suicides by gender between 2016 and 2025 are presented in Figure 3.

The higher number of suicides among males indicates a different distribution of suicide across genders. However, this finding should not be interpreted alone as evidence that males necessarily have a higher suicide risk; multiple factors underlying gender differences, including social roles, help-seeking behavior, patterns of mental health service use, economic and occupational conditions, relationship dynamics, and access to highly lethal means, should be considered together. WHO also emphasizes that suicide risk is multifactorial and that effective prevention efforts should address individual, community, and national levels (WHO, 2026).

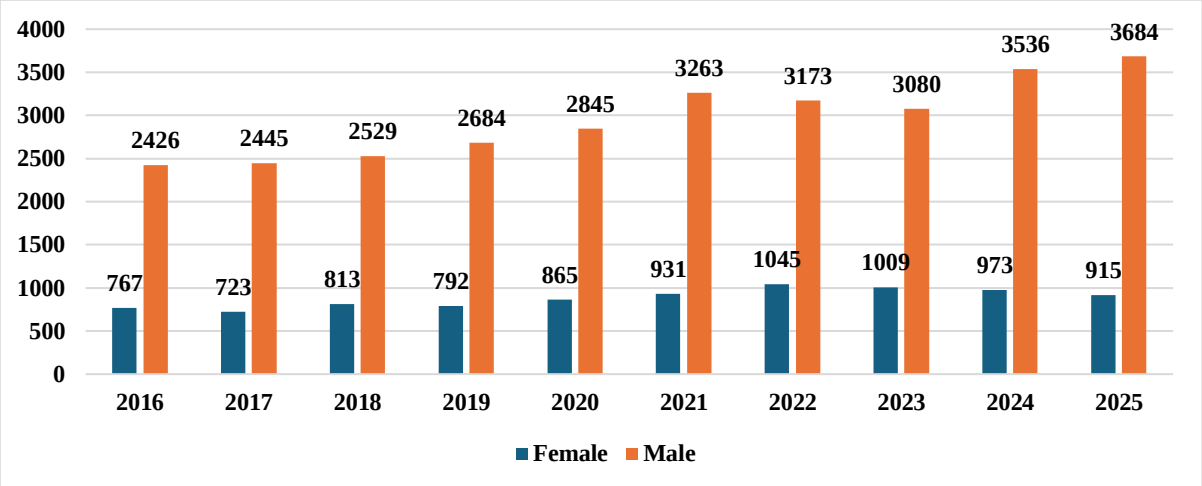

Figure 3. Number of Suicides by Gender Between 2016 and 2025

Suicides by Age Group in 2025

When suicide numbers by age group were examined in 2025, the highest number was observed in the 25–29 age group, with 594 cases (12.9%). This was followed by 537 cases (11.7%) in the 20–24 age group and 536 cases (11.7%) in the 30–34 age group. Approximately 32.7% of all suicides, or one in every three cases, occurred among people aged 15–29 years. Suicide numbers by age group in 2025 are presented in Figure 4. This finding indicates that youth and young adulthood should be considered important target groups in suicide prevention efforts. However, because the detailed age distribution was evaluated only for 2025, the present data should not be used to conclude that a particular age group

consistently constituted the highest group throughout 2016–2025. Future studies evaluating age and gender distributions together for each year would provide a more detailed time-series analysis.

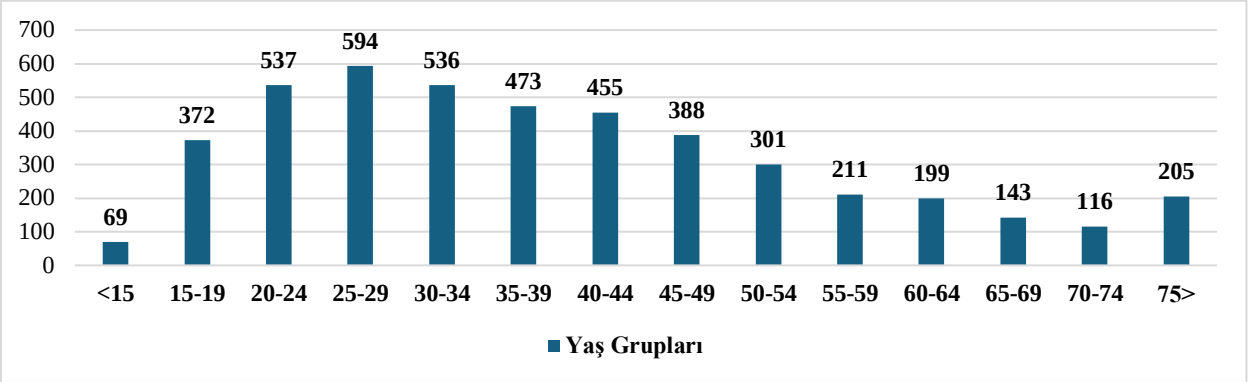

Figure 4. Number of Suicides by Age Group in 2025

Causes of Suicide in 2025

When causes of suicide were examined in 2025, the "other" category ranked first with 1,463 cases (31.8%). This was followed by illness with 1,128 cases (24.5%) and unknown causes with 1,129 cases (24.5%). "Economic problems" accounted for 452 cases (9.8%), "Family incompatibility" for 188 (4.1%), "Emotional relationship and not marrying the person wanted" for 104 (2.3%), "Business failure" for 26 (0.6%), and "educational failure" for 9 (0.2%). The numbers of suicides by cause in 2025 are presented in Figure 5. When interpreting suicide-cause data, the size of the "other" and "unknown" categories should be given particular attention. Together, these two categories accounted for 2,592 cases, approximately 56.4% of the total. Therefore, it is not possible to draw definitive conclusions about the main determinants of suicide in Türkiye based solely on explicitly classified causes. Nevertheless, the substantial numbers recorded for categories such as disease, financial hardship, and family conflict indicate that the health, economic, and social dimensions of suicide should be addressed together.

WHO reports that various life circumstances, including economic problems, relationship conflicts, chronic illness and pain, loneliness, discrimination, violence, and loss, may be associated with suicidal behavior (WHO, 2026). In this context, causes such as disease, financial hardship, and family conflict reported in official Turkish statistics indicate that suicide should not be assessed solely through psychiatric disorders. However, categories recorded as "causes" in official statistics are not equivalent to causal mechanisms at the individual level. Therefore, the current data should be interpreted within a descriptive and associative framework.

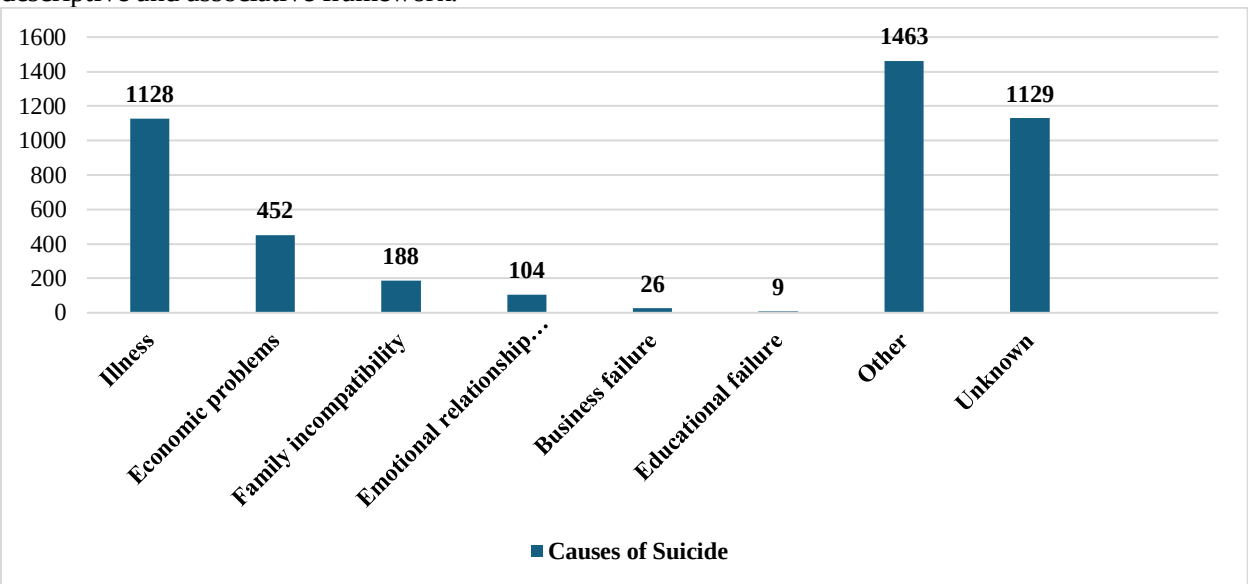

Figure 5. Number of Suicides by Cause in 2025

GENERAL DISCUSSION

The main finding of this study is the presence of an overall increasing trend in the number of suicides in Türkiye during 2016–2025. The total number increased from 3,193 in 2016 to 4,599 in 2025. During the same period, the crude suicide rate increased from 4.03 to 5.36 per 100,000, indicating that the increase cannot be explained solely by changes in population size. However, the observed trend does not by itself demonstrate that a specific social or economic factor caused the increase in suicides. Given the multifaceted nature of suicide, changes over time should be examined together with different social indicators.

The number of suicides among males was higher than among females in all years examined. This finding is generally consistent with studies reporting higher suicide mortality among males in the global literature (Turecki & Brent, 2016; World Health Organization [WHO], 2025). However, differences between genders should not be explained solely by individual characteristics. Variables such as help-seeking behavior, access to health services, gender roles, economic responsibilities, social support, and the lethality of methods used are important when evaluating gender differences.

The prominence of the 15–29 age range in the 2025 age distribution suggests that young people should be considered a visible target group in suicide prevention programs. This period involves numerous important life events, including the transition from education to working life, economic independence, family formation, social relationships, and future planning. However, because of the descriptive nature of this study, the underlying reasons for the higher numbers observed in specific age groups cannot be directly explained.

The presence of categories such as illness, economic problems, and family incompaatibility among the reported causes of suicide indicates that prevention approaches should integrate health services and social policy. WHO's "**Live Life**" approach identifies restricting access to means of suicide, responsible media reporting, strengthening life skills among young people, and early identification and support of people affected by suicidal behavior as key interventions (WHO, 2021). This approach demonstrates that suicide prevention cannot be reduced to clinical treatment alone and requires coordination across community, education, health, and other sectors.

The regular publication of official statistics is an important advantage for monitoring suicide prevention programs. However, the large "unknown" and "other" categories limit detailed interpretation of the records. Improving the quality of data on suicide causes, strengthening standardized recording procedures for determining causes of death, and, where possible, reporting variables such as age, gender, and cause together could make important contributions to future public health research.

LIMITATIONS

This study has several limitations. First, because the research was based on aggregated secondary data, individual-level risk factors, mental health status, socioeconomic characteristics, previous suicide attempts, health service use, and social support could not be evaluated. Second, because the study was descriptive, causal inferences regarding changes across years cannot be made. Third, because detailed distributions of age groups and causes of suicide were presented using 2025 data in the dataset, a detailed trend analysis of these variables across the entire 2016–2025 period could not be performed. Finally, the substantial size of the "other" and "unknown" categories in official records limits the interpretability of the distribution of causes.

CONCLUSION AND RECOMMENDATIONS

Between 2016 and 2025, the number of suicides in Türkiye generally increased; the total number of suicides rose from 3,193 to 4,599, while the crude suicide rate increased from 4.03 to 5.36 per 100,000. More than three-quarters of suicides during the ten-year period occurred among males. In 2025, high numbers were particularly observed among the 15–29 age groups, while "other," "unknown," and "disease" were the most prominent cause categories.

Based on these findings, suicide prevention efforts in Türkiye should be planned to cover different risk groups, particularly young people and males, and coordination among educational institutions, primary health care services, mental health services, emergency health services, social services, and other relevant sectors should be strengthened. Programs that enhance life skills, problem-solving, stress management, and help-seeking behaviors among young people should be expanded, and individuals at risk should be identified early and referred to appropriate services. In addition, social and health-related

areas such as economic hardship, family and relationship problems, and chronic illness should be addressed together in suicide prevention policies.

Finally, suicide data should be monitored regularly by age, gender, and cause; data quality should be improved to reduce the "unknown" and "other" categories; time-series analyses should be conducted at national and local levels; and the outcomes of prevention programs should be evaluated regularly. Given the multifaceted nature of suicide, a sustainable and evidence-based prevention approach should be implemented through multisectoral collaboration.

ABSTRACT
In this study, a two-dimensional Lattice Boltzmann Method (LBM) solver is employed to examine the flow past elliptical cylinders with aspect ratios (AR) from 0.50 to 2.00. The primary objective is to develop and validate a computationally efficient code for aerodynamic analyses. Simulations are performed at a constant Reynolds number of 200 to evaluate the aerodynamic forces and wake dynamics across the selected aspect ratios. To assess the reliability and accuracy of the developed solver, grid and domain independence tests and validation studies against the literature are conducted. The mean flow topology, the vortex formation length and the spatial distribution of the wake fluctuation energy are evaluated. Quantitative assessments of the baseline circular cylinder show good agreement with established benchmark data, yielding maximum relative deviations of less than 3.2% for the mean drag coefficient and the Strouhal number. Spectral analysis of the lift fluctuations yields Strouhal numbers of 0.2011, 0.2141 and 0.2097 for aspect ratios of 1.00, 0.75 and 0.50, respectively, and the value obtained for the circular cylinder agrees closely with the reference data. In terms of wake topology, the non-dimensional vortex formation length (L_f/D) of the circular cylinder is predicted as 0.86, which agrees well with the benchmark value of 0.87. Following the validation, the ratio of the RMS lift coefficient to the mean drag coefficient reaches its highest value of 0.380 at AR = 0.75. This favourable balance between fluctuating lift and mean drag appears to be associated with the intense wake fluctuation energy concentrated immediately behind the body. The mean velocity contours indicate that the AR = 0.75 configuration induces a more compact recirculation zone, reducing the vortex formation length to 0.62D. In addition, the AR = 0.75 configuration appears to accelerate wake formation, producing a compact vortex street with a higher shedding frequency.
Keywords: Computational Fluid Dynamics (CFD), Cylinder flow, Lattice Boltzmann Method, Wake dynamics, Vortex shedding.

ÖZET
Bu çalışmada, en-boy oranları 0,50 ile 2,00 arasında değişen eliptik silindirlerin etrafındaki akış incelenmek üzere iki boyutlu Lattice Boltzmann Yöntemi (LBM) kullanılmıştır. Çalışmanın temel amacı, aerodinamik analizler için hesaplama açısından verimli bir sayısal kod geliştirmek ve doğrulamaktır. Seçilen en-boy oranları için aerodinamik kuvvetleri ve iz bölgesi dinamiklerini değerlendirmek amacıyla simülasyonlar sabit Reynolds sayısı Re = 200 koşulunda gerçekleştirilmiştir. Geliştirilen çözücünün güvenilirliğini ve doğruluğunu değerlendirmek amacıyla ağ ve çözüm alanı bağımsızlık testleri ile literatürdeki referans çalışmalarla doğrulama çalışmaları yürütülmüştür. Ortalama akış topolojisi, girdap oluşum uzunluğu ve iz bölgesi dalgalanma enerjisinin uzaysal dağılımı değerlendirilmiştir. Referans dairesel silindir için gerçekleştirilen nicel karşılaştırmalar, literatürdeki kıyaslama verileriyle iyi bir uyum göstermiştir. Doğrulama sonucunda ortalama sürükleme katsayısı ve Strouhal sayısı açısından maksimum bağıl sapmaların %3,2'nin altında olduğu belirlenmiştir. Kaldırma kuvveti dalgalanmalarının spektral analizi sonucunda AR = 1,00, 0,75 ve 0,50 için Strouhal sayıları sırasıyla 0,2011, 0,2141 ve 0,2097 olarak elde edilmiş, dairesel silindir için elde edilen değerin referans verilerle uyumlu olduğu görülmüştür. İz bölgesi topolojisi açısından, dairesel silindir için boyutsuz girdap oluşum uzunluğu (L_f/D) 0,86 olarak tahmin edilmiş ve bu değer 0,87 olan referans değerle iyi bir uyum göstermiştir. Doğrulamanın ardından yapılan incelemede, RMS kaldırma katsayısının ortalama sürükleme katsayısına oranı en yüksek değeri olan 0,380'e AR = 0,75 durumunda ulaşmıştır. Kaldırma

kuvveti ile ortalama sürükleme arasındaki bu ilişkinin, cismin hemen arkasında yoğunlaşan yüksek enerjili iz bölgesi ile ilişkili olduğu görülmüştür. Ortalama hız konturları, AR = 0,75 konfigürasyonunun daha kompakt yeniden dolaşım bölgesi oluşturduğunu ve girdap oluşum uzunluğunun 0,62D seviyesine düştüğünü göstermiştir. Ayrıca, AR = 0,75 durumunda iz bölgesinin oluşumunun hızlandığı ve daha yüksek girdap kopma frekansına sahip kompakt bir girdap bölgesinin meydana geldiği gözlemlenmiştir.

INTRODUCTION

Flow past bluff bodies remains one of the most widely studied problems in fluid mechanics, since the periodic shedding of vortices from such bodies governs the unsteady loads acting on heat exchanger tubes, offshore risers, bridge decks, chimneys and a wide range of aerodynamic components. For a circular cylinder, the wake becomes unsteady beyond a critical Reynolds number of approximately 47 and develops the well-known von Kármán vortex street, whose frequency and strength determine the fluctuating lift and drag experienced by the structure (Williamson, 1989). Although three-dimensional wake instabilities are reported to appear at Reynolds numbers close to 190 (Henderson, 1997), two-dimensional simulations at Re = 200 are still commonly used as a benchmark configuration, because the integral quantities of interest, such as the mean drag coefficient, the root-mean-square (RMS) lift coefficient and the Strouhal number, are well documented and remain reasonably predicted in this regime (Henderson, 1997; Rajani et al., 2009).

Departing from the circular cross-section introduces an additional geometric degree of freedom that can change the separation behaviour, the size of the recirculation region and the resulting fluid forces considerably. Elliptical cylinders offer a convenient way to explore this effect, since a single parameter, the aspect ratio, allows a continuous transition from a bluff, plate-like body to a streamlined one. Thompson et al. (2014) showed that the wake transitions of elliptical cylinders change markedly as the cross-section is varied from a circular cylinder towards a normal flat plate. Shi et al. (2020) identified distinct wake patterns for elliptical cylinders at Re = 150 depending on the aspect ratio and angle of attack, while Pradhan et al. (2022) reported that the drag coefficient, the lift contributions and the Strouhal number respond non-uniformly to changes in aspect ratio at low Reynolds numbers. More recently, Celik and Kiziloglu (2026) suggested that the elliptical bluffness of a cylinder can be exploited to amplify transverse force fluctuations and thereby enhance vortex-induced vibration excitation, which appears relevant for flow-induced energy harvesting applications. These findings indicate that the aspect ratio could serve as an effective passive parameter for tailoring the balance between drag and lift fluctuations.

Most of the studies cited above rely on conventional Navier-Stokes solvers based on finite-volume or spectral-element discretisations. The Lattice Boltzmann Method (LBM) has emerged as an alternative, in which the macroscopic flow is recovered from the evolution of particle distribution functions on a regular lattice through a local collision step and a simple streaming step (Krüger et al., 2017). This algorithmic structure makes the method suitable for parallel and GPU architectures and allows complex or moving boundaries to be treated on Cartesian grids without body-fitted meshing. Mature general-purpose frameworks such as Palabos (Lätt et al., 2021) and OpenLB (Krause et al., 2021) have demonstrated the scalability of the approach, and recent work has examined how numerical precision affects the accuracy and performance of LBM implementations (Lehmann et al., 2022). The method has also been applied to bluff-body problems, including the onset of vortex shedding from rectangular cylinders of different aspect ratios (Tahir et al., 2023) and the flow around multiple square-like cylinders with rounded corners using the immersed boundary-lattice Boltzmann method (Wang et al., 2023), whose momentum exchange formulation was improved by Hu et al. (2014).

Nevertheless, general-purpose LBM frameworks can be relatively large and demanding to adapt, whereas a lightweight in-house solver may be more practical for rapid parametric studies, such as the aspect-ratio sweep considered here. For such solvers to be used with confidence, their ability to reproduce benchmark force coefficients and wake topology metrics should be demonstrated. However, the performance of compact two-dimensional LBM codes has not been examined in this manner for elliptical cylinders of different aspect ratios.

In this context, the present study develops a two-dimensional LBM solver and evaluates its performance for the flow past cylinders with aspect ratios between 0.50 and 2.00 at Re = 200. The solver is first

verified through grid and domain independence tests and validated against established benchmark data for the circular cylinder. It is then used to quantify the effect of the aspect ratio on the mean drag coefficient, the RMS lift coefficient, the Strouhal number, the ratio of lift fluctuation to drag, the vortex formation length and the spatial distribution of the wake fluctuation energy. The remainder of the paper is organised as follows, the numerical method and computational set-up are described in the next section, the results are presented and discussed thereafter, and the main conclusions are summarised in the final section.

MATERIALS AND METHODS

Lattice Boltzmann formulation

The flow is modelled with a two-dimensional in-house solver based on the Lattice Boltzmann equation with the single-relaxation-time Bhatnagar-Gross-Krook (BGK) collision operator and the standard D2Q9 velocity set (Krüger et al., 2017). The evolution of the particle distribution functions f_i is expressed as

$$f_i(\mathbf{x} + \mathbf{c}_i \Delta t,\ t + \Delta t) - f_i(\mathbf{x}, t) = -\frac{1}{\tau}\left[f_i(\mathbf{x}, t) - f_i^{\mathrm{eq}}(\mathbf{x}, t)\right] \qquad (1)$$

where $\mathbf{c}_i$ are the discrete lattice velocities, Δt is the time step and τ is the dimensionless relaxation time. The equilibrium distribution is given by the second-order expansion of the Maxwell-Boltzmann distribution,

$$f_i^{\mathrm{eq}} = w_i \rho \left[1 + \frac{\mathbf{c}_i \cdot \mathbf{u}}{c_s^2} + \frac{(\mathbf{c}_i \cdot \mathbf{u})^2}{2c_s^4} - \frac{\mathbf{u} \cdot \mathbf{u}}{2c_s^2}\right] \qquad (2)$$

in which the weighting factors are $w_0 = 4/9$ for the rest particle, $w_{1\ldots4} = 1/9$ for the axial directions and $w_{5\ldots8} = 1/36$ for the diagonal directions, and $c_s = 1/\sqrt{3}$ is the lattice speed of sound. The macroscopic density and momentum are obtained from the moments of the distribution functions,

$$\rho = \sum_{i=0}^{8} f_i\,, \qquad \rho\mathbf{u} = \sum_{i=0}^{8} f_i\ \mathbf{c}_i \qquad (3)$$

and the kinematic viscosity is related to the relaxation time through

$$\nu = c_s^2 \left(\tau - \frac{1}{2}\right) \Delta t \qquad (4)$$

Through the Chapman-Enskog expansion, this scheme recovers the incompressible Navier-Stokes equations in the low Mach number limit (Krüger et al., 2017). Each time step consists of a local collision at the fluid nodes followed by a pull-type streaming step to the neighbouring nodes. The solver is written in Python, and the collision and streaming kernels are compiled just-in-time with Numba and parallelised over the lattice rows, while a vectorised NumPy implementation of the same operations is retained as a fallback.

Geometry, computational domain and boundary conditions

The investigated bodies are elliptical cylinders whose transverse (cross-flow) dimension D is kept constant, while the streamwise dimension is varied. The aspect ratio is defined as the ratio of the streamwise length to the cross-flow width, so that the transverse and streamwise semi-axes are $b = D/2$ and $a = AR \cdot D/2$, respectively. A lattice node is flagged as solid when its polar coordinates (r, θ) relative to the body centre satisfy

$$r \le R(\theta) = \frac{ab}{\sqrt{(b\cos\theta)^2 + (a\sin\theta)^2}} \quad (5)$$

Accordingly, $AR < 1$ corresponds to blunt bodies compressed in the streamwise direction, $AR = 1$ to the circular cylinder and $AR > 1$ to slender, streamlined bodies. Five cases are considered, namely $AR =$ 0.50, 0.75, 1.00, 1.33 and 2.00, which are listed as Case 1 to Case 5 in Table 4. Since D is the frontal width for every case, the blockage ratio remains identical, and Re and all force coefficients share the same reference length, which allows a direct comparison between the configurations.

The rectangular computational domain extends $32D$ in the streamwise direction and $16D$ in the transverse direction, which corresponds to a lattice of 1600 × 800 nodes for the selected resolution. The body centre is placed $8D$ downstream of the inlet and on the domain centreline, providing a wake region of $24D$ and a blockage ratio of $D/H = 6.25\%$. At the inlet, the populations are set to the equilibrium distribution of Eq. (2) with $\rho = 1$ and a uniform velocity U_∞. To limit the initial pressure waves, the inlet velocity is increased from zero following a cosine ramp over the first 2000 time steps, and during this ramp a small transverse velocity component equal to 5% of the instantaneous inlet velocity is superimposed to break the flow symmetry and trigger vortex shedding. At the outlet, a pressure

boundary condition based on the anti-bounce-back scheme is imposed, in which the unknown incoming populations are reconstructed as

$$f_{\bar{\imath}}(\mathbf{x}_b) = -f_i(\mathbf{x}_b) + 2w_i\rho_0\left[1 + \frac{(\mathbf{c}_i\cdot\mathbf{u}_b)^2}{2c_s^4} - \frac{\mathbf{u}_b\cdot\mathbf{u}_b}{2c_s^2}\right] \qquad (6)$$

where $\bar{\imath}$ denotes the direction opposite to i, $\rho_0 = 1$ is the prescribed outlet density and $\mathbf{u}_b$ is the velocity at the adjacent interior node. Prescribing the outlet pressure in this way allows the flow rate to adjust freely, so that global mass conservation is maintained without artificial density corrections. Free-slip conditions are applied on the lateral boundaries through the specular reflection of the populations. The no-slip condition on the body is enforced with the full-way bounce-back scheme, in which no collision is performed at the solid nodes and the populations streaming into them are reflected in the opposite direction. The hydrodynamic forces are evaluated at every time step with the momentum exchange method, by summing the momentum carried by the populations reflected at the solid nodes.

Flow parameters and post-processing

The Reynolds number based on the cross-flow width, $Re = U_\infty D/\nu$, is fixed at 200 for all cases. With $D = 50$ lattice units, $U_\infty = 0.08$ and $\nu = 0.02$ in lattice units, Eq. (4) gives $\tau = 0.56$, and the corresponding Mach number, $Ma = U_\infty/c_s \approx 0.14$, remains well below the limit commonly accepted for weakly compressible LBM simulations. The flow is initialised at rest with $\rho = 1$. The drag and lift coefficients and the Strouhal number are defined as

$$C_d = \frac{F_x}{1/2\rho U_\infty^2 D}, \qquad C_l = \frac{F_y}{1/2\rho U_\infty^2 D}, \qquad St = \frac{fD}{U_\infty} \qquad (7)$$

where F_x and F_y are the streamwise and transverse force components per unit span and f is the dominant vortex shedding frequency. Rather than prescribing an arbitrary number of iterations, the simulation length is derived from the physical time scales of the problem. The first 50,000 time steps, corresponding to 2.5 domain flow-through times (N_x/U_∞), are discarded as the initial transient. Statistics are then collected over a further 93,750 time steps, which corresponds to approximately 30 vortex shedding periods, giving a total of 143,750 time steps per case. The mean drag coefficient $\overline{C_d}$ and the RMS lift coefficient $C_{l,\mathrm{rms}}$ are computed over this window, and f is obtained from the Hann-windowed fast Fourier transform of the lift signal, with parabolic interpolation around the spectral peak to refine the frequency estimate. To confirm that the statistics are not affected by a slowly developing drift, the window is divided into five equal segments, and the ratio of $C_{l,\mathrm{rms}}$ in the last segment to that in the second segment is required to lie between 0.85 and 1.18. The ratio $C_{l,\mathrm{rms}}/\overline{C_d}$ is adopted as a measure of the transverse force fluctuation obtained per unit mean drag, which is relevant for flow-induced vibration and energy harvesting applications.

The wake topology is characterised through the velocity field averaged over the same statistics window. The vortex formation length L_f is measured along the wake centreline from the rear stagnation point of the body ($x = x_c + a$) to the first location where the mean streamwise velocity becomes non-negative, i.e. the downstream end of the mean recirculation region. In addition, up to 350 velocity snapshots, equally spaced over the statistics window (about 11 snapshots per shedding cycle), are stored in a wake region extending from $1.5D$ upstream to $15D$ downstream of the body centre and $\pm 4D$ in the transverse direction. From these snapshots, the wake fluctuation energy is computed as $WFE = 1/2\left(\overline{u'^2} + \overline{v'^2}\right)/U_\infty^2$, where u' and v' are the fluctuating velocity components, and its spatial distribution is used to locate the regions of intense unsteadiness in the near wake. Instantaneous vorticity is presented in the normalised form $\omega_z D/U_\infty$.

Grid and domain independence

The sensitivity of the solution to the lattice resolution was examined for the circular cylinder using 25, 50 and 100 lattice nodes per diameter, with the finest resolution taken as the reference (Table 1). Increasing the resolution from 50 to 100 nodes changes $\overline{C_d}$, $C_{l,\mathrm{rms}}$ and St by 1.2%, 3.3% and 0.1%, respectively, whereas the coarsest lattice yields deviations of up to 8.9%. Accordingly, a resolution of 50 nodes per diameter was selected as a reasonable compromise between accuracy and computational cost. The influence of the domain size was then assessed with domains of $20D \times 10D$, $32D \times 16D$ and $48D \times 24D$ (Table 2). Relative to the largest domain, the $32D \times 16D$ domain differs by 2.0%, 3.5% and 1.0% in $\overline{C_d}$, $C_{l,\mathrm{rms}}$ and St, respectively, while the smallest domain produces deviations exceeding

11% in $C_{l,\mathrm{rms}}$, which is likely attributable to stronger confinement effects. The $32D \times 16D$ domain was therefore adopted for all subsequent simulations. The validation of the selected configuration against benchmark data for the circular cylinder (Henderson, 1997; Williamson, 1989; Rajani et al., 2009; Hu et al., 2014; Celik and Kiziloglu, 2026) is presented in the following section. In Tables 1 to 3, the relative deviation is defined as $\varepsilon = |\varphi - \varphi_{\mathrm{ref}}|/\varphi_{\mathrm{ref}} \times 100$, where φ_{ref} is the value obtained on the finest lattice (Table 1), on the largest domain (Table 2), or reported in the literature (Table 3).

FINDINGS AND DISCUSSION

The independence studies were conducted, and then the developed solver was validated against benchmark data reported for the flow past a circular cylinder at Re = 200. The mean drag coefficient, the RMS lift coefficient, and the Strouhal number obtained in the present study are compared with the results of Henderson (1997), Williamson (1989), Hu et al. (2014), Rajani et al. (2009), and Celik and Kiziloglu (2026), as shown in Table 3.

The present solver predicts a mean drag coefficient of 1.3752, which deviates from the reference values by between 1.35% and 3.17%. Similarly, the Strouhal number of 0.2011 is in close agreement with the literature, and the corresponding deviations range from 2.08% to 3.12%. As the maximum relative deviation obtained for these two parameters is below 3.2%, the present solver is considered sufficiently accurate to capture both the mean drag and the shedding frequency. Furthermore, the RMS lift coefficient of the present study is 0.4860, which falls between the values of Rajani et al. (2009) and Hu et al. (2014), and is only 1.99% higher than that of Celik and Kiziloglu (2026). In addition, the mean wake topology was compared with the reference data of Celik and Kiziloglu (2026), as shown in Figure 1. The mean streamwise velocity field and the extent of the recirculation region are reproduced with good fidelity by the present numerical approach. The non-dimensional vortex formation length (L_f/D) is predicted as 0.86, which is approximately 1% lower than the reference value of 0.87. The results indicate that the present numerical solver is able to resolve the near-wake structure and to predict the aerodynamic forces.

Table 3. Comparison of the present results with previous studies.

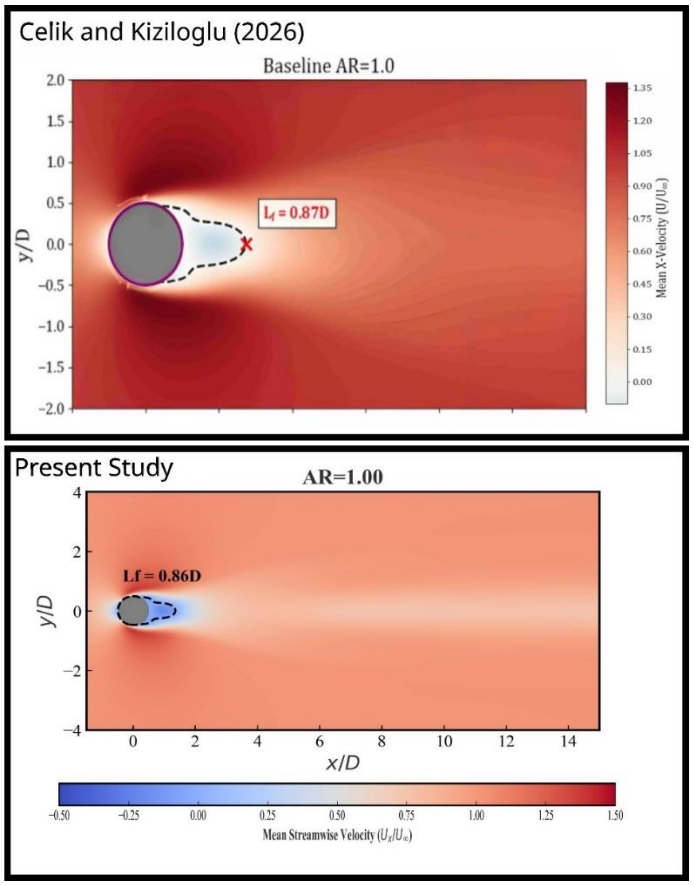

Figure 1. Mean streamwise velocity contours and vortex formation length for AR = 1.00, Celik and Kiziloglu (2026) (top) and the present study (bottom).

After completing the validation process, the effects of the aspect ratio on the aerodynamic forces and wake characteristics were systematically investigated for five configurations, with aspect ratios ranging from 0.50 to 2.00. The resulting aerodynamic force coefficients are summarised in Table 4 and illustrated in Figures 2 and 3.

Table 4. Computational results of the aerodynamic parameters for the different aspect ratios.

	□□	$\overline{□_□}$ [−]	□□□□ [−]	□□ [−]
Case 1	0.50	2.1015	0.6863	0.2097
Case 2	0.75	1.7045	0.6483	0.2141
Case 3	1.00	1.3752	0.4860	0.2011
Case 4	1.33	1.1431	0.3060	0.1935
Case 5	2.00	0.9543	0.1536	0.1959

The mean drag coefficient decreases monotonically with increasing aspect ratio, as shown in Figure 2. The maximum value of 2.1015 is obtained for an aspect ratio of 0.50, whereas the minimum mean drag coefficient of 0.9543 corresponds to an aspect ratio of 2.00. This trend is qualitatively consistent with those reported for elliptical cylinders at low Reynolds numbers (Thompson et al., 2014; Shi et al., 2020), although a direct quantitative comparison is not possible owing to differences in Reynolds number and blockage. The RMS lift coefficient in Figure 3 shows a similar trend, decreasing from 0.6863 at AR = 0.50 to 0.1536 at AR = 2.00. Higher aspect ratios lead to considerably lower force fluctuations, indicating a reduced vortex shedding intensity. The Strouhal number, however, follows a different trend from the mean drag and RMS lift coefficients. It reaches a maximum value of 0.2141 at AR = 0.75 and decreases to 0.1935 at AR = 1.33. For AR ≥ 1.33, the Strouhal number remains nearly unchanged, and the difference between the AR = 1.33 and AR = 2.00 cases is smaller than the raw spectral resolution ($\Delta St \approx 0.007$); this difference should therefore be interpreted with caution.

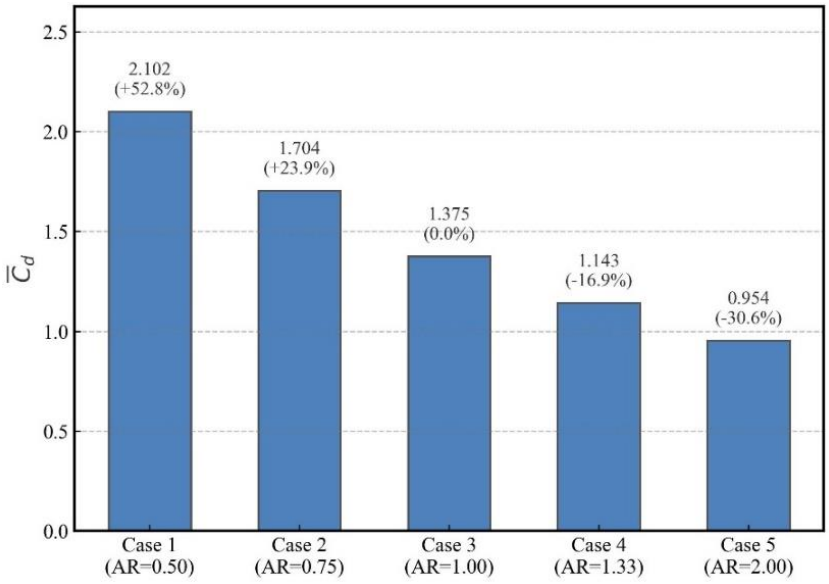

Figure 2. Mean drag coefficient across different aspect ratios.

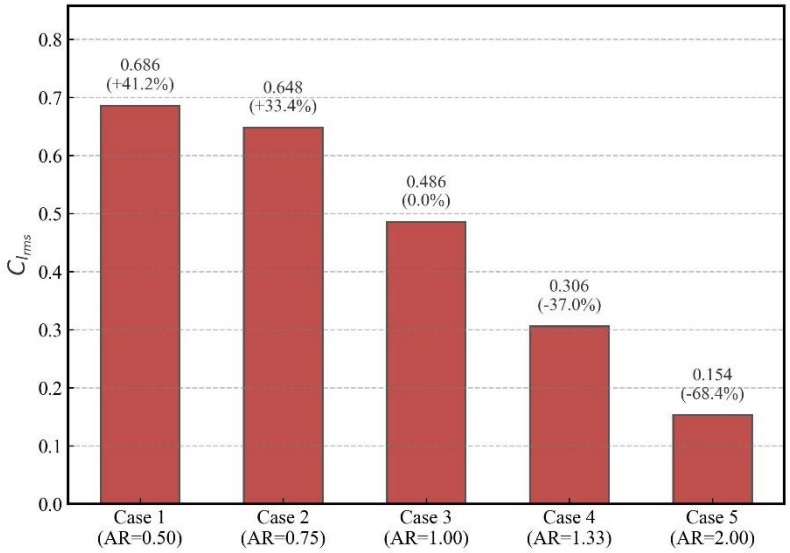

Figure 3. RMS lift coefficient across different aspect ratios.

The ratio of the RMS lift coefficient to the mean drag coefficient is presented in Figure 4. This ratio reaches its maximum value of 0.380 at AR = 0.75. For the more streamlined bodies with AR > 1, the ratio decreases rapidly, reaching 0.161 at AR = 2.00. The body with an aspect ratio of 0.50 generates the largest absolute lift fluctuation; however, it also experiences the highest mean drag among all cases. Accordingly, the AR = 0.75 case combines a strong fluctuating lift with a lower mean drag than the AR = 0.50 case.

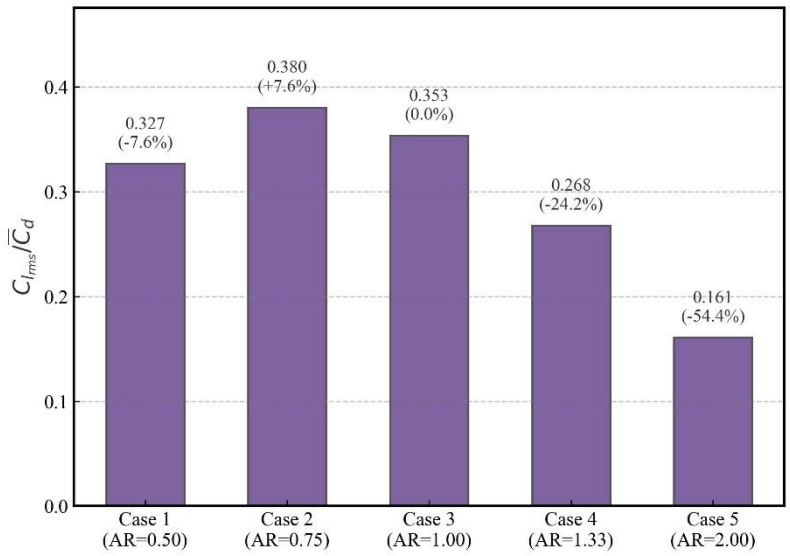

Figure 4. RMS lift coefficient to the mean drag coefficient ratio across different aspect ratios.

The spatial distribution of the wake fluctuation energy (WFE) is presented in Figure 5 for the configurations with aspect ratios of 1.00 and 0.75. For the baseline circular cylinder, the fluctuation energy peaks at about 0.24 in the near wake. The AR = 0.75 configuration shows a similar pattern, but the energy is concentrated closer to the body and its peak value is about 0.35, which is approximately 45% higher than that of the baseline case. In addition, the fluctuation energy remains higher than that of the baseline case along the wake. The more intense fluctuation energy of the AR = 0.75 body suggests a stronger and more rapid roll-up of the separated shear layers, in line with its higher RMS lift coefficient (Table 4).

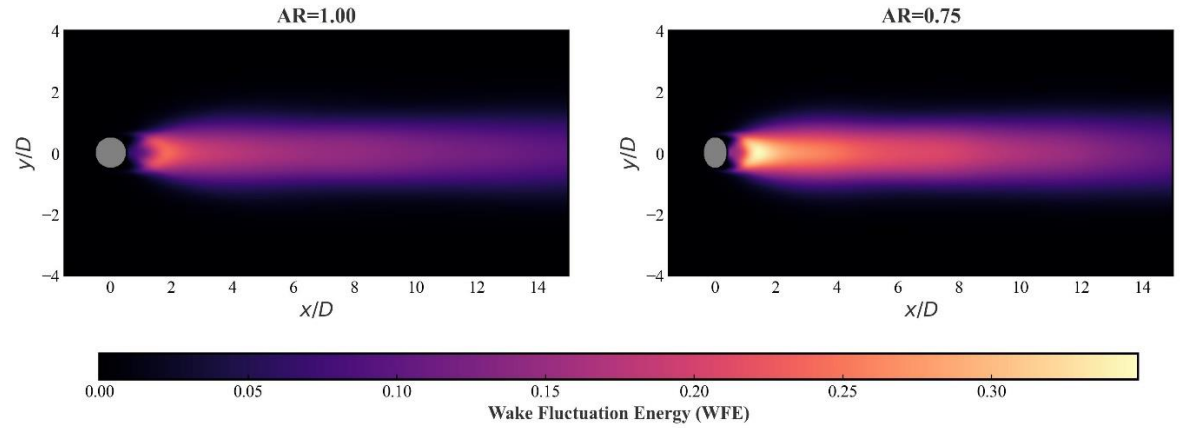

Figure 5. Spatial distribution of wake fluctuation energy for the cylinders with aspect ratios of 1.00 and 0.75.

The mean streamwise velocity contours and the corresponding vortex formation lengths are compared in Figure 6. The vortex formation length, L_f, is the length of the mean recirculation region behind the body. It is measured along the wake centreline from the rear of the body to the point where the mean streamwise velocity becomes zero and is shown by the dashed contour in Figure 6. For the baseline circular cylinder, the recirculation region extends to L_f = 0.86D. On the other hand, the recirculation region is shorter for the aspect ratio of 0.75, at 0.62D. As a result, the wake begins to recover towards the free-stream value closer to the body. The shorter formation length obtained for AR = 0.75 is consistent with both the amplified wake fluctuation energy shown in Figure 5 and the higher RMS lift coefficient reported in Table 4.

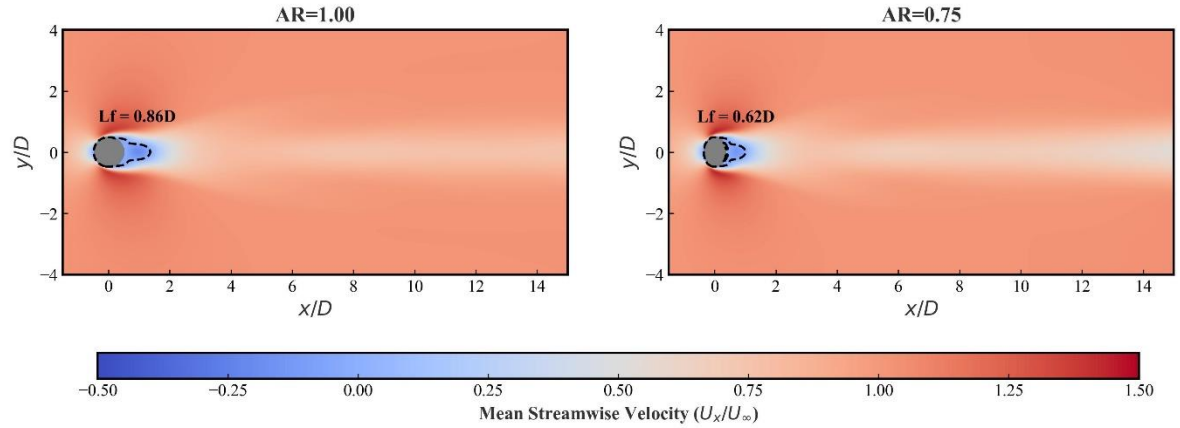

Figure 6. Mean streamwise velocity contours and vortex formation lengths for the cylinders with aspect ratios of 1.00 and 0.75.

The instantaneous normalised spanwise vorticity fields for the AR = 0.75 and AR = 1.00 configurations are compared in Figure 7. A fully developed von Kármán vortex street is observed for both cases. However, behind the AR = 0.75 cylinder, the shear layers roll up closer to the body, which leads to a denser vortex street. This behaviour corresponds to a higher Strouhal number of 0.214 for an aspect ratio of 0.75. These observations are supported by the wake fluctuation energy distribution shown in Figure 5 and by the mean flow topology presented in Figure 6.

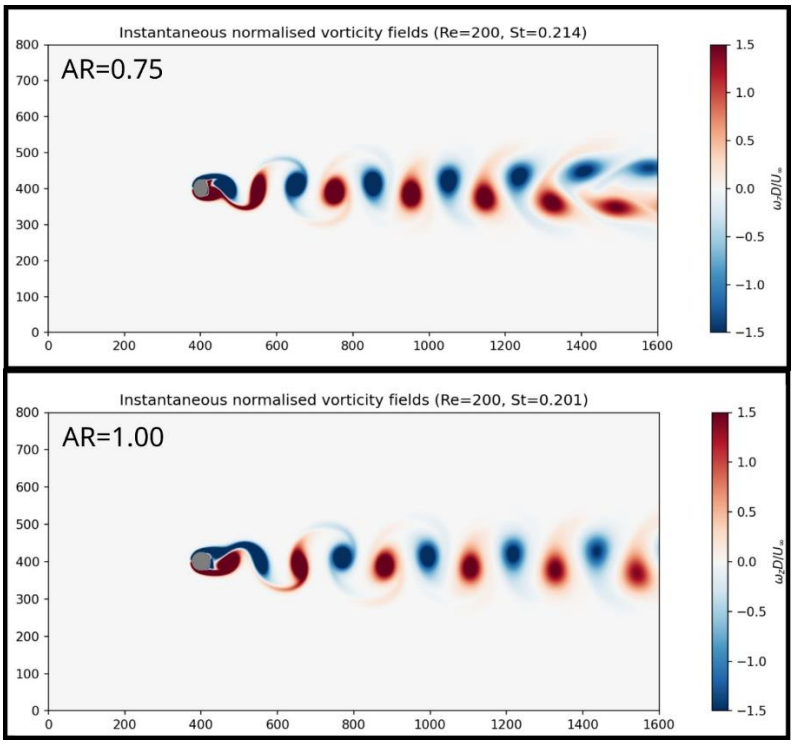

Figure 7. Instantaneous normalised spanwise vorticity fields for the cylinders with aspect ratios of 0.75 (top) and 1.00 (bottom) at Re = 200.

CONCLUSION AND RECOMMENDATIONS

A two-dimensional Lattice Boltzmann solver was developed and applied to the flow past cylinders with aspect ratios ranging from 0.50 to 2.00 at a Reynolds number of 200. The solver was verified through grid and domain independence studies and validated against benchmark data, with maximum deviations below 3.2% for the mean drag coefficient and the Strouhal number, and a predicted vortex formation length of 0.86D against the reference value of 0.87D. The mean drag and RMS lift coefficients decreased monotonically with increasing aspect ratio. The aspect ratio also affected the vortex shedding frequency, as the Strouhal number reached its maximum value of 0.2141 at an aspect ratio of 0.75, while it remained nearly unchanged (0.1935 and 0.1959) for the more streamlined bodies with AR ≥ 1.33.

The ratio of the RMS lift coefficient to the mean drag coefficient reached its highest value of 0.380 at an aspect ratio of 0.75. The wake analyses showed that this configuration shortened the vortex formation length from 0.86D to 0.62D. The shorter formation length was consistent with a shear-layer roll-up closer to the body and a more energetic vortex street.

These results are subject to some limitations. The simulations are two-dimensional, whereas three-dimensional wake instabilities are expected near Re = 200. The full-way bounce-back scheme represents the curved surface in a staircase manner, which is most restrictive for AR = 0.50, whose streamwise thickness spans only 25 lattice nodes. Future work will address interpolated or immersed boundary treatments, a wider Reynolds number range, and the coupling of the solver with a structural model to quantify the actual vortex-induced vibration response.

ABSTRACT
This study presents a numerical investigation of unsteady flow past a 30º inclined flat plate at a Reynolds number of 150,000. The simulations are carried out using the OpenFOAM 2406 computational fluid dynamics framework. The reliability of the numerical setup is established through systematic mesh and time-step independence tests. The aerodynamic behaviour of the baseline flat plate is validated against experimental and numerical data from the literature. Following the validation phase, a geometric modification is introduced by attaching a semicircular cylinder with a non-dimensional diameter (d^*) of 0.14 to the lower surface of the plate. This modification is evaluated under three positional configurations. Results indicate that the time-averaged drag and lift coefficients remain virtually constant across all configurations, varying by less than 2%. On the other hand, the position of the passive element strongly governs the wake topology, the transition behaviour, and the aerodynamic force fluctuations. In the leading-edge configuration (V1), the modification has a negligible effect on the forces and the wake, and the flow remains essentially identical to the baseline plate. In the mid-chord configuration (V2), the element confines the recirculation region and stabilises the near wake. This leads to a rapid transition to the periodic regime and a 10.5% reduction in the root-mean-square lift fluctuations ($C_{L_{rms}}$). Thus, the V2 configuration is effective in suppressing vortex-induced vibrations (VIV). The trailing-edge configuration (V3) enhances the roll-up of the shear layer and produces larger, more energetic vortices. As a result, the root-mean-square lift fluctuations increase by 8.9% and the Strouhal number decreases to 0.335, which indicates a potential for flow-induced energy harvesting.

ÖZET
Bu çalışmada, Reynolds sayısının 150.000 olduğu koşulda 30° eğimli bir düz plaka etrafındaki zamana bağlı akış sayısal olarak incelenmiştir. Simülasyonlar, OpenFOAM 2406 hesaplamalı akışkanlar dinamiği yazılımı ile gerçekleştirilmiştir. Sayısal modelin güvenilirliği, sistematik ağ ve zaman adımı bağımsızlık testleri ile ortaya konmuştur. Referans düz plakanın aerodinamik davranışı, literatürdeki deneysel ve sayısal verilerle doğrulanmıştır. Doğrulama aşamasının ardından, plakanın alt yüzeyine boyutsuz çapı (d*) 0,14 olan yarım daire kesitli bir silindir eklenerek geometrik bir modifikasyon uygulanmıştır. Bu modifikasyon üç farklı konumda değerlendirilmiştir. Sonuçlar, zaman-ortalama sürükleme ve kaldırma katsayılarının tüm konfigürasyonlarda %2'den daha az değiştiğini göstermiştir. Buna karşın, pasif elemanın konumu art-iz topolojisini, rejim geçiş davranışını ve aerodinamik kuvvet dalgalanmalarını önemli ölçüde etkilemiştir. Hücum kenarı konfigürasyonunda (V1), modifikasyonun kuvvetler ve art-iz üzerindeki etkisi ihmal edilebilir düzeydedir ve akış, referans plakayla neredeyse özdeş kalmıştır. Orta bölge konfigürasyonunda (V2), resirkülasyon bölgesi yarım silindir tarafından sınırlandırılmış ve yakın art-izi kararlı hale gelmiştir. Bu durum, periyodik rejime hızlı bir geçişe ve kaldırma kuvveti dalgalanmasında %10,5 civarında bir azalmaya yol açmıştır. Dolayısıyla V2 konfigürasyonu, girdap kaynaklı titreşimlerin (VIV) bastırılmasında etkili bir rol oynamıştır. Firar kenarı konfigürasyonu (V3) ise kesme tabakasının yuvarlanmasını güçlendirmiş ve daha enerjik girdapların üretilmesine sebep olmuştur. Sonuç olarak, kaldırma kuvveti dalgalanması %8,9 oranında artmış ve Strouhal sayısı 0,335'e düşmüştür. Bu durum V3 modifikasyonunun akış kaynaklı enerji hasadı için bir potansiyele sahip olduğunu göstermiştir.

INTRODUCTION

The phenomenon of flow over bluff bodies involves complex vortex dynamics and wake structures. Vortex-induced vibrations (VIV) are triggered by flow separation from the sharp edges of bluff bodies and the von Kármán vortex street (Williamson, 1996). These vibrations are considered critical engineering problems that lead to fatigue loads on several systems such as bridges, heat exchangers, underwater pipes, and high buildings (Bearman, 1984). To mitigate these loads, VIV are commonly suppressed using passive bluff-body modifications such as splitter plates and control rods (Zhu and Yao, 2015; Law and Jaiman, 2017).

In recent years, however, vortex-induced vibrations have been recognised as a sustainable energy solution that can generate electricity for low-power sensors. The mechanical displacement caused by fluid flow is converted into useful electrical energy by employing piezoelectric patches or electromagnetic systems (Mehmood et al., 2013; Alhadidi and Daqaq, 2016). In this regard, vortex-induced vibrations are enhanced to maximise energy harvesting potential using bluff-body designs such as cross-sectional modifications and leeward surface protrusions (Sun et al., 2019; Xing et al., 2024). For instance, Lei and Sun (2023a) added a splitter plate with a tuned afterbody length to a semicircular wall. This modification caused the wake to evolve from VIV to galloping. In a later study, Lei and Sun (2023b) placed upstream bluff bodies ahead of the wall to achieve the same transition.

The inclined flat plate is another widely studied bluff-body geometry. It is a fundamental case for investigating fully separated flows (Fage and Johansen, 1927), since separation is fixed at the sharp edges of the plate, making the wake largely insensitive to the Reynolds number (Re) (Chen and Fang, 1996). First, Fage and Johansen (1927) experimentally investigated the flow over an inclined flat plate and reported the pressure distribution and wake characteristics at various inclination angles. They concluded that the vortex shedding frequency increased as the inclination angle decreased. In addition, vortex production was identical at both sharp edges. Chen and Fang (1996) evaluated the Strouhal number of a flat plate with bevelled sharp edges. The experiments were performed at angles of attack (α) from 0° to 90° and Reynolds numbers from 3.5×10^3 to 3.2×10^4. Their results showed that the Reynolds number has no significant effect on the Strouhal number in the fully separated regime (α = 10°–90°), while its influence becomes significant at low incidence due to flow reattachment. Shademan and Naghib-Lahouti (2020) investigated an inclined flat plate using large-eddy simulation (LES) to provide a detailed description of the wake structure. The inclined flat plate is further investigated for flow-induced energy harvesting, as the sharp edges produce a stable and predictable wake. The plate frequently acts as the main oscillating body, extracting energy through flutter (Olivieri et al., 2017). Alternatively, the geometry serves as an auxiliary element that generates or modifies the wake to enhance the performance of a downstream harvester (Liu et al., 2020).

In this study, a flat plate with an inclination angle of 30° is investigated using a Computational Fluid Dynamics (CFD) approach. The main objective is to evaluate the energy harvesting potential of the plate by attaching a semicircular cylinder to the lower surface of the plate. The semicircular cylinder is therefore positioned at the leading edge, the mid-chord, and the trailing edge, and the corresponding effects on the aerodynamic forces, shedding frequency, and wake structure are investigated.

MATERIALS AND METHODS

The numerical simulations were performed using the open-source CFD software OpenFOAM v2406. The geometry was a sharp-edged inclined flat plate at an inclination angle of 30°, with a chord length of $c = 0.15$ m and a thickness of 3% of the chord. The two-dimensional computational domain was rectangular, with an upstream length of 8c and a downstream length of 20c. The upper and lower boundaries of the domain were located 15c from the plate, as shown in Figure 1. All outer boundaries of the computational domain were assigned the freestream condition, enforcing the free-stream value on inflow and a zero-gradient condition on outflow (OpenCFD Ltd., 2024). The free-stream velocity was set to $U_\infty = 15$ m/s, and the kinematic viscosity was $\nu = 1.5 \times 10^{-5}$ m²/s, corresponding to a chord-based Reynolds number of 1.5×10^5, consistent with the reference studies used for validation. A no-slip boundary condition was applied on the plate surface.

The fluid flow was considered two-dimensional, incompressible and unsteady state. For turbulence modelling, SST k-ω was employed. Pressure-velocity coupling was achieved using the PIMPLE algorithm, which combines the PISO (Pressure Implicit with Splitting of Operators) and SIMPLE (Semi-Implicit Method for Pressure-Linked Equations) algorithms. A constant time step verified through a

time-step independence study, was employed to ensure that the Courant number remained below unity ($Co \leq 1$) in each simulation.

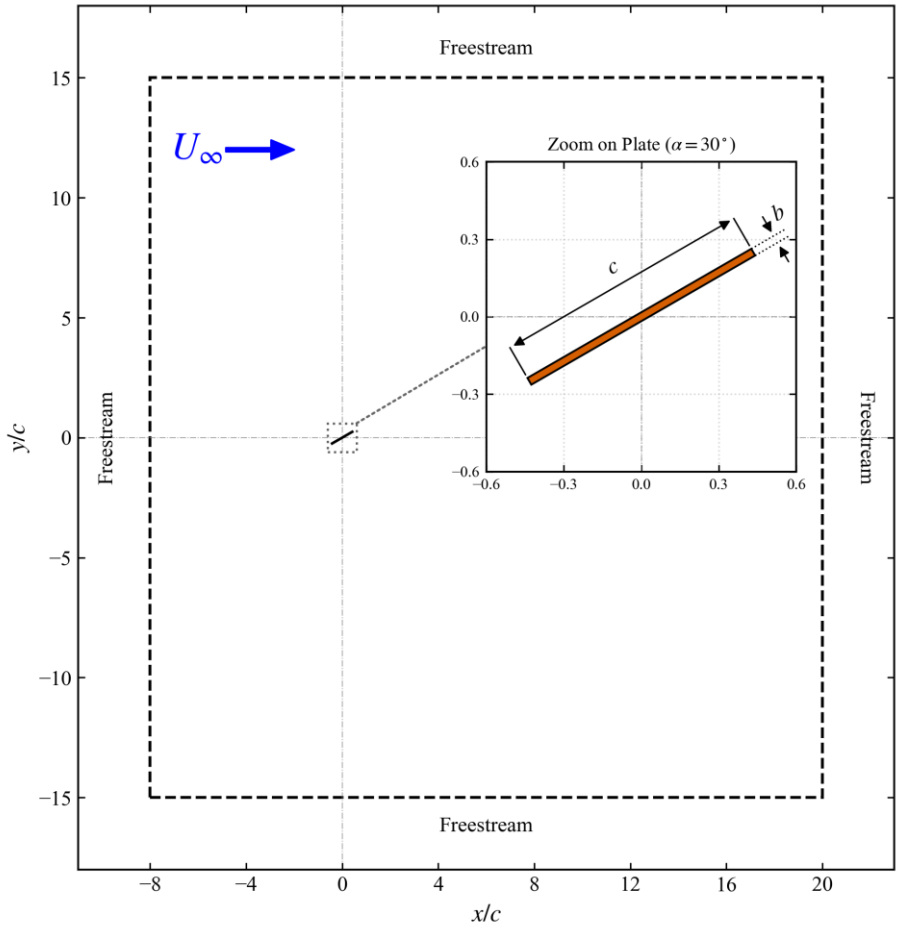

Figure 1. Computational domain and boundary conditions.

Following the numerical setup, the mesh independence and time-step independence tests were performed. Four grids of varying resolution, with the number of elements ranging from 55,000 to 460,000, were generated using SALOME (version 9.15.0) to evaluate the sensitivity of the results to mesh refinement. Furthermore, the time step independence tests were conducted considering time-step sizes of 2×10^{-5} s, 1×10^{-5} s, 5×10^{-6} s and 2×10^{-6} s. The results of the independence analysis are presented in the Findings and Discussion section.

Based on the Strouhal number of approximately 0.307 reported for a 30° inclined plate in the literature (Fage and Johansen, 1927), the shedding frequency for the present flow conditions was estimated to be approximately 30 Hz. This corresponds to a shedding period of about 0.033 s, so that the 1.0 s simulated period covers roughly 30 vortex-shedding cycles. In previous numerical studies of bluff-body wakes, the flow is reported to reach a statistically steady state after approximately ten shedding cycles (Kumar Pant et al., 2026). The simulation period adopted here is therefore about three times longer, which ensured that the initial transient had fully decayed and that the statistics were converged. Accordingly, the time-averaged drag and lift coefficients and the corresponding RMS values were computed from 0.40 s onwards.

The mesh and time-step independence studies were performed for the baseline plate, and the selected mesh and time step were subsequently applied to all modified configurations to ensure a consistent basis for comparison. A semicircular cylinder with a non-dimensional diameter of d* = d/c = 0.14 was attached to the lower surface of the plate. Three positions of the cylinder were considered, which are tangent to the leading edge (V1), at the mid-chord (V2), and tangent to the trailing edge (V3), as shown in Figure 2.

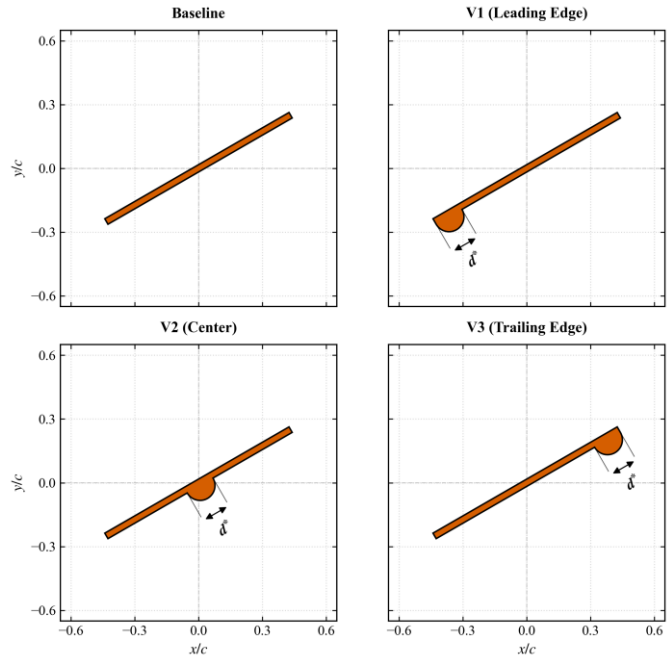

Figure 2. Schematic of the baseline plate and the three positions of the semicircular cylinder.

FINDINGS AND DISCUSSION

In this section, the numerical setup is first verified through mesh and time-step independence studies and validated against experimental and numerical data from the literature. Second, the influence of the semicircular cylinder position on the aerodynamic loads and wake structure is discussed.

The mesh independence tests were conducted to assess the sensitivity of the numerical results to the grid, as mentioned in the previous section. Mesh structures with different numbers of elements were evaluated in terms of the time-averaged drag and lift coefficients, as shown in Figure 3. The time-averaged drag coefficient is in the range of 0.858 to 0.898. The magnitude of the time-averaged lift coefficient increases gradually from 1.342 to 1.401. The differences between M3 (253×10³ cells) and M4 (460×10³ cells) are 0.12% for $\bar{C}_D$ and 0.5% for $|\bar{C}_L|$. The results indicate that further grid refinement has a negligible effect on the aerodynamic loads. As a result, M3 was selected, for the simulations to ensure accuracy at a reasonable computational cost. The grid structure of M3 is shown in Figure 4.

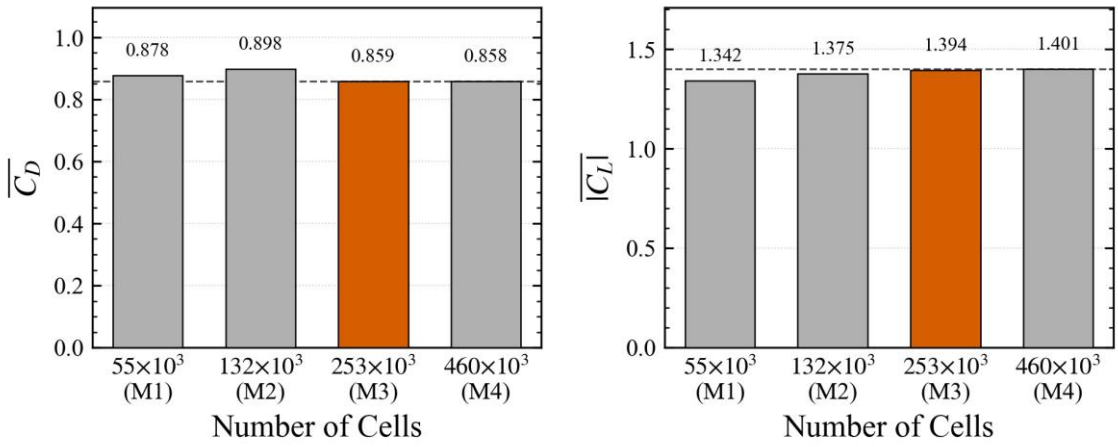

Figure 3. Mesh independence test results.

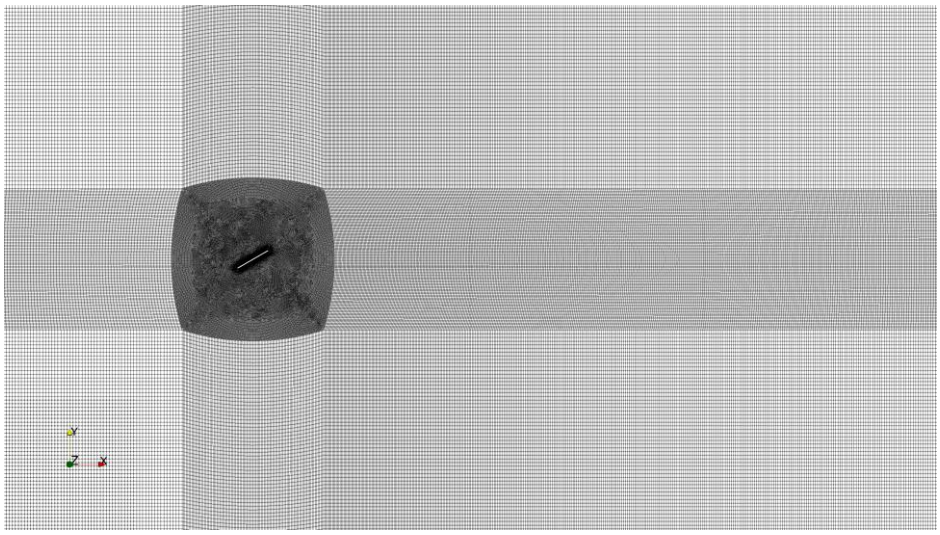

Figure 4. Computational grid used in the simulations.

The time-step independence tests were conducted using four time-step sizes, and the results are presented in Figure 5. Both the time-averaged drag and lift coefficients increase as the time step is reduced. A time-step size of 5×10^{-6} s was adopted, since the variation between Δt_3 and Δt_4 is less than 2% for both coefficients. This temporal resolution is considered sufficient to accurately capture the unsteady flow dynamics and wake characteristics behind the inclined plate.

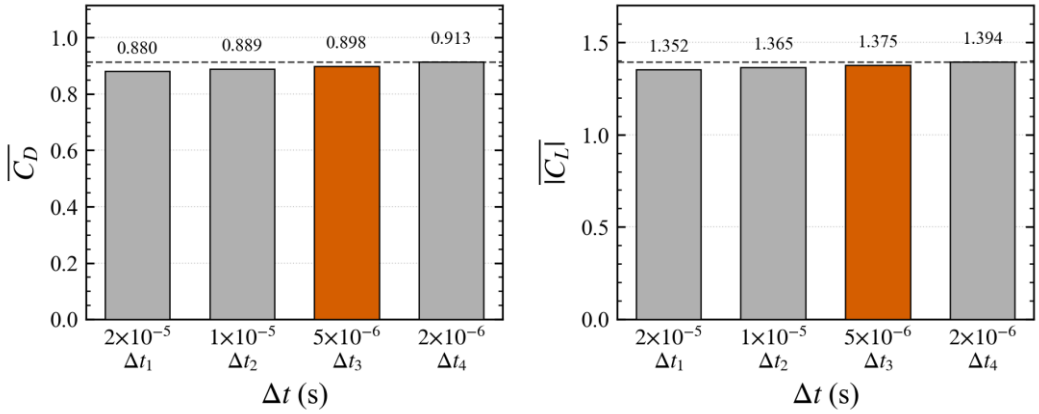

Figure 5. Time-step independence test results.

After the independence studies, the numerical setup was validated against the experimental data of Fage and Johansen (1927) and the Large Eddy Simulation (LES) results of Shademan and Naghib-Lahouti (2020). Figure 6 shows the time-averaged pressure coefficient distribution along the upper surface, where C_p decreases from about 1.0 at the leading edge towards the trailing edge, and along the lower surface, which exhibits a nearly uniform negative C_p plateau. The present results show excellent agreement with the experimental data throughout the upper surface. On the other hand, the present numerical model predicts slightly higher-pressure coefficients than the LES. On the lower surface, a nearly uniform pressure plateau is observed for both the results of the present study and the literature. However, the results indicate that pressure coefficients on the lower surface of the plate from the present study are considerably lower compared to the literature. This overprediction of the suction on the lower surface is a known limitation of two-dimensional simulations, in which the absence of spanwise vortex stretching leads to stronger and more coherent vortices in the near wake.

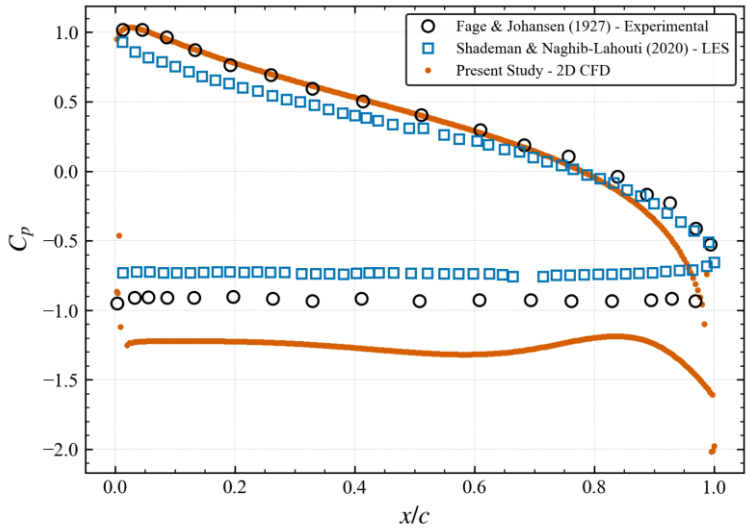

Figure 6. Validation of the time-averaged pressure coefficient along the plate.

The time-averaged drag and lift coefficients, the RMS lift coefficient and the Strouhal number of the baseline plate and the three configurations are given in Table 1. The mean force coefficients are almost unaffected by the position of the semicircular cylinder. Both the mean drag and the mean absolute lift coefficients change by less than 2% in all configurations. On the other hand, the RMS lift coefficient is highly influenced by the position of the element. In the V2 configuration, the RMS lift coefficient decreases by 10.5%, while an increase of 8.9% is observed for the V3 case.

Table 1. Aerodynamic coefficients of the baseline plate and the three configurations.

Case	$\overline{C_D}$ [−]	$\overline{\lvert C_L \rvert}$ [−]	$C_{L_{rms}}$ [−]	St [−]	$C_{L_{rms}}$ ϵ [%]
Base	0.8588	1.3937	0.1792	0.344	-
V1	0.8537	1.4056	0.1781	0.347	-0.6
V2	0.8418	1.3928	0.1604	0.350	-10.5
V3	0.8668	1.3928	0.1952	0.335	+8.9

The time-averaged streamlines are presented in Figure 7 to gain a better understanding of the flow characteristics around the plate. The flow separation is observed at the sharp leading edge and a large recirculation region is created on the lower side of the plate for all configurations. The recirculation region and the secondary vortex of V1 are almost identical to those of the baseline plate. In the V2 and V3 configurations, the streamline pattern inside the recirculation region differs from that of the baseline plate, whereas the secondary vortex remains at almost the same position. The overall mean flow topology is therefore preserved, which is consistent with the small changes in the mean loads given in Table 1.

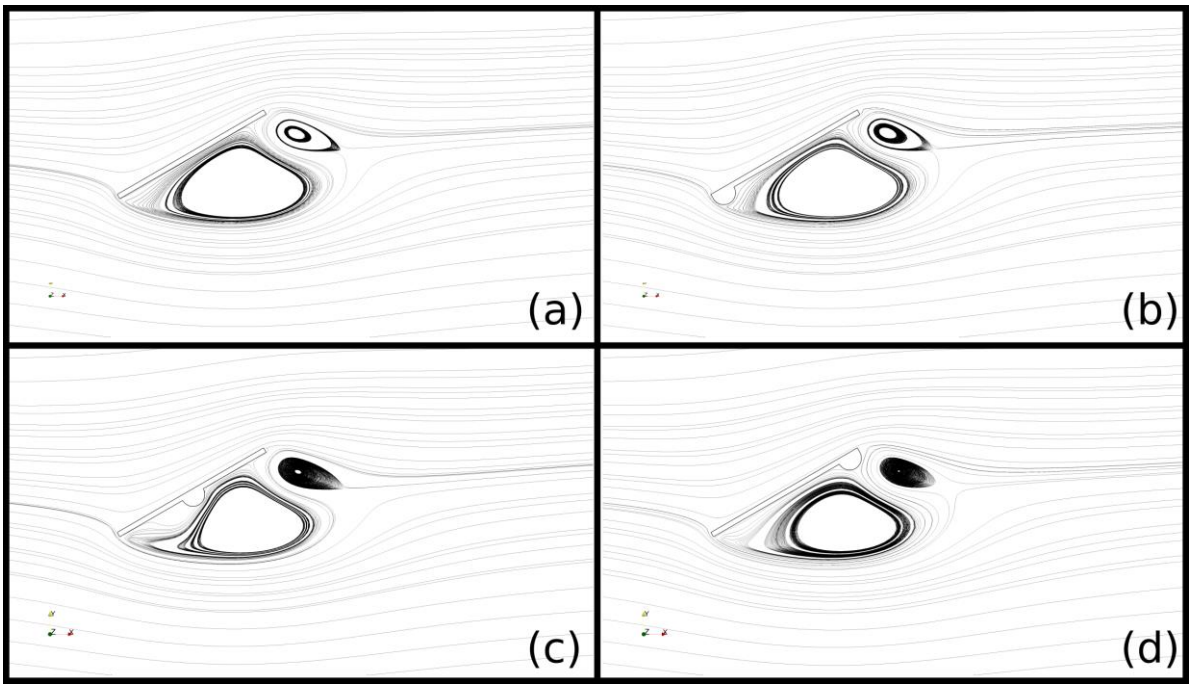

Figure 7. Time-averaged streamlines (a) Base, (b) V1, (c) V2, (d) V3.

Figure 8 shows the time history of the lift coefficient, which is negative in the adopted coordinate system. For this reason, the mean lift is given as an absolute value in Table 1. The baseline plate and V1 produce similar signals. On the other hand, the periodic regime rapidly becomes stable, and the amplitude of the lift coefficient is lower in the V2 configuration. Moreover, the lift coefficient signal remains irregular until flow time 0.30 s and the amplitude in the periodic regime is higher than in the other cases for the V3 case. These observations agree with the RMS lift coefficient values in Table 1.

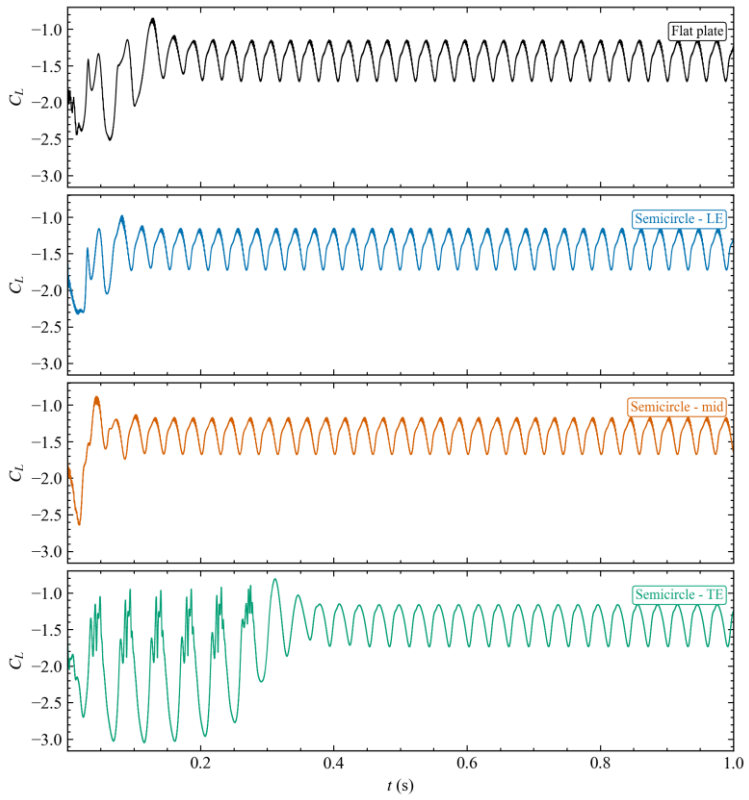

Figure 8. Time histories of the lift coefficient.

Figure 9 compares the vorticity fields at a flow time of 0.20 s. The wakes of the baseline plate and V1 have already formed a regular vortex street and are very similar to each other. The wake of V2 has also reached periodic shedding and has the most uniform vortex spacing. In contrast, the wake of V3 remains irregular and asymmetric. Moreover, periodic vortex shedding is observed for all configurations when the flow time reaches 1 s, as shown in Figure 10. Similar to the case at a flow time of 0.2 s, the wake of V1 is identical to that of the baseline plate at 1 s. On the other hand, the vortices behind the V2 plate have a more compact form near the body. In addition, a longer shear layer rolls up into a larger vortex close to the body in the V3 configuration. The differences are confined to the near wake, and the vortex spacing in the far wake is nearly identical in all cases.

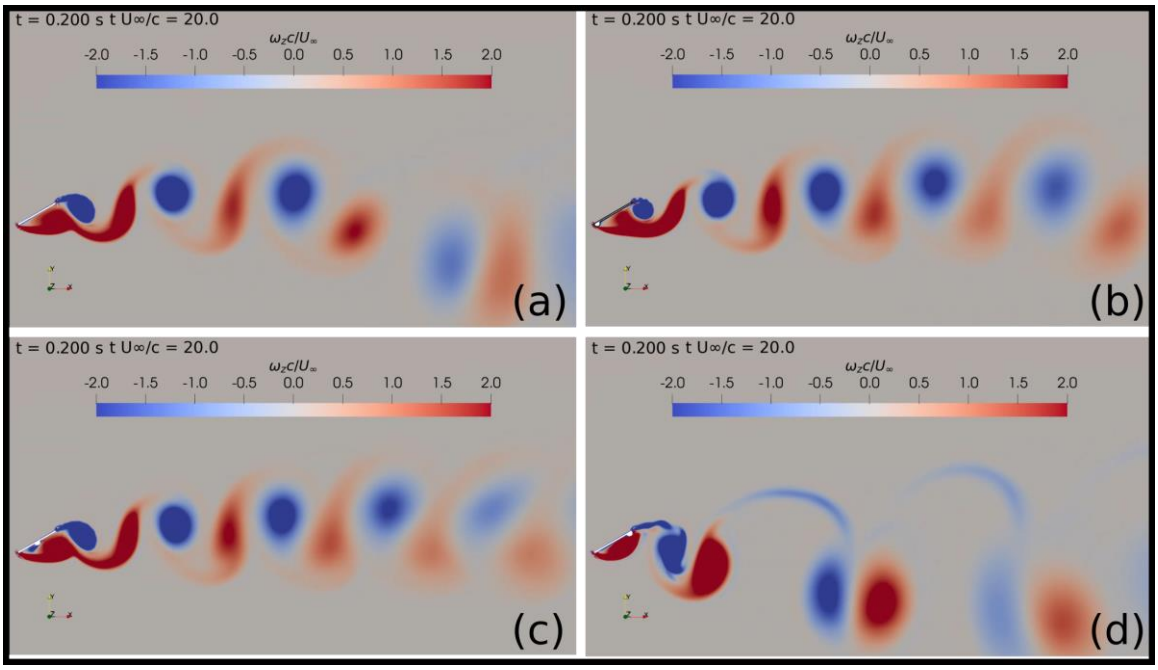

Figure 9. Instantaneous vorticity at a flow time of 0.20 s: (a) Base, (b) V1, (c) V2 and (d) V3.

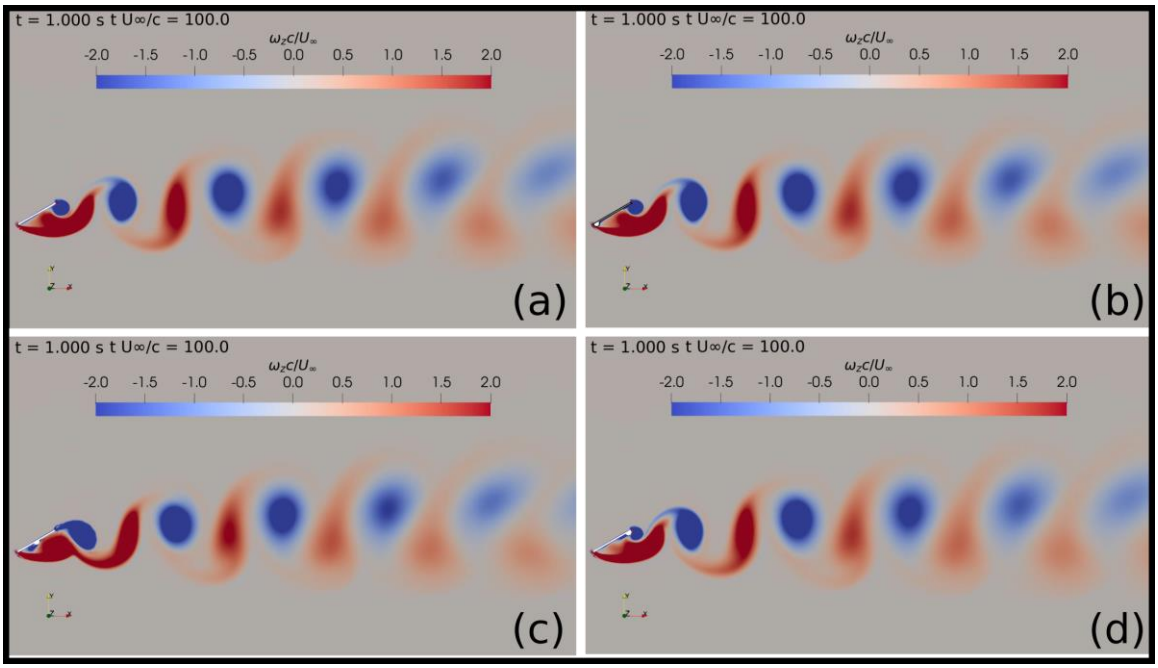

Figure 10. Instantaneous vorticity at a flow time of 1.0 s: (a) Base, (b) V1, (c) V2 and (d) V3.

CONCLUSION AND RECOMMENDATIONS

In this study, the unsteady flow around a 30° inclined flat plate at a Reynolds number of 1.5×10^5 was numerically investigated. The effect of the position of a semicircular cylinder attached to the lower surface of the plate was evaluated. The position of the element changed the lift fluctuations. However, the mean aerodynamic forces varied by less than 2% in all configurations. First, the element was placed at the leading edge (V1) and the forces, and the wake region remained almost the same as those of the flat plate. In the V2 case, the near wake was stabilised, the periodic regime was reached earlier and the RMS lift coefficient decreased by 10.5%. This configuration is therefore a promising solution for suppressing vortex-induced vibrations. At the trailing edge (V3), the RMS lift coefficient increased by 8.9% and larger vortices formed in the near wake at a slightly lower Strouhal number. The stronger lift fluctuation provides a larger excitation for a flexible structure, which indicates a potential for enhancing flow-induced energy harvesting.

Future work should include three-dimensional effects and a coupled fluid–structure interaction model to quantify the vibration response and to analyse energy harvesting potential.

Abstract
Machining processes provide high dimensional accuracy and surface quality in industrial manufacturing; however, they also generate considerable amounts of metallic chips. The efficient recovery of chips originating from economically valuable metals and alloys such as aluminum and bronze is important for reducing raw material consumption and developing sustainable manufacturing processes. Conventional metal recycling methods are largely based on remelting and may involve disadvantages such as high energy consumption, oxidation-related material losses, and the need for additional processing steps. For this reason, solid-state recycling methods based on the direct reshaping of metallic chips without melting have attracted increasing attention as an alternative approach.
In this study, the direct recycling of waste aluminum and CuSn10 bronze chips generated during machining processes by hot extrusion and their feasibility for composite material production will be investigated. Prior to processing, cleaning procedures will be applied to remove oil, dirt, and machining residues from the chip surfaces. The chips will then be dimensionally classified in order to evaluate the effect of different particle sizes on consolidation behavior. The prepared aluminum and CuSn10 bronze chips will be homogenized at different mixing ratios and subjected to hot extrusion at approximately 400–425 °C under pressures of about 270–300 MPa. The high plastic deformation imposed during extrusion is expected to enhance inter-chip contact and promote the formation of metallic bonding between the consolidated particles.
Various tests will be conducted to determine the physical and mechanical integrity of the produced samples. The effects of chip size, mixing ratio, and extrusion parameters on material integrity and mechanical behavior will be comparatively evaluated. The study aims to demonstrate the feasibility of converting waste Al and CuSn10 chips with different physical and mechanical characteristics into an integrated composite structure by hot extrusion without remelting, and to contribute to the development of a sustainable manufacturing approach for transforming metallic machining waste into value-added engineering materials.

Özet
Talaşlı imalat yöntemleri, endüstriyel üretimde yüksek boyutsal hassasiyet ve yüzey kalitesi sağlamasına karşın önemli miktarda metal talaşı oluşmasına neden olmaktadır. Özellikle alüminyum ve bronz gibi ekonomik değeri yüksek metal ve alaşımlardan oluşan talaşların etkin biçimde geri kazanılması, hammadde kullanımının azaltılması ve sürdürülebilir üretim süreçlerinin geliştirilmesi açısından önem taşımaktadır. Geleneksel metal geri dönüşüm yöntemleri büyük ölçüde ergitme esasına dayanmakta olup yüksek enerji tüketimi, oksidasyon kaynaklı malzeme kayıpları ve ilave işlem gereksinimleri gibi bazı dezavantajlara sahiptir. Bu nedenle, metal talaşlarının ergitilmeden doğrudan yeniden şekillendirilmesine dayanan katı hâlde geri dönüşüm yöntemleri alternatif bir yaklaşım olarak değerlendirilmektedir.
Bu çalışmada, talaşlı imalat işlemleri sonucunda ortaya çıkan atık alüminyum ve CuSn10 bronz talaşlarının sıcak ekstrüzyon yöntemi kullanılarak doğrudan geri dönüştürülmesi ve kompozit malzeme üretiminde kullanılabilirliğinin araştırılması amaçlanmaktadır. Üretim öncesinde talaş yüzeylerinde bulunabilecek yağ, kir ve işlem kalıntılarının giderilmesi amacıyla temizleme işlemleri uygulanacak, ardından talaşlar boyutsal olarak sınıflandırılarak farklı tane boyutlarının konsolidasyon davranışına etkisi değerlendirilecektir. Hazırlanan alüminyum ve CuSn10 talaşları farklı karışım oranlarında homojenleştirilecek ve yaklaşık 400–425 °C sıcaklık aralığında, 270–300 MPa seviyelerinde sıcak

ekstrüzyon işlemine tabi tutulacaktır. Ekstrüzyon sırasında uygulanan yüksek plastik deformasyon sayesinde talaşlar arasındaki temasın ve metalik bağ oluşumunun geliştirilmesi hedeflenmektedir. Üretilen numunelerin fiziksel ve mekanik bütünlüğünün belirlenmesi amacıyla farklı testler yapılacaktır. Elde edilen veriler kullanılarak talaş boyutu, karışım oranı ve ekstrüzyon parametrelerinin malzeme bütünlüğü ve mekanik davranış üzerindeki etkileri karşılaştırmalı olarak değerlendirilecektir. Çalışmanın sonucunda, farklı fiziksel ve mekanik özelliklere sahip atık Al ve CuSn10 talaşlarının ergitme işlemi uygulanmaksızın sıcak ekstrüzyonla bütüncül bir kompozit yapıya dönüştürülebilirliğinin ortaya konulması ve metal talaşlarının katma değerli mühendislik malzemelerine dönüştürülmesine yönelik sürdürülebilir bir üretim yaklaşımının geliştirilmesi hedeflenmektedir.

ABSTRACT

High-throughput nanoindentation generates load-displacement curves at scale, making manual anomaly screening impractical. This study tested whether sample-relative contextual descriptors improve prediction of expert-labelled anomalies in a post-acquisition batch setting. We analysed an open dataset of 9,600 curves from 150 electrodeposited NiFe thin-film samples; 3,409 curves (35.5%) were labelled anomalous in the revised annotations. Predictors comprised instrument-derived summary properties, hand-crafted curve-shape features describing loading, holding, unloading, and residual-depth behaviour, and sample-relative contextual descriptors computed from the other 63 curves without using anomaly labels. Logistic regression, random forest, and histogram gradient boosting were evaluated with fixed settings using five-fold sample-grouped cross-validation, with all 64 indentations from each sample kept in one fold. Balanced accuracy was the primary metric; results are mean ± SD across folds. Adding contextual descriptors increased mean balanced accuracy for all three model families, with random forest giving the highest mean value. For random forest, summary properties alone achieved 0.767 ± 0.011 balanced accuracy, curve-shape features 0.927 ± 0.017, and combined summary-plus-curve features 0.928 ± 0.015. Adding contextual descriptors increased balanced accuracy to 0.936 ± 0.013 and F1-score to 0.925 ± 0.013, with positive gains in all five grouped folds. Random curve-level validation using the same combined summary-plus-curve features without contextual descriptors gave a slightly higher estimate than sample-grouped validation (0.938 versus 0.928). For the same random-forest contextual configuration, excluding the 11 fully anomalous samples yielded similar balanced accuracy (0.935 ± 0.016). Full curve-shape information was more predictive than standard summary properties, while sample-relative contextual descriptors provided a smaller, directionally consistent gain within this NiFe dataset. Because reference labels were assigned while all 64 curves from each sample were viewed together, the context gain may partly reflect expert comparative labelling rather than independent physical evidence. External validation on other material systems or acquisition setups was not performed.

ÖZET

Yüksek verimli nanoindentasyon çok sayıda yük-yer değiştirme eğrisi üretmekte ve manuel anomali taramasını büyük ölçekte güçleştirmektedir. Bu çalışmada, numune-içi göreli bağlamın ölçüm sonrası toplu değerlendirmede uzman etiketli anomalilerin tahminini iyileştirip iyileştirmediği incelenmiştir. Elektrokaplama ile üretilmiş 150 NiFe ince film numunesinden elde edilen 9.600 eğriyi içeren açık veri setinde, güncellenmiş uzman etiketlerine göre 3.409 eğriye (%35,5) anomali etiketi verilmiştir. Tahmin değişkenleri; cihazdan elde edilen özet özellikler, yükleme, bekletme, boşaltma ve kalıcı derinlik davranışlarını tanımlayan öznitelik mühendisliği ile türetilmiş eğri-şekil özellikleri ve anomali etiketleri kullanılmadan aynı numunedeki diğer 63 eğriden hesaplanan numune-içi bağlam tanımlayıcılarından oluşturulmuştur. Lojistik regresyon, rastgele orman ve histogram tabanlı gradyan artırma modelleri, önceden belirlenmiş ayarlarla beş katlı numune-gruplu çapraz doğrulama kullanılarak değerlendirilmiş; aynı numuneye ait 64 indentasyon aynı katta tutulmuştur. Birincil performans ölçütü dengeli doğruluk olarak belirlenmiş ve sonuçlar ortalama ± standart sapma olarak verilmiştir. Bağlamın eklenmesi üç model ailesinde de ortalama dengeli doğruluğu artırmış, en yüksek ortalama rastgele ormanda elde edilmiştir. Rastgele ormanda özet özellikler 0,767 ± 0,011, eğri-şekil özellikleri 0,927 ± 0,017 ve bunların birleşimi 0,928 ± 0,015 dengeli doğruluk sağlamıştır. Bağlam eklendiğinde dengeli doğruluk

0,936 ± 0,013'e, F1 skoru 0,925 ± 0,013'e yükselmiş ve artış beş katın tamamında pozitif olmuştur. Aynı bağlamsız özet ve eğri özellikleriyle rastgele eğri-düzeyi doğrulama, numune-gruplu doğrulamadan biraz daha yüksek bir tahmin vermiştir (0,938'e karşı 0,928). 64 eğrisinin tamamına anomali etiketi verilmiş 11 numune çıkarıldığında performans benzer kalmıştır (0,935 ± 0,016). Bulgular, tam eğri-şekil bilgisinin standart özet özelliklerden daha yüksek tahmin değeri taşıdığını ve numune-içi bağlamın bu NiFe veri setinde daha küçük fakat yön açısından tutarlı bir katkı sağladığını göstermektedir. Ancak referans etiketleri her numunedeki 64 eğri birlikte görülerek oluşturulduğundan, bağlam katkısı bağımsız fiziksel kanıttan ziyade uzmanların karşılaştırmalı etiketleme yaklaşımını kısmen yansıtıyor olabilir. Farklı malzeme sistemleri veya ölçüm düzeneklerinde dış doğrulama yapılmamıştır.

1. INTRODUCTION

The load–displacement response recorded during instrumented nanoindentation provides an established basis for estimating hardness and reduced modulus at small length scales (Oliver & Pharr, 1992, 2004). Bassett et al. (2023) combined high-throughput nanoindentation with other characterization techniques to study combinatorial sets of electrodeposited films. The present analysis uses published data from 150 electrodeposited NiFe samples, each contributing 64 load–displacement curves, for a total of 9,600 curves with expert annotations (Zakariya, Babuska, Mundt, & Henriksen, 2026). The workload associated with expert review motivates machine-assisted anomaly screening for nanoindentation quality control (Zakariya et al., 2026).

Kossman and Bigerelle (2021) trained a convolutional neural network to identify pop-in events in nanoindentation curves. For a different prediction target, Trost et al. (2025) classified and clustered nanoindentation data from high-speed steel and found that feature engineering with curve-derived descriptors improved model performance. These studies support examining curve-derived predictors, while the additional value of within-sample context for distinguishing anomalous from normal curves remains a separate empirical question.

In the NiFe dataset, the expert labelling process included joint viewing of the 64 curves from a physical sample, and the authors explicitly discuss potential per-sample bias (Zakariya et al., 2026). A contextual model is therefore evaluated against judgements formed through a process that itself used sample context. Validation must also reflect the intended prediction target: for hierarchically structured data, performance on new groups is a different question from performance on additional observations within represented groups (Roberts et al., 2017). Here, the relevant group is the physical sample.

This study evaluates whether label-free, sample-relative features improve binary classification of expert-labelled nanoindentation curves beyond individual-curve information when testing on previously unseen physical samples within this NiFe dataset. The comparison adds within-sample context to the same set of individual-curve predictors and keeps all indentations from each physical sample together during validation. Random indentation-level validation serves as a comparator. The intended application is post-acquisition quality control: after all 64 curves from a sample have been acquired, each curve is described relative to the other 63 curves without using their labels. This is a batch setting with transductive context from the unlabelled test-sample curves. The study includes no external validation, so its conclusions concern agreement with the contextual expert labels within this dataset.

2. MATERIALS AND METHODS

2.1. Study design and data provenance

This study used the open nanoindentation dataset described by Zakariya et al. (2026) for secondary machine-learning analysis. The experimental measurements and expert annotations were produced by the original investigators. No new specimens, indentation experiments, or expert annotations were generated for the present study. The dataset contains 150 physical electrodeposited NiFe samples drawn from the characterization study of Bassett et al. (2023), with 64 indentation curves per sample and 400 recorded points per curve. The data are deposited in the Materials Data Facility (Henriksen, Zakariya, Babuska, & Mundt, 2025).

2.2. Dataset assembly and binary target

The revised annotations were read from updated_all_samples_labelled.csv. Records were matched to the modelling table using sample_num and indent_num, yielding 9,600 one-to-one matches with no duplicate keys or unmatched records. All raw-curve paths listed in the annotation file were present in the archive. The binary target was 1 (anomalous) if any of seven revised annotation fields was greater than zero and 0 (normal) otherwise. The fields were fully anomalous sample, force offset, displacement offset, unusual unloading curvature, unusual loading curvature, tip displacement decreases at holding, and too deep. All positive severity levels were included, including level 1, which denotes borderline or less certain annotations in the source taxonomy (Zakariya et al., 2026). This rule yielded 3,409 anomalous and 6,191 normal curves, corresponding to an anomaly prevalence of 35.5%. Recalculation from the annotation fields reproduced every target value in the modelling table.

The categories could overlap and were not treated as mutually exclusive classes. The other text field did not contribute to the binary target; all 31 non-empty, non-zero entries already had a positive taxonomy annotation. The source study used feature-based consistency checks to select curves for expert reinspection, producing the revised annotations. Both initial annotation and reinspection allowed access to within-sample visual context (Zakariya et al., 2026). The prediction target consequently represents contextual expert assessments rather than independently established physical causes.

2.3. Individual-curve features

Four feature sets were compared. Set A comprised ten instrument-reported summaries supplied with the dataset: contact depth, maximum load, stiffness, maximum displacement, effective depth, reduced modulus, hardness, unloading coefficient, final displacement, and unloading exponent. The values were taken from the released per-sample summary files. Their equality to the corresponding modelling-table entries was verified for all 9,600 indentations. These values were retained as predictors of expert labels; their inclusion does not establish that each anomalous curve yields a physically valid mechanical-property estimate. Drift and projected contact area were not included in Set A.

Set B contained 33 descriptors computed from individual depth, load, and time records. Let h_j, P_j, and t_j denote the recorded depth, load, and time at point j. For each curve, the first and last indices satisfying $P_j \geq 0.98$ max(P) were designated a and b. The loading segment comprised points 0 through a, the hold segment a through b, and the unloading segment b through the final point, including the boundary points in both adjacent segments. Feature definitions used these data-derived boundaries rather than assuming a fixed duration for each segment.

Initial load and depth were the medians of the first five recorded points. Maximum load and depth were the respective maxima over the curve, and final load and depth were the last recorded values. Timing descriptors were t_a, t_b, and $t_b - t_a$. Loading work was the signed trapezoidal integral of load with respect to depth over the loading segment; unloading work was the absolute value of the corresponding unloading integral. Their ratio was $W_{unload}/(|W_{load}| + 10^{-9})$, using the recorded units of micronewtons and nanometres. These integrals were used as curve descriptors without asserting a physical energy interpretation for every anomalous trace.

Three monotonicity descriptors measured the fractions of consecutive depth changes that were negative during loading, positive during unloading, or negative during the hold. Hold-depth and hold-load changes were the respective medians of the last ten points minus the medians of the first ten points within the hold segment. Loading-terminal and unloading-initial slopes were obtained by fitting a straight line to load as a function of depth using, respectively, the last 25 loading points and first 25 unloading points. For each loading and unloading segment, depth and load were separately mapped to [0, 1] using that segment's minimum and range. A quadratic was fitted to normalized load as a function of normalized depth, and its root-mean-square residual was retained as a shape descriptor.

At 20%, 40%, 60%, and 80% of the curve's maximum load, the recorded point with the closest load was selected separately within the loading and unloading segments. The two depths and their difference, unloading minus loading, provided twelve further descriptors. These were nearest-recorded-point features, not interpolated depths. Set C combined Sets A and B, giving 43 individual-curve predictors. The instrument-reported maxima in Set A and the maxima recomputed from raw curves in Set B were retained as separate predictors.

2.4. Label-free within-sample context

Set D added 20 contextual descriptors to Set C. Context was constructed from ten quantities: initial load, initial depth, maximum depth, final depth, hardness, reduced modulus, stiffness, hold-depth change, loading quadratic residual, and unloading quadratic residual. For a quantity x belonging to indentation i, the reference comprised the other 63 indentations from the same physical sample. The reference median and median absolute deviation were

m_{-i} = median{x_j : j belongs to the same sample, j ≠ i},

MAD_{-i} = median{$|x_j - m_{-i}|$: j belongs to the same sample, j ≠ i}.

Two descriptors were retained for each quantity:

$z_i = (x_i - m_{-i})/(1.4826\ MAD_{-i} + 10^{-9})$, and $|z_i|$.

The factor 1.4826 scales MAD to the standard-deviation scale under a normal distribution; its use does not assume that the within-sample values are normally distributed. The same numerical value, 10^{-9}, was added to every denominator in the recorded units of the respective quantity, without adapting it to that quantity's typical magnitude. Where the reference MAD was zero, the denominator was therefore 10^{-9}; the resulting descriptors were retained without clipping, with absolute values reaching approximately 2.85×10^9 for initial-depth context. Neither reference construction nor selection of reference curves used anomaly labels or a known-normal subset. The reference statistics therefore describe the sample's mixture of curves and do not necessarily represent normal behaviour. In the 11 samples for which all 64 curves were labelled anomalous, each reference consisted of 63 curves carrying anomalous labels. Their contextual descriptors therefore measure within-sample deviations without a normal-labelled reference. All 64 curves from a sample were assumed available before prediction. Thus, when a sample was held out during validation, its contextual predictors used its own unlabelled curves. This is a post-acquisition batch setting with transductive context. It does not describe prediction from a single isolated indentation. The archived modelling table contained 63 finite, non-constant feature columns. Sample and indentation identifiers were retained for record matching and grouping but were not predictors. Expert notes, other, annotation fields, batch and processing metadata, dates, stage coordinates, point counts, and voltage channels were also excluded as predictors. These exclusions restrict obvious routes for identity- or annotation-based prediction; they do not establish the absence of every possible shortcut.

2.5. Models and computational provenance

Logistic regression (LR), Random Forest (RF), and histogram gradient boosting (HGB) were implemented in scikit-learn (Pedregosa et al., 2011). The documented verification analysis used fixed settings without a hyperparameter search or decision-threshold optimization. Logistic regression used training-fold standardization, L2 regularization, C = 1, the liblinear solver, balanced class weights, random_state = 42, and max_iter = 5000. Standardization parameters were fitted using each training fold and applied to its held-out fold. No imputation was required because the archived feature matrix contained no missing or infinite values. Random Forest and histogram gradient boosting used the unscaled feature matrix.

Random Forest used 120 trees, a minimum of two samples per leaf, balanced_subsample class weights, and random_state = 42. Other structural settings followed scikit-learn 1.8.0 defaults, including Gini impurity, square-root feature subsampling, bootstrap sampling, and no maximum tree depth. Histogram gradient boosting used balanced class weights and random_state = 42 with scikit-learn 1.8.0 defaults: log loss, learning rate 0.1, 100 boosting iterations, at most 31 leaves, at least 20 samples per leaf, no maximum depth, and zero L2 regularization. With early_stopping='auto', fewer than 10,000 observations in each training fold, and no separate validation data supplied to fit, this comparator did not invoke an internal early-stopping validation split. Discrete predictions were obtained using each classifier's predict method; probabilities for class 1 were retained for probability-based metrics.

Historical implementation provenance was incomplete. The original execution script was not available in the retrieved archive. The Random Forest specification was reconstructed by comparison with archived fold-level outputs; it is a numerical fingerprint reconstruction, not recovery of the original code. The logistic-regression verification implementation is likewise explicitly recorded rather than asserted to be the original constructor. The exact historical histogram-gradient-boosting constructor could not be recovered. Its fully specified rerun is therefore reported as a reproducible full-paper comparator, separately from historical results. Reconstruction of historical settings was not presented as an independent model-selection experiment.

2.6. Validation and context ablation

Primary evaluation used five-fold StratifiedGroupKFold with shuffle=True and random_state=42, grouping on the physical sample identifier. Every indentation from a sample was assigned to the same held-out fold. Fold membership was checked for disjoint training and test sample sets. The intended generalization target was previously unseen physical samples within this dataset. Sample grouping prevents indentations from the same physical sample being divided between training and testing; it does not establish independence across fabrication conditions or laboratories.

The same grouped folds and model settings were used across feature sets. The contribution of context was assessed by comparing Set D with Set C for each model and computing paired fold differences. In the documented verification run, a separate Random Forest comparison used Set C under five-fold StratifiedKFold with shuffle=True and random_state=42 at the indentation level. Context features were excluded from this split comparison. Because the random split can place curves from the same physical sample in both training and testing, it addresses a different prediction setting and was treated as a comparator rather than the principal estimate for unseen samples.

2.7. Performance measures and robustness analyses

Balanced accuracy (BA) was specified as the primary performance measure because the binary target was imbalanced, and F1 for the anomalous class was used as the principal secondary measure. If TP, TN, FP and FN denote the true-positive, true-negative, false-positive and false-negative counts, respectively, balanced accuracy was calculated as [TP/(TP+FN) + TN/(TN+FP)]/2 and anomalous-class F1 as 2TP/(2TP+FP+FN). Each curve had unit weight in the confusion-matrix counts; BA then weighted the two class recalls equally. For every model-feature configuration, fold scores were summarized by their unweighted mean and sample standard deviation across the five held-out folds. Precision, recall, area under the receiver operating characteristic curve (ROC-AUC), and average precision were retained as supporting measures. Average precision summarized the precision–recall steps without trapezoidal interpolation.

The incremental contribution of context was evaluated from paired Set D minus Set C differences on the same grouped folds. The direction of each fold difference was recorded as a descriptive check; the five folds were not treated as independent replications, and no formal paired significance test was performed. For the annotation-level description, out-of-fold predictions from the grouped Random Forest Set D model were matched to each positive annotation field. The resulting subtype recall was the proportion of curves carrying a given annotation that received an anomalous binary prediction. Because annotations could overlap, these calculations were not interpreted as a multiclass confusion matrix or as independent class-specific performance estimates.

Three post-hoc robustness analyses were conducted without performance-based hyperparameter tuning or classification decision-threshold optimization. First, the 20 contextual columns in Set D were symmetrically clipped at -100 and +100, and then at -10 and +10. Set C, the 43 non-contextual columns in Set D, the leave-one-indentation-out reference statistics, the 10^{-9} denominator constant, the grouped folds, the remaining model settings and the prediction threshold were left unchanged. Second, the Random Forest C–D comparison was repeated with max_features fixed at 6 for both sets and at 7 for both sets. Runtime inspection of the fitted trees confirmed the nominal max_features setting under each condition. Third, the 11 samples whose 64 binary targets were all positive were removed. This target-defined exclusion retained 139 samples and 8,896 curves. A new five-fold StratifiedGroupKFold split was generated once on the retained samples and applied identically to paired Random Forest Set C and Set D fits. This analysis was retrospective and was not proposed as a label-free deployment filter.

2.8. Reproducibility and scope

The evidence package records the hashes of the analysis inputs, feature definitions, software environment, model constructors, fold assignments, fold-level metrics and row-level out-of-fold probabilities and predictions. The documented run used Python 3.12.14, scikit-learn 1.8.0, NumPy 2.3.5 and pandas 2.2.3. The ten instrument-summary variables were checked against the released summary files. The remaining descriptors were reconstructed from the released curves or within-sample values and compared with the archived modelling table using $|\text{archived} - \text{reference}| \leq 10^{-8} + 10^{-8}|\text{reference}|$. Here, reference denotes either the released summary value or the independently recomputed value. This comparison establishes numerical agreement for the released data, but it does not establish that the

unavailable historical feature-extraction code was identical or that it would behave identically in unobserved boundary cases. The source curves, instrument summaries and revised annotations are archived in the Materials Data Facility (Henriksen et al., 2025). The analysis-derived feature table, fold assignments and row-level predictions have been retained in the project evidence package, but have not been deposited in a public repository.

Before the post-hoc controls were interpreted, the six baseline C–D model configurations were refitted on the archived grouped folds and compared with the saved verification-run outputs (model_verification.json and model_oof.json). Their held-out sample lists matched the archive, their hard predictions had zero mismatches, the largest absolute probability difference was 2.22×10^{-16}, and the largest fold-metric difference was zero. The saved robustness outputs were subsequently re-aggregated from the row-level predictions by a separate verification script. These checks demonstrate internal computational reproducibility of the documented pipeline; they are not an external replication of the scientific findings.

The robustness analyses answer deliberately narrow questions. Clipping at the two specified thresholds does not identify a uniquely correct denominator guard or a unit-aware alternative to the 10^{-9} constant. Holding Random Forest max_features at 6 or 7 controls the candidate-feature count but not every change in representation or feature-sampling probability produced by adding 20 predictors. The exclusion analysis is defined by expert targets and contains no test of entirely normal samples. More broadly, the study remains confined to the released NiFe dataset and its contextual expert annotations. No external material system, laboratory, instrument configuration or independently labelled cohort was evaluated.

3. RESULTS AND DISCUSSION

3.1. Feature representation and classification performance

Among the evaluated configurations, the largest differences in mean balanced accuracy arose across feature sets rather than across classifiers within a set. Across 9,600 curves from 150 physical samples, Set A, which contained ten instrument-reported summaries, produced mean balanced accuracy values between 0.7499 and 0.7718. With the 33 curve-derived descriptors in Set B, the range rose to 0.9262–0.9281 (Table 1). These results indicate that the derived descriptors carried information associated with the expert anomaly labels that the instrument summaries did not capture as effectively. They do not identify a physical failure mechanism, and Sets A and B differ in both feature type and feature count. The finding is qualitatively consistent with the value of curve-derived features reported for a different nanoindentation classification problem by Trost et al. (2025), but the different materials, targets and validation designs preclude a direct comparison of scores.

Table 1. ***Classification performance under five-fold sample-grouped validation***

Model	Feature set	Predictors	Balanced accuracy	Anomalous-class F1
LR	A	10	0.7499 ± 0.0190	0.6761 ± 0.0280
LR	B	33	0.9281 ± 0.0105	0.9107 ± 0.0087
LR	C	43	0.9276 ± 0.0098	0.9095 ± 0.0075
LR	D	63	0.9328 ± 0.0098	0.9165 ± 0.0082
RF	A	10	0.7674 ± 0.0109	0.6987 ± 0.0170
RF	B	33	0.9268 ± 0.0168	0.9133 ± 0.0191
RF	C	43	0.9278 ± 0.0145	0.9140 ± 0.0164
RF	D	63	0.9356 ± 0.0127	0.9245 ± 0.0125
HGB	A	10	0.7718 ± 0.0103	0.7054 ± 0.0139
HGB	B	33	0.9262 ± 0.0194	0.9099 ± 0.0213
HGB	C	43	0.9245 ± 0.0229	0.9070 ± 0.0271
HGB	D	63	0.9326 ± 0.0175	0.9193 ± 0.0189

Note. Values are unweighted means ± sample standard deviations across five held-out folds. LR = logistic regression; RF = Random Forest; HGB = histogram gradient boosting. A contains instrument-reported summaries; B contains descriptors derived from individual load, depth and time records; C combines A and B; D adds 20 within-sample contextual descriptors to C.

Adding Set A to Set B did not produce a consistent improvement. Relative to B, Set C gave a small increase for Random Forest but small decreases for logistic regression and histogram gradient boosting. More predictors were therefore not automatically beneficial under the documented settings. The controlled context comparison is C versus D.

Adding the 20 contextual descriptors to Set C increased mean balanced accuracy and anomalous-class F1 for all three classifiers (Table 2). The balanced-accuracy increments were 0.005177 for logistic regression, 0.007770 for Random Forest and 0.008047 for histogram gradient boosting. For Random Forest, these mean gains corresponded to 0.777 percentage points in balanced accuracy and 1.051 percentage points in anomalous-class F1. Balanced accuracy increased in five of five folds for Random Forest and histogram gradient boosting and in four of five folds for logistic regression. F1 increased in all five folds for every model. The absolute changes were modest, and the fold signs are descriptive rather than evidence from five independent replications. The reported standard deviations are not confidence intervals, and overlap among the training sets limits formal inference from the folds (Bengio & Grandvalet, 2004).

Table 2 ***Paired changes after adding within-sample context***

Model	Mean change in BA	BA-positive folds	Mean change in F1	F1-positive folds
LR	+0.005177	4/5	+0.006971	5/5
RF	+0.007770	5/5	+0.010511	5/5
HGB	+0.008047	5/5	+0.012308	5/5

Note. Changes are Set D minus Set C and were calculated from unrounded scores on the same grouped folds. No formal significance test was performed.

Among the 12 primary model-feature configurations, RF-D had the highest mean balanced accuracy (0.9356) and F1 (0.9245). The ranking was not uniform across metrics: LR-D had higher anomalous-class recall than RF-D (0.9013 versus 0.8903), whereas RF-D had higher precision (0.9623 versus 0.9328). Selection for a practical workflow would therefore depend on the relative cost of a missed anomaly and an additional expert review, neither of which was measured here.

3.2. Validation design and target-defined sample exclusion

For RF-C, random indentation-level folds yielded balanced accuracy of 0.9375 ± 0.0073 and anomalous-class F1 of 0.9278 ± 0.0084; grouped folds yielded 0.9278 ± 0.0145 and 0.9140 ± 0.0164, respectively. The balanced-accuracy means differed by 0.009677 (approximately 0.968 percentage points). Every random fold included curves from all 150 samples in both training and testing, whereas grouped folds held out complete samples. The former evaluates additional curves from represented samples; the latter evaluates unseen physical samples within this dataset (Roberts et al., 2017). Because grouping also changes split composition, the score gap is not a causal estimate of a particular leakage mechanism.

Table 3 ***Random and grouped validation and the target-defined exclusion subset***

Table 3, panel A

Analysis	Model and set	Samples	Curves
Random indentation-level split	RF-C	150	9,600
Sample-grouped split	RF-C	150	9,600
Exclusion subset	RF-C	139	8,896

Analysis	Model and set	Samples	Curves
Exclusion subset	RF-D	139	8,896

Table 3, panel B

Analysis	Model and set	Balanced accuracy	Anomalous-class F1
Random indentation-level split	RF-C	0.9375 ± 0.0073	0.9278 ± 0.0084
Sample-grouped split	RF-C	0.9278 ± 0.0145	0.9140 ± 0.0164
Exclusion subset	RF-C	0.929893 ± 0.015751	0.914564 ± 0.014534
Exclusion subset	RF-D	0.935234 ± 0.015760	0.923601 ± 0.016331

Note. The random and grouped full-data rows use different split structures. The exclusion rows use the same newly generated grouped folds for C and D. Values are not equivalence estimates across populations.

Removing the 11 samples with 64 positive targets retained 139 samples, 8,896 curves, 2,705 anomalous curves and 6,191 normal curves. On the same regenerated grouped folds, RF-D exceeded RF-C by 0.005341 in mean balanced accuracy and 0.009037 in mean F1; both differences were positive in all five folds. The balanced-accuracy increment was smaller than the full-data RF increment of 0.007770. Thus, the direction persisted but its magnitude changed. Because expert targets defined the exclusion, this is a retrospective sensitivity analysis, not a pre-labelling deployment rule. Similar mean scores in the full and reduced data do not constitute an equivalence test.

3.3. Post-hoc robustness controls

Zero leave-one-indentation-out MAD values produced extreme contextual descriptors, with a largest absolute value of 2.850804×10^{9}. Clipping at ±100 changed 292 cells in 142 curves across 24 samples; clipping at ±10 changed 5,112 cells in 2,334 curves across all 150 samples. Mean Set D minus Set C balanced accuracy and F1 stayed positive for all three classifiers under both thresholds (Table 4), but the increments varied. Logistic regression's balanced-accuracy increment fell from 0.005177 without clipping to 0.002932 at ±10; Random Forest's was 0.010497 at ±100 and 0.006825 at ±10. HGB at ±10 had a positive mean increment, although balanced accuracy increased in four rather than five folds. The checks support the direction of the mean result at these thresholds, not an invariant magnitude or fold pattern.

Table 4*Context gain under the two clipping thresholds*

Table 4, panel A

Model	D condition	Balanced accuracy	Anomalous-class F1
LR	Unclipped	0.932764	0.916463
LR	Clip 100	0.932214	0.915621
LR	Clip 10	0.930520	0.913455
RF	Unclipped	0.935571	0.924534
RF	Clip 100	0.938298	0.927540
RF	Clip 10	0.934626	0.923413
HGB	Unclipped	0.932572	0.919305
HGB	Clip 100	0.932572	0.919305

Model	D condition	Balanced accuracy	Anomalous-class F1
HGB	Clip 10	0.933163	0.920721

Table 4, panel B

Model	D condition	Change in BA vs C	Change in F1 vs C	BA/F1-positive folds
LR	Unclipped	+0.005177	+0.006971	4/5 / 5/5
LR	Clip 100	+0.004627	+0.006129	4/5 / 5/5
LR	Clip 10	+0.002932	+0.003963	4/5 / 4/5
RF	Unclipped	+0.007770	+0.010511	5/5 / 5/5
RF	Clip 100	+0.010497	+0.013517	5/5 / 5/5
RF	Clip 10	+0.006825	+0.009390	5/5 / 5/5
HGB	Unclipped	+0.008047	+0.012308	5/5 / 5/5
HGB	Clip 100	+0.008047	+0.012308	5/5 / 5/5
HGB	Clip 10	+0.008638	+0.013725	4/5 / 5/5

Note. Only the 20 contextual columns were clipped. The feature base in C, reference construction, denominator constant, folds, remaining model settings and classification decision threshold were unchanged.

The square-root max_features rule gave nominal candidate counts of six for Set C and seven for Set D. The C–D comparison was therefore repeated with the candidate count fixed at six and at seven for both sets (Table 5). The fold-level balanced-accuracy differences were positive in all five folds under both controls, with mean increments of 0.007538 for six candidates and 0.008919 for seven. The corresponding F1 increments were 0.010234 and 0.011568. The persistent positive differences indicate that the nominal one-feature difference in candidate count does not by itself explain the gain. They do not isolate context from every consequence of adding 20 predictors, because the representation and the probabilities with which individual predictors are sampled still change.

Table 5 ***Random Forest C–D comparison with a fixed candidate-feature count***

Table 5, panel A

Condition	Nominal C / D candidate count	C balanced accuracy	D balanced accuracy
Square-root rule	6 / 7	0.927801	0.935571
Fixed 6	6 / 6	0.927801	0.935340
Fixed 7	7 / 7	0.926652	0.935571

Table 5, panel B

Condition	Nominal C / D candidate count	Change in BA	Change in F1	BA/F1-positive folds
Square-root rule	6 / 7	+0.007770	+0.010511	5/5 / 5/5
Fixed 6	6 / 6	+0.007538	+0.010234	5/5 / 5/5
Fixed 7	7 / 7	+0.008919	+0.011568	5/5 / 5/5

3.4. Detection across annotation categories

The grouped RF-D predictions did not perform uniformly across the seven annotation subsets (Table 6). RF-D predicted the anomalous class for 1,333 of 1,348 curves carrying a force-offset annotation and 952 of 989 carrying an unusual-unloading-curvature annotation. At the other end of the range, only 85 of 139 displacement-offset curves and 74 of 227 unusual-loading-curvature curves received an anomalous prediction. The latter corresponds to recall of 0.3260, despite the much stronger aggregate F1. Aggregate performance therefore should not be read as uniformly high detection across the annotation taxonomy.

Table 6 ***RF-D detection among curves carrying each anomaly annotation***

Annotation	Labelled curves	Represented samples	Detected curves	Recall
Force offset	1,348	132	1,333	0.9889
Unusual unloading curvature	989	140	952	0.9626
Fully anomalous sample	704	11	632	0.8977
Tip displacement decreases at holding	223	111	186	0.8341
Too deep	84	36	69	0.8214
Displacement offset	139	52	85	0.6115
Unusual loading curvature	227	69	74	0.3260

Note. Detected curves were assigned the anomalous binary class by their held-out RF-D model. Recall was calculated from pooled out-of-fold predictions within each annotated subset. Annotations can overlap, so the rows are not mutually exclusive or independent classes.

These values quantify binary detection among curves that carry an annotation; they do not show that the model recognized the annotation itself. A curve with several annotations may have received an anomalous prediction because of another irregularity. The 704 curves in the fully anomalous category are clustered within 11 physical samples, which limits any interpretation that treats them as 704 independent examples. The present analysis does not determine why unusual loading curvature was frequently missed. Resolving that question would require targeted inspection of the missed curves and, ideally, annotation evidence independent of the current feature and sample context.

3.5. Interpretation and scope

The contextual descriptors place each indentation relative to the other 63 measurements from its physical sample. This is relevant to the prediction target because the source expert viewed all 64 curves together, and feature-derived consistency checks then selected curves for expert re-review (Zakariya et al., 2026). The revised target may therefore reflect curve patterns emphasized during that review. The size of any such contribution to the model comparison cannot be isolated here; this limit of target construction differs from physical-sample overlap between training and test folds. The contribution tested here is narrower than the introduction of sample context itself: it is the addition of a specified, label-free within-sample reference representation to a fixed individual-curve feature base, evaluated with complete physical samples held out. The resulting gain measures closer agreement with contextual expert labels. It does not independently verify the physical origin of the labelled irregularities.

The robustness controls reduce three specific concerns without removing all uncertainty. Mean C–D differences remained positive for all three classifiers under both clipping thresholds; the Random Forest difference also remained positive when candidate-feature counts were equalized and when the 11 fully anomalous samples were removed. At the same time, the clipping results changed the magnitude of the gain, the fixed-count comparison did not hold the full representation constant, and the exclusion subset was defined using the target. These findings strengthen the internal case that the result is not explained solely by the tested extreme values, the nominal 6-versus-7 Random Forest candidate count or the fully anomalous samples. They do not convert the comparison into a causal estimate of a pure context mechanism.

The deployment setting is also constrained. Context for a new curve cannot be computed until the other curves from the same sample are available, so the approach is suitable for post-acquisition batch review rather than isolated real-time prediction. The reference distribution is a mixture of measurements and is not a known-normal control. Under the binary target used here, every sample contains at least eight positive curves, and 11 samples contain 64; consequently, performance on entirely normal samples or samples with very low within-sample anomaly prevalence remains unknown. Grouping prevents curves from the same physical sample from appearing in both training and test sets, but it does not establish independence across fabrication conditions, instruments or laboratories.

Finally, all model development and evaluation reported here use one released NiFe dataset. Fixed settings in the documented run do not prove that all earlier representation choices were made independently of observed performance, and such choices can influence estimated generalization (Cawley & Talbot, 2010). Transfer to another material system or acquisition workflow requires external data and independently generated labels. Practical deployment would also require decision thresholds selected for deployment, an explicit account of the costs of false negatives and additional reviews, and direct measurement of whether the system reduces expert workload. The present evidence supports further evaluation of within-sample context for batch screening; it does not support replacement of expert review.

4. CONCLUSION AND RECOMMENDATIONS

In this secondary analysis, the curve-derived descriptors in Set B predicted the revised expert anomaly labels more accurately than the instrument-reported summaries in Set A under sample-grouped validation. Adding 20 within-sample descriptors to the same 43 individual-curve predictors produced smaller positive mean gains in all three model families. Random Forest with Set D achieved balanced accuracy of 0.9356 ± 0.0127 and anomalous-class F1 of 0.9245 ± 0.0125. Relative to Set C, the corresponding increases were 0.007770 and 0.010511, with positive differences in all five grouped folds for both measures. These fold results are descriptive; no formal significance test was performed.

Clipping the contextual descriptors at either tested threshold left mean Set D minus Set C differences in balanced accuracy and F1 positive for all three classifiers, although their magnitudes changed. In Random Forest, the mean gains also remained positive when the nominal max_features setting was equal for Sets C and D, and when the 11 samples with 64 positive targets were excluded before both configurations were refitted. At the ±10 clipping threshold, histogram gradient boosting had a positive mean balanced-accuracy difference but a positive difference in only four of five folds. These checks address specific sensitivities; they do not separate the information in context from every other consequence of expanding the feature set.

The target is an expert judgement formed with access to all 64 curves from a sample, so closer agreement with that target does not independently establish the physical origin of a labelled irregularity. The contextual features require the other curves before prediction and therefore suit post-acquisition batch review. Evaluation on other materials, instruments, laboratories, entirely normal samples, and samples with low within-sample anomaly prevalence remains open. Further work should test independently generated expert labels in such settings, inspect the missed unusual-loading-curvature cases, and measure whether alternative decision thresholds reduce expert-review workload without an unacceptable increase in missed anomalies. The approach remains a candidate aid to expert screening, not a validated replacement for it.

ÖZET

Günümüzde depolama mobilyalarının farklı kullanım alanları ve kullanıcı gereksinimlerine cevap verebilmesi, ürünlerin yalnızca belirli ölçü ve fonksiyonlara göre geliştirilmesi yerine farklı kullanım senaryolarına uyarlanabilen tasarım yaklaşımlarını gerekli hale getirmektedir. Farklı ölçü ve fonksiyonlar için ayrı ürünlerin tasarlanması; parça çeşitliliğinin artması, üretim süreçlerinin karmaşıklaşması, stok yönetiminin zorlaşması ve montaj süreçlerinin uzaması gibi sorunları beraberinde getirebilmektedir. Bu çalışmada, farklı kullanım ihtiyaçlarına uyarlanabilen, modüler yapıya sahip, yapısal dayanımı ve malzeme kullanımı dikkate alınarak kurgulanmış ve seri üretime uygun bir depolama dolap sisteminin tasarım ve geliştirme yaklaşımı ele alınmıştır.

Geliştirilen sistem, temel taşıyıcı elemanların ortak kullanımı prensibine dayandırılmış; farklı genişlik ve kapasitedeki ürünlerin mümkün olduğunca aynı temel komponentlerin farklı kombinasyonlarıyla oluşturulması amaçlanmıştır. Tasarım sürecinde modüler yapı, ortak komponent kullanımı, parça sayısının azaltılması, yapısal rijitlik, yük aktarımının dengelenmesi, montaj kolaylığı, üretim süreçlerinin sadeleştirilmesi, malzeme kullanımının optimize edilmesi ve farklı ölçülere uyarlanabilirlik temel kriterler olarak değerlendirilmiştir. Dikey ve yatay taşıyıcı elemanların belirli bir geometrik düzen içerisinde bir araya getirilmesiyle tekil modülden çoklu ve genişletilebilir sistemlere uzanan ölçeklenebilir bir ürün mimarisi oluşturulması hedeflenmiştir.

Yapısal tasarımda taşıyıcı elemanların konumları, bağlantı noktaları ve yük aktarım yolları dikkate alınarak yükün sistem içerisinde dengeli dağıtılması ve yeterli yapısal dayanımın gereğinden fazla malzeme kullanımına gidilmeden sağlanması esas alınmıştır. Üretilebilirlik açısından ortak parça kullanımının artırılması, parça çeşitliliğinin azaltılması, tekrarlanabilir üretim geometrilerinin ve standart bağlantı elemanlarının kullanılması ile üretim ve montaj işlemlerinin sadeleştirilmesi hedeflenmiştir. Sonuç olarak çalışma; modülerlik, yapısal dayanım, üretilebilirlik ve kullanım esnekliğini ortak bir ürün mimarisi içerisinde bütünleştiren, farklı kullanım alanlarına uyarlanabilir ve seri üretime yönelik bir depolama dolap sistemi tasarım yaklaşımı ortaya koymaktadır.

Anahtar kelimeler: Modüler tasarım, depolama dolabı, yapısal optimizasyon, üretilebilirlik, ürün geliştirme, seri üretim, tasarım mühendisliği.

ABSTRACT

Today, the need for storage furniture to meet the requirements of different application areas and users has made it necessary to adopt design approaches that can be adapted to various usage scenarios rather than developing products solely according to specific dimensions and functions. Designing separate products for different dimensions and functions may lead to increased part variety, greater complexity in production processes, difficulties in inventory management, and longer assembly processes. This

study presents the design and development approach of a modular storage cabinet system that can be adapted to different usage requirements, considers structural strength and material utilization, and is suitable for mass production.

The developed system is based on the principle of using common load-bearing elements, with the aim of creating products of different widths and capacities through various combinations of the same basic components wherever possible. During the design process, modularity, common component utilization, reduction in the number of parts, structural rigidity, balanced load transfer, ease of assembly, simplification of production processes, optimization of material use, and adaptability to different dimensions were considered as the main design criteria. By arranging vertical and horizontal load-bearing elements within a defined geometric configuration, a scalable product architecture extending from a single module to multiple and expandable systems was established.

In the structural design, the positions of the load-bearing elements, connection points, and load transfer paths were considered to achieve a balanced distribution of loads throughout the system and to provide adequate structural strength without excessive material use. In terms of manufacturability, the design focused on increasing the use of common parts, reducing part variety, employing repeatable production geometries and standard connection elements, and simplifying production and assembly operations. As a result, this study presents a storage cabinet design approach that integrates modularity, structural strength, manufacturability, and flexibility within a common product architecture, offering adaptability to different application areas and suitability for mass production.

Keywords: Modular design, storage cabinet, structural optimization, manufacturability, product development, mass production, design engineering.

INTRODUCTION

Today, the diversification of user requirements, the need to adapt to different application areas, and expectations for efficiency in manufacturing processes have made it necessary to adopt more flexible design approaches rather than developing products based solely on a single usage scenario or fixed dimensions. Particularly for product groups with varying dimensional, capacity, and functional requirements, increasing product variety provides advantages in meeting user needs; however, it may also introduce additional complexity into manufacturing systems in terms of part variety, inventory management, assembly operations, and production planning. Studies investigating the effects of product variety on manufacturing performance have shown that complexity arising particularly from part and option variety can negatively affect production performance (MacDuffie et al., 1996; Fisher and Ittner, 1999). Therefore, achieving an appropriate balance between the flexibility provided by product variety and the complexity arising in manufacturing processes has become an important issue in product development.

In this context, modular design has emerged as an important product development approach that enables different user requirements to be addressed through a common product platform. Product architecture is generally defined as the structure that determines how the functions of a product are allocated to physical components and how these components interact with one another (Ulrich, 1995). In modular product architecture, specific functions or structural sections of a product are organized into defined modules, allowing different product configurations to be developed within the same basic system. Modularity has been reported to be directly associated with product change, product variety, component standardization, and product development management (Ulrich, 1995). Similarly, the use of standardized component interfaces can facilitate the flexible development of different products or product variants (Sanchez and Mahoney, 1996).

One of the main objectives of the modular product development approach is to create a greater number of product variants using a limited number of basic components wherever possible. Studies on modularity focus on developing product architectures based on common modules and defined standards rather than completely redesigning products independently from one another (Gershenson et al., 2004). Dahmus et al. (2001) stated that the use of common and interchangeable modules within a product family can enable different products to be developed within a shared architecture. Similarly, product family and product platform approaches are based on creating product variants that address different user requirements through the use of common components and subsystems within the same basic design infrastructure (Jiao et al., 2007). This approach is particularly important for the systematic development of product families in product groups with varying dimensional and capacity requirements.

The use of common components is one of the important manufacturing-related aspects of modular product architecture. Collier (1981) investigated the relationship between component commonality and manufacturing system performance and demonstrated that part standardization can influence manufacturing variables such as total cost, work-center load, and delivery performance. Fisher et al. (1999) stated that component sharing, which involves using the same component across different products, represents an approach for controlling part variety in manufacturing operations while maintaining product variety in the market. The use of common components may also contribute to manufacturing different products within the same production infrastructure, thereby facilitating the management of the relationship between product variety and manufacturing complexity (Kim and Chhajed, 2000; Desai et al., 2001). Nevertheless, component commonality should be evaluated by considering the requirements of the product family and the need for differentiation among individual products.

Increasing product variety can affect not only the design process but also manufacturing and assembly operations. Fisher and Ittner (1999) demonstrated that variability in product options can influence manufacturing labor, production-line downtime, rework, and inventory levels. Salvador et al. (2002) indicated that modular product architecture can serve as an important means of reducing the adverse effects of product variety on operational performance; however, they emphasized that the appropriate modularity approach should be evaluated together with manufacturing characteristics such as production volume and product variety. Therefore, modular design can be regarded not merely as a method for creating different product options, but as an integrated design approach for managing the complexity generated by product variety within manufacturing systems.

Considering product design together with manufacturing and assembly requirements is also important for improving manufacturability. The design-for-manufacture-and-assembly approach is based on fundamental principles such as reducing the number of parts, facilitating the manufacture and assembly of components, and simplifying manufacturing processes as much as possible during product development (Dewhurst and Boothroyd, 1987; Boothroyd et al., 2011). Systematic engineering design approaches also recommend considering criteria such as manufacturing, assembly, cost, and product family development during the early stages of the design process, in addition to the functional requirements of the product (Pahl et al., 2007). Design decisions should therefore not be considered independently of manufacturing; instead, product geometry, number of parts, connection methods, and manufacturing methods should be evaluated in an integrated manner (Ulrich and Eppinger, 2016).

In modular systems, satisfying structural requirements is as important as manufacturability. Transforming a product into a modular system directly affects the design of connections between modules, load-bearing elements, and load-transfer paths. Therefore, modularity should not be regarded simply as dividing a product into separate parts; rather, a product architecture should be established in which functions, geometry, component relationships, and interfaces are systematically defined (Ulrich, 1995; Gershenson et al., 2004). In the development of modular products, the combined consideration of functional structures and common components supports the creation of different product variants based on the same fundamental system (Dahmus et al., 2001). Furthermore, increasing the use of common components and organizing a product family around a defined platform can contribute to establishing a reusable infrastructure for product development and manufacturing processes (Simpson et al., 2006; Jiao et al., 2007).

From the perspective of storage furniture, different application areas involve varying requirements in terms of width, height, capacity, and layout. The variation in storage requirements across offices, healthcare facilities, educational environments, archive areas, commercial spaces, and industrial workplaces highlights the importance of developing systems that can be adapted to different conditions rather than relying solely on individual products with fixed dimensions. Developing an entirely different construction for each dimension and capacity may increase part variety, diversify manufacturing operations, and complicate inventory management. Considering the effects of product variety on operational performance reported in the literature (Fisher and Ittner, 1999; Salvador et al., 2002), as well as the potential contributions of common component utilization to manufacturing systems (Collier, 1981; Fisher et al., 1999), the application of modular product architecture to storage systems represents an appropriate design approach for addressing these requirements in an integrated manner.

Accordingly, the aim of this study is to design and develop a storage cabinet system that can be adapted to different usage requirements, has a modular structure, is based on the use of common components,

considers structural strength and material utilization together, and is suitable for mass production. In the developed system, products with different widths and capacities were intended to be created, as far as possible, through different combinations of the same basic load-bearing components. Throughout the design process, modular structure, common component utilization, reduction in the number of parts, structural rigidity, balanced load transfer, ease of assembly, simplification of manufacturing processes, optimization of material use, and adaptability to different dimensions were considered as the main design criteria. Thus, the study aimed to establish a product architecture extending from a single module to multiple and expandable systems, adaptable to different usage scenarios, and compatible with a mass-production approach.

METHOD

In this study, a systematic design approach was applied to develop a modular storage cabinet system that can be adapted to different usage requirements and is suitable for mass production. The design and development process was addressed in five main stages: conceptual design, identification of common components, structural evaluation, optimization of manufacturing and assembly processes, and visualization and validation.

Determination of Design Requirements and Conceptual Design

In the first stage of the study, the fundamental design criteria required to adapt the storage system to different application areas and user needs were identified. In this context, modularity, common component utilization, reduction in the number of parts, structural rigidity, balanced load transfer, ease of assembly, simplification of manufacturing processes, optimization of material use, and adaptability to different dimensions were considered as the main design criteria.

Based on these criteria, the conceptual design was developed around a single module representing the basic structural unit of the system. The design approach was based on combining individual modules in different configurations, thereby enabling storage systems of different widths and capacities to be created within the same fundamental product architecture.

Development of the Modular Product Architecture

In the modular system design, the basic load-bearing structure was formed by arranging vertical and horizontal elements within a defined geometric configuration. While the vertical elements constituted the main load-bearing structure of the system, the horizontal elements were utilized to form storage compartments and contribute to the structural rigidity of the system.

The product architecture was developed according to the following approach:

Single Module → Module Group → Expandable System

Thus, products with different dimensions and capacities were intended to be created by using a single basic module in different numbers and combinations. Rather than developing entirely new constructions for different product dimensions, this approach was based on using different combinations of the same basic components.

Identification of Common Components

In the next stage of the design process, the basic load-bearing elements that could be commonly used across different product configurations were identified. The common component approach aimed to enable the same parts to be used in different module combinations and to achieve product variety through a limited number of basic components wherever possible.

Accordingly, the basic load-bearing elements were retained while adapting the system to different widths and capacities, whereas product variants were created through different geometric combinations of these elements. In this way, the design aimed to reduce part variety, increase common component utilization, and enable different products to be developed within the same fundamental design infrastructure.

Evaluation of Structural Design and Load Transfer

In the structural design of the system, the positions of the load-bearing elements, connection points, and load transfer paths were taken into consideration. To enable the storage system to carry loads that may occur during use, the arrangement of vertical load-bearing elements within the system, the contribution

of horizontal elements to structural rigidity, the geometry of the connection points, and the transfer of loads in the vertical direction were evaluated as part of the design process.
By positioning the load-bearing elements within a defined geometric arrangement, a balanced distribution of loads throughout the system was targeted. At the same time, the design aimed to provide adequate structural strength while avoiding excessive material use, thereby maintaining a balance between structural strength and material utilization.

Evaluation in Terms of Manufacturability and Assembly

The suitability of the developed modular system for mass production was considered one of the main criteria of the design process. In this context, increasing the use of common parts, reducing part variety, utilizing repeatable manufacturing geometries, employing standard connection elements, and simplifying assembly operations were targeted.
Through a product architecture based on the use of the same basic components in different product configurations, products of different dimensions were intended to be manufactured using a common production approach. In this way, the design aimed to prevent unnecessary diversification of manufacturing processes while increasing product variety and to enable production and assembly operations to be carried out in a more standardized manner.

Visualization and Design Validation

In the final stage of the design process, the developed modular product architecture was evaluated through three-dimensional visualizations. Product variants that could be created by combining the basic modules in different configurations were examined, and the adaptability of the system to different usage scenarios was visually evaluated.
At this stage, the applicability of the same module family to different product configurations was considered, while maintaining the fundamental product architecture during the transition from a single module to larger systems. Thus, the developed system was evaluated as a whole in terms of modularity, common component utilization, structural design, manufacturability, ease of assembly, and adaptability to different application areas.

RESEARCH FINDINGS AND DISCUSSION

The storage system developed in this study was evaluated in terms of modular product architecture, common component utilization, structural configuration, manufacturability, and adaptability to different usage requirements. As a result of the design process, a scalable product architecture ranging from a single module to multiple and expandable systems was established by using different combinations of basic load-bearing elements. Thus, products with different dimensions and capacities were intended to be created through various combinations of the same basic components without the need to develop entirely new constructions. This approach is consistent with studies indicating that modular product architecture enables different product variants to be developed within a common design infrastructure (Ulrich, 1995; Gershenson et al., 2004; Jiao et al., 2007).
In the developed system, vertical and horizontal load-bearing elements were arranged within a defined geometric configuration. The positions of the load-bearing elements, connection points, and load transfer paths were considered to achieve a balanced transfer of loads throughout the system. In addition, increasing common component utilization, reducing part variety, employing repeatable manufacturing geometries and standard connection elements, and simplifying production and assembly operations were targeted. The potential contributions of common component utilization to managing product variety and standardizing manufacturing processes have also been emphasized in the literature (Collier, 1981; Fisher et al., 1999; Salvador et al., 2002).
Evaluations based on three-dimensional visualizations showed that the same module family could be adapted to different product configurations. The modular bookcase/TV unit combination and executive desk application were considered examples of the implementation of this approach in different usage scenarios. Overall, the developed design approach integrates modularity, structural strength, manufacturability, and flexibility of use within a common product architecture. However, the structural performance of the system should be further validated through numerical analyses and experimental tests. Future studies may also include comparisons with existing systems in terms of production time, material consumption, number of parts, and cost.

CONCLUSION

In this study, a modular storage cabinet system adaptable to different usage requirements and suitable for mass production was developed. A scalable product architecture capable of accommodating various dimensions and capacities was established by using different combinations of common load-bearing elements. Throughout the design process, structural strength, balanced load transfer, manufacturability, ease of assembly, and material utilization were considered together. The proposed approach is considered to contribute to managing product variety through common components and enabling products for different application areas to be developed within the same design infrastructure. Future studies are planned to validate the structural performance of the system through numerical analyses and experimental methods.

ÖZET
Üretim süreçlerinde kalite, süreklilik ve verimliliğin sağlanması, özellikle kaynaklı imalat uygulamalarında ürün standardizasyonu açısından büyük önem taşımaktadır. Robotik kaynak sistemleri; kaynak hızı, kaynak noktaları ve proses parametrelerinin önceden tanımlanabilmesi ve üretim çevrimleri boyunca tekrarlanabilmesi sayesinde kaynak prosesinin daha kontrollü yürütülmesine olanak sağlamaktadır. Bununla birlikte, robot sisteminin yüksek konumlandırma ve tekrarlama hassasiyeti, ürün geometrisinin ve ölçüsel özelliklerin her üretim çevriminde aynı şekilde korunması için tek başına yeterli değildir. Kaynak yapılacak parçaların doğru referans noktalarına göre konumlandırılması ve kaynak işlemi süresince sabit tutulması gerekmektedir. Bu çalışmada, robotik kaynak sistemlerinin üretimde sağladığı avantaj ve sınırlamalar ile kaynak fikstürlerinin ürün standardizasyonu, ölçüsel tekrarlanabilirlik ve proses verimliliği üzerindeki etkileri değerlendirilmiştir. Ayrıca Nitrocare Ar-Ge Merkezi bünyesinde tasarlanan ve üretilen kaynak fikstürlerinin geliştirme ve uygulama süreçleri incelenmiştir. Yapılan değerlendirmeler sonucunda, kaynak fikstürlerinin parçaların doğru referanslanması, konumlandırılması ve sabitlenmesi yoluyla ürün geometrisinin korunmasına ve üretim çevrimleri arasındaki ölçüsel tekrarlanabilirliğin sağlanmasına katkı sunduğu görülmüştür. Bununla birlikte fikstür tasarımında ürün geometrisi, kaynak sırası, robot hareketleri, operatör ergonomisi, üretim adedi ve kalite gereksinimlerinin birlikte değerlendirilmesi gerektiği belirlenmiştir. Sonuç olarak, robotik kaynak proseslerinde ürün standardizasyonunun yalnızca robot sisteminin hassasiyetine bağlı olmadığı; robot, ürün, kaynak parametreleri ve kaynak fikstürünün bütüncül olarak ele alınması gerektiği değerlendirilmiştir. Doğru tasarlanan ve doğrulanan kaynak fikstürlerinin robotik kaynak teknolojisinin sağladığı avantajların üretim sürecine etkin şekilde aktarılmasında önemli bir proses elemanı olduğu sonucuna varılmıştır.
Anahtar kelimeler: Robotik kaynak, kaynak fikstürü, ürün standardizasyonu, üretim tekrarlanabilirliği, proses verimliliği, kaynaklı imalat.

ABSTRACT
Ensuring quality, continuity, and efficiency in production processes is of great importance, particularly in terms of product standardization in welded manufacturing applications. Robotic welding systems enable the welding process to be carried out in a more controlled manner by allowing welding speed, welding points, and process parameters to be predefined and repeated throughout production cycles. However, the high positioning and repeatability accuracy of the robotic system alone is not sufficient to ensure that product geometry and dimensional characteristics are maintained consistently in each production cycle. The parts to be welded must be positioned according to the correct reference points and kept fixed throughout the welding process. In this study, the advantages and limitations of robotic welding systems in production, as well as the effects of welding fixtures on product standardization,

dimensional repeatability, and process efficiency, were evaluated. In addition, the development and application processes of welding fixtures designed and manufactured within the Nitrocare R&D Center were examined. As a result of the evaluations, it was observed that welding fixtures contribute to maintaining product geometry and ensuring dimensional repeatability between production cycles by enabling the correct referencing, positioning, and fixation of parts. Furthermore, it was determined that product geometry, welding sequence, robot movements, operator ergonomics, production volume, and quality requirements should be considered together in fixture design. Consequently, it was concluded that product standardization in robotic welding processes does not depend solely on the accuracy of the robotic system; rather, the robot, product, welding parameters, and welding fixture should be considered as an integrated system. Properly designed and validated welding fixtures were concluded to be an important process element in effectively transferring the advantages provided by robotic welding technology to the production process.

Keywords: Robotic welding, welding fixture, product standardization, production repeatability, process efficiency, welded manufacturing.

INTRODUCTION

Increasing competition in today's manufacturing industry is driving enterprises toward the goals of higher quality, shorter production times, lower costs, and repeatable production. Particularly in welded manufacturing processes, variations in product quality depending on operator experience, differences in production times, and geometric deviations that may occur during welding increase the importance of process control and automation. The use of industrial robots in welding applications provides significant advantages in terms of the programmability of welding movements, the controllability of process parameters, and the ability to perform the same production cycle with high repeatability (Pires et al., 2006; Ogbemhe & Mpofu, 2015). Developments in robotic arc welding technologies are not limited solely to the automation of robot movements; rather, they are progressing toward more controlled and flexible production systems through the integration of technologies such as sensor systems, image processing, adaptive control, and intelligent process control (Xu et al., 2015; Ogbemhe & Mpofu, 2015). In robotic welding systems, the positioning and repeatability accuracy of the robot manipulator is one of the fundamental parameters affecting process performance. In industrial robots, repeatability refers to the extent to which the robot can repeatedly reach a programmed position in successive cycles and is particularly important in processes such as welding that require precise trajectory tracking. However, the high positioning and repeatability accuracy of the robot alone does not guarantee the dimensional accuracy and geometric repeatability of the welded product. Variations in the geometry of the parts to be welded, manufacturing tolerances, thermal effects occurring during welding, and differences in the positioning of parts on the fixture may cause deviations between the welding path followed by the robot and the actual joint line (Pires et al., 2006; Xu et al., 2015).

Therefore, in robotic welding processes, it is of great importance that the parts are positioned according to the same reference points in each production cycle and maintained in the specified position throughout the welding process. Fixtures are important production equipment used to accurately position, support, and secure workpieces during manufacturing operations (Hargrove & Kusiak, 1994; Cecil, 2001). Fixture design is not limited solely to holding the workpiece but may also have a direct impact on product quality, production efficiency, process reliability, and manufacturing costs (Wang et al., 2010). Boyle et al. (2011) stated that fixtures play an important role in enabling products to be manufactured in accordance with design requirements by ensuring the accurate and secure positioning of workpieces. The primary purpose of welding fixtures is to ensure that the parts to be joined are correctly positioned relative to one another and to defined reference points, and to maintain this position until the welding process is completed. Correct positioning of the workpiece and appropriate restriction of its degrees of freedom are among the fundamental requirements for achieving dimensional accuracy in manufacturing processes (Hargrove & Kusiak, 1994; Wang et al., 2010). In this context, the appropriate determination of locators, support elements, and clamping points in fixture design is important in terms of workpiece stability, geometric accuracy, and the control of deformations that may occur during the process (Cecil, 2001; Boyle et al., 2011).

Particularly in the production of deformation-sensitive components, fixture layout and clamping conditions may have a determining effect on the final product geometry. Lu and Zhao (2015)

demonstrated that optimizing fixture layout in the fixturing of deformable sheet metal workpieces is important for the geometric accuracy of the part. This issue becomes even more important in welded manufacturing because localized heat input occurring during welding may generate residual stresses and dimensional deformations as a result of non-uniform heating and cooling. Therefore, it is not sufficient to consider a welding fixture merely as auxiliary equipment that holds parts in a specific position. Fixture design should be carried out by also considering the thermal and mechanical effects generated by the welding process.

In fixture design, the appropriate selection of clamping points and clamping forces is as important as the correct determination of reference points. Excessive or inappropriate clamping forces may cause undesirable deformation of the workpiece, whereas insufficient clamping may lead to movement of the part during the process and deterioration of positional accuracy. Therefore, it is recommended that fixture design be carried out by considering part geometry, manufacturing tolerances, and process requirements together (Wang et al., 2010; Boyle et al., 2011).

Another important consideration in fixture design for robotic welding applications is robot accessibility. Fixture elements should not restrict the movement range of the welding torch, should allow the robot to access the required welding regions at appropriate angles and distances, and should simultaneously secure the workpieces with sufficient rigidity. This transforms fixture design from merely a mechanical clamping problem into a multi-parameter design problem in which robot movements, welding path, product geometry, and production sequence must be considered together. Hajduk et al. (2009) demonstrated that a modular approach to fixture design for robotic spot-welding applications is important in terms of adapting to different production requirements.

Increasing product variety and variability in production volumes also create new requirements for fixture design. Although conventional product-specific fixtures can provide high accuracy and repeatability, they may have disadvantages such as design and manufacturing costs, preparation time, the need for modifications following product revisions, and storage requirements (Boyle et al., 2011). Therefore, the development of flexible, modular, and reconfigurable fixture systems has become an important research area in the literature. Shirinzadeh (1993) stated that reconfigurable fixture modules can provide significant advantages in terms of adaptability to different production conditions. Similarly, studies on flexible fixture design indicate that the ability of production systems to adapt more rapidly to changing product geometries can contribute to manufacturing flexibility (Gothwal & Raj, 2017).

One of the fundamental issues in fixture design is maintaining product geometry throughout production cycles. Minor variations in fixture layout or inappropriate positioning and clamping points may alter the geometric position of the part and consequently cause product dimensions to fall outside tolerance limits. Therefore, fixture design should be considered not only in terms of securing the part but also in terms of ensuring the dimensional repeatability of the process (Wang et al., 2010; Lu & Zhao, 2015). Particularly in robotic welding applications, since the robot repeats the programmed welding path in the same manner, it is critically important that the workpiece be positioned according to the same coordinate system in every production cycle.

From the perspective of robotic welding systems, transferring the robot's high repeatability accuracy to the product is possible only when the parts are positioned in a repeatable manner compatible with the robot coordinate system. Therefore, the robotic welding system and the welding fixture should not be considered as two independent production elements. The welding fixture is one of the complementary elements of the process that enables the robot's programmed welding path to be applied at the correct position on the actual workpiece. Although sensor and adaptive control technologies in robotic welding systems can compensate for certain variations in the part and welding line, the accurate and repeatable determination of the initial position of the part remains important for process stability (Ogbemhe & Mpofu, 2015; Xu et al., 2015).

Nevertheless, the use of welding fixtures also involves certain technical and economic limitations. The initial design and manufacturing costs of product-specific fixtures, the need for revisions following product changes, maintenance and periodic inspection requirements, and the storage space they require within the production area can be considered among these limitations. Therefore, fixture design should not be carried out solely from the perspective of securing the part; rather, product geometry, production volume, welding sequence, robot movements, operator ergonomics, maintenance requirements, and quality criteria should be considered together (Cecil, 2001; Boyle et al., 2011; Gothwal & Raj, 2017).

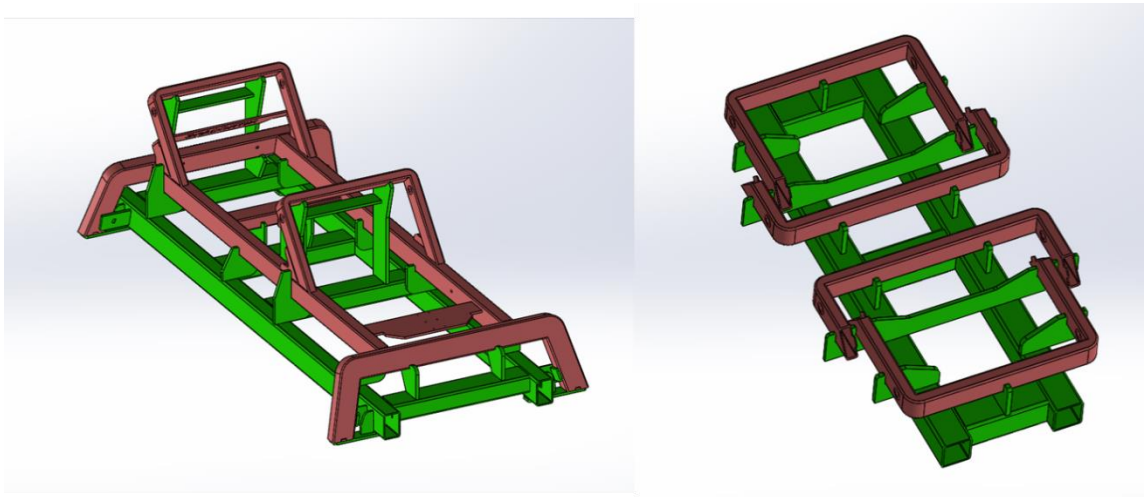
In this study, the advantages provided by robotic welding systems in welded manufacturing processes and the factors that should be considered in practice were addressed, and the role of welding fixtures in product standardization, dimensional repeatability, and process efficiency was investigated. In addition, welding fixtures designed and manufactured within the Nitrocare R&D Center for the robotic welding processes of different products were evaluated through practical application examples. Particular emphasis was placed on the effects of correct referencing, positioning, and securing of parts throughout the welding process on maintaining product geometry. Thus, the study aimed to evaluate the robotic welding system and welding fixture as complementary process components in achieving repeatable and standardized production.

METHOD

This study was conducted as an applied industrial study aimed at evaluating the role of welding fixtures used in robotic welding applications in product standardization, production repeatability, and process efficiency. Within the scope of the study, the robotic welding system used in the production processes of the Nitrocare R&D Center, operating under Gökler Group, and the welding fixtures designed and manufactured in-house for this system were examined.

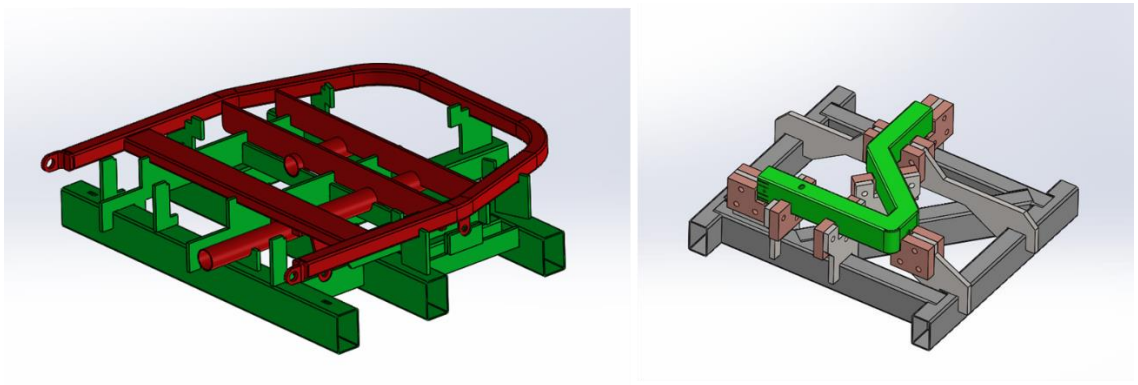
The methodological approach of the study consisted of the following stages: evaluation of the product and welding process, determination of fixture requirements, identification of referencing and clamping points, design and manufacture of the fixture, positioning of the parts on the fixture, and evaluation of their applications in the robotic welding process.

Evaluation of the Product and Welding Process



In the first stage, the geometric structure and welding regions of the products to be subjected to robotic welding were evaluated. In order to ensure that the parts were maintained in the correct position during the robotic welding process, product geometry, the relationships between the parts, the regions to be welded, and the robot's accessibility to these regions were taken into consideration. Based on these evaluations, a fixturing approach was determined to ensure that the parts could be positioned in the same location during each production cycle.

The fundamental approach in fixture design was to position the workpieces according to a repeatable reference system so that the robot could perform the programmed welding motion under the same conditions in each production cycle.



Determination of Referencing and Clamping Points

Product geometry was taken as the basis for determining the positions of the parts to be welded on the fixture. Appropriate reference points were determined to ensure that the parts could be positioned in the same location during each production cycle, and clamping regions were established to prevent movement of the parts during the welding process.

When determining the referencing and clamping points, maintaining the correct geometric relationship between the parts, ensuring accessibility to the welding regions, and preventing fixture elements from interfering with robot movements were taken into consideration. Thus, the fixture was intended to be used not merely as a device for securing the parts, but as a process element contributing to the preservation of product geometry throughout the welding process.

Ürün – Fikstür – Referanslama/Sabitleme

Ürün – Fikstür – Referanslama/Sabitleme

Design and Manufacturing of Welding Fixtures

The welding fixtures were designed in accordance with the determined product geometry, reference points, and clamping requirements. During the design process, the placement and removal of parts from the fixture, accessibility to the welding regions, the robot's range of motion, and the operating conditions within the production process were taken into consideration.

The designed fixtures were manufactured in-house and integrated into the robotic welding process. Following manufacturing, the product components were positioned on the fixtures, and the ability of the referencing and clamping elements to maintain the parts in the desired position was evaluated during application.

Robotic Welding Application

The parts positioned on the fixture were subjected to welding using the robotic welding system. In the robotic welding application, the same welding program was applied throughout the production cycles, enabled by the predefined welding speed, welding points, and process parameters.

At this stage, the primary function of the fixture was to ensure that the parts were positioned in accordance with the robot's programmed welding coordinates and that this position was maintained throughout the welding process. Thus, it was aimed to integrate the robot's repeatability accuracy with the positioning and clamping functions of the fixture within the production process.

Evaluation of Fixtures in Terms of the Production Process

The welding fixtures developed in-house were evaluated in terms of product standardization, dimensional repeatability, process efficiency, and quality consistency. In addition, the design and manufacturing requirements that should be considered in fixture applications were addressed.

The evaluation particularly focused on positioning the parts according to the same references in each production cycle, maintaining product geometry throughout the welding process, ensuring continued robot accessibility to the welding regions, and carrying out the production process in a repeatable manner. In addition, the need for product-specific fixture design, the determination of appropriate reference and clamping points, the control of manufacturing tolerances, the need for fixture modifications following product revisions, and the operating conditions of the fixtures within the production environment were also taken into consideration.

In accordance with this methodology, the interaction between the robotic welding system and the welding fixture within the production process was examined, and the contribution of fixture use to the standardization of the robotic welding process was evaluated through practical application examples.

RESEARCH FINDINGS AND DISCUSSION

Within the scope of the study, welding fixtures used in robotic welding processes and designed and manufactured in-house at the Nitrocare R&D Center were evaluated in terms of product standardization, dimensional repeatability, process efficiency, and quality consistency. The applications demonstrated that, in order to effectively transfer the high repeatability capability of the robotic welding system to the production process, it is important to position the parts according to the same reference points in each production cycle and to keep them fixed throughout the welding process. The robot's ability to repeat the same welding program with high accuracy alone is not sufficient to maintain product geometry and dimensional consistency when variations occur in the positioning of the parts. Therefore, the repeatability accuracy of the robot and the positioning and clamping functions of the fixture were considered complementary elements.

The welding fixtures examined were found to contribute to positioning the parts according to predefined references and maintaining their positions throughout the welding process. Thus, the combined application of a standardized welding program and standardized part positioning becomes possible in the robotic welding process, supporting the preservation of product geometry between production cycles. This assessment is consistent with studies in the literature emphasizing the importance of fixture design for product quality, manufacturing accuracy, and process efficiency (Hargrove & Kusiak, 1994; Wang et al., 2010; Boyle et al., 2011). Similarly, Lu and Zhao (2015) demonstrated that fixture layout has significant effects on the geometric accuracy of workpieces, particularly those susceptible to deformation.

The ability of fixtures to facilitate the positioning of parts according to defined reference points during production cycles also contributes to a more systematic and controlled production process. Rather than determining the position of the part based on operator judgment in each cycle, the use of predefined referencing and clamping elements supports the reduction of operator-related variability. From this perspective, welding fixtures should be regarded not merely as auxiliary equipment for securing parts but as production elements that support the standardization and quality consistency of the robotic welding process (Cecil, 2001; Ogbemhe & Mpofu, 2015).

However, product geometry, the determination of appropriate reference and clamping points, manufacturing tolerances, and robot accessibility should be considered together in fixture design. While fixture elements must provide sufficient clamping of the part, they should not restrict the movement of the robotic welding torch or its access to the welding regions. Furthermore, the design and manufacturing costs of product-specific fixtures, the need for modifications following product revisions, periodic inspection and maintenance requirements, and storage requirements should also be taken into consideration. Therefore, modular and reconfigurable fixture approaches may offer advantages in production systems characterized by high product variety (Hajduk et al., 2009; Gothwal & Raj, 2017).

Overall, the findings of this study indicate that product standardization and repeatability in robotic welding processes do not depend solely on the accuracy of the robotic system; rather, the robot, workpiece, welding parameters, and welding fixture should be evaluated through an integrated approach. Properly designed welding fixtures that are appropriately implemented within the production process were considered important complementary components of robotic welding systems in terms of accurate positioning and clamping of parts, preservation of product geometry, dimensional repeatability, and process efficiency.

CONCLUSION

In this study, the role of welding fixtures used in robotic welding systems in product standardization, dimensional repeatability, and process efficiency was evaluated. As a result of examining the application processes of welding fixtures designed and manufactured within the Nitrocare R&D Center, it was observed that the high positioning and repeatability accuracy of the robotic welding system alone is not sufficient to achieve standardized production; rather, it is important that the parts be positioned according to the correct references in each production cycle and maintained in a fixed position throughout the welding process.

Welding fixtures were considered an important component of the production process not only for the accurate positioning and clamping of parts but also for preserving product geometry, supporting dimensional consistency between production cycles, and reducing operator-related variability. Furthermore, it was concluded that product geometry, reference and clamping points, welding sequence, robot accessibility, operator ergonomics, production volume, and quality requirements should be considered together in fixture design.

In conclusion, in order to establish a repeatable and standardized production structure in robotic welding applications, the robot, workpiece, welding parameters, and welding fixture should be considered through an integrated approach. Properly designed welding fixtures that are appropriately implemented within the production process are expected to contribute to the more effective transfer of the advantages provided by robotic welding technology to production and to the establishment of a sustainable quality standard.

Abstract
This work examines how incident optical power density governs the photoresponse characteristics of a doped graphene quantum dot-based heterojunction over the 20-100 mW/cm^2 range. Current-voltage measurements were performed over a bias range of -2.5 to +1.5 V under dark conditions and at five different illumination intensities. At -2.5 V, the dark current was approximately 9.48 µA, while illumination resulted in a pronounced enhancement of the device current. The power-dependent photodetection behavior was further evaluated through sensitivity, responsivity, external quantum efficiency (EQE), and specific detectivity (D*). As the incident power density increased from 20 to 100 mW/cm^2, the sensitivity increased from 9.91 to 29.34. In contrast, the responsivity exhibited an overall decrease from 0.598 to 0.354 A/W. A similar trend was observed for EQE and D*, which changed from 134.8% to 79.8% and from 3.04 × 10^{10} to 1.80 × 10^{10} Jones, respectively. The highest responsivity, EQE, and detectivity were therefore achieved at 20 mW/cm^2, whereas higher illumination levels produced greater sensitivity. The different intensity-dependent trends observed in these performance parameters suggest that increasing photon flux affects the balance among carrier generation, interfacial trapping, trap filling, and recombination processes. Overall, the results demonstrate that the photodetection characteristics of the heterojunction are strongly dependent on incident optical power density and provide insight into the underlying intensity-dependent carrier dynamics.
Keywords: Doped graphene quantum dots, heterojunction, incident optical power density, photodetector performance

Özet
Bu çalışmada, 20-100 mW/cm² aralığındaki ışık şiddetinin katkılı grafen kuantum nokta tabanlı bir heteroeklemin fotocevap özellikleri üzerindeki etkisi incelenmiştir. Akım-gerilim ölçümleri, -2,5 ile +1,5 V gerilim aralığında, karanlık koşullarda ve beş farklı ışık şiddeti altında gerçekleştirilmiştir. -2,5 V'ta karanlık akım yaklaşık 9,48 µA olarak belirlenirken, aydınlatma altında aygıt akımında belirgin bir artış gözlenmiştir. Optik güce bağlı fotodedeksiyon davranışı; duyarlılık, responsivite, dış kuantum verimi (EQE) ve özgül dedektivite (D*) parametreleri üzerinden ayrıca değerlendirilmiştir. Gelen optik güç yoğunluğu 20 mW/cm2'den 100 mW/cm^2'ye artırıldığında duyarlılık 9,91'den 29,34'e yükselmiştir. Buna karşılık responsivite genel olarak azalarak 0,598 A/W'den 0,354 A/W'ye düşmüştür. Benzer bir eğilim EQE ve D* için de gözlenmiş ve bu değerler sırasıyla %134,8'den %79,8'e ve 3,04 × 10^{10} Jones değerinden 1,80 × 10^{10} Jones değerine değişmiştir. En yüksek responsivite, EQE ve dedektivite değerleri 20 mW/cm^2'de elde edilirken, daha yüksek ışık şiddetlerinde daha yüksek duyarlılık gözlenmiştir. Bu performans parametrelerinde gözlenen ışık şiddetine bağlı farklı eğilimler, artan foton akısının taşıyıcı üretimi, arayüzey tuzaklanması, tuzak durumlarının dolması ve rekombinasyon süreçleri arasındaki dengeyi etkilediğine işaret etmektedir. Genel olarak sonuçlar, heteroeklemin fotodedeksiyon özelliklerinin gelen optik güç yoğunluğuna güçlü biçimde bağlı olduğunu göstermekte ve ışık şiddetine bağlı temel taşıyıcı dinamiklerinin anlaşılmasına katkı sağlamaktadır.
Anahtar kelimeler: Katkılı grafen kuantum noktaları, heteroeklem, ışık şiddeti, fotodedektör performansı

GİRİŞ

Kuantum noktaları, nanometre ölçeğinde yarı iletken parçacıklardır ve bu nedenle nanokristaller olarak da adlandırılırlar. Kuantum noktalarının (QD'ler) eksitonları üç boyutta sınırlandırıldığından, QD'ler benzersiz optik ve elektriksel özellikler sergilerler. QD'lerin en önemli özelliği kuantum sınırlama etkisidir. QD'lerin boyutları Bohr yarıçapından daha küçük hale geldikçe, sürekli enerji seviyeleri kuantize olmaya başlar. Bu ilkeye göre, enerji seviyesi değeri QD'lerin boyutuna göre ayarlanabilir. Kuantum noktalarının boyutunun küçültülmesi, enerji bant aralığının artmasına yol açar; dolayısıyla emisyon ve absorpsiyon tepe noktalarında maviye kayma meydana gelir. Bu durumda, sentez sırasında reaksiyon sıcaklığı, süresi, öncü madde, ligand vb. yoluyla kuantum noktalarının boyutlarının kontrol edilmesi suretiyle, belirli emisyon ve absorpsiyon özelliklerine sahip kuantum noktalarının tasarımı gerçekleştirilebilir.Kuantum noktalarının bu benzersiz özellikleri, optik ve elektronik cihazlardaki uygulamalar için büyük bir potansiyel sunmaktadır(Wang et al. 2023).

Grafen kuantum noktası (GQD), nanokarbon malzemeleri ailesinin en yeni üyesidir. Genellikle 10 nm'den küçük yanal boyutlara sahip, atomik incelikte bir grafitik düzleme (genellikle 1 veya 2 tabaka, <2 nm kalınlığında) sahip, sıfır boyutlu (0D) bir grafen malzemesidir. İki boyutlu (2D) muadili olan grafen tabakasıyla karşılaştırıldığında GQD; kuantum sınırlamasından kaynaklanan bant aralığı ayarlanması, mükemmel dağılabilirlik, daha bol aktif bölgeler (kenarlar, fonksiyonel gruplar, katkı atomları vb.) özelliklere sahip olmasıyla, daha verimli, hızlı, esnek ve gelişmiş performansa sahip elektronik cihazların geliştirilmesine katkıda bulunabilir(Yan et al. 2019).

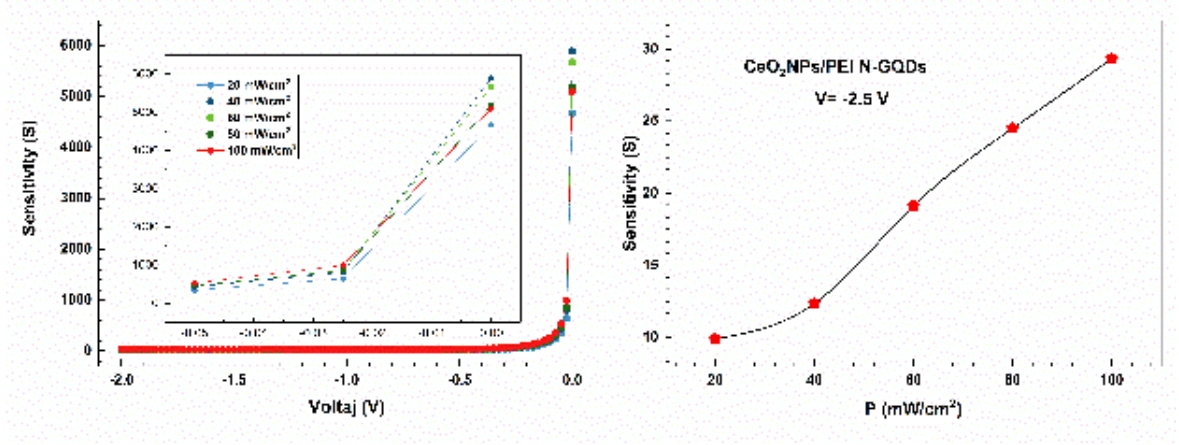
Seryumoksit (CeO_2), 3,2–3,6 eV bant aralığına sahip bir lantanit üyesidir. Optoelektronik uygulamalar için olağanüstü özellikler sergileyerek model bir metal oksit olarak seçilmiştir(Zhang et al. 2025).

Nadir toprak oksidi CeO_2, güçlü UV emilimi, olağanüstü termal ve kimyasal kararlılık, yüksek elektrik iletkenliği ve düşük maliyet sunarak, kendi kendine çalışan (self-powered) UV fotodedektörleri (UVPD) için ideal bir aday haline gelmektedir. CeO_2 temel bir özelliği, seryum iyonlarının Ce^{+3} ve Ce^{+4} olmak üzere iki yükseltgenme basamağında bir arada bulunmasıdır; bu durum elektron transfer verimliliğini artırır ve UV bölgesindeki ışık emilimini güçlendirir. Ayrıca, CeO_2 yüksek konsantrasyonda içsel oksijen boşlukları (OV'ler) içerir; bu boşluklar, elektron verici olarak işlev görerek yük taşınımını iyileştirir ve taşıyıcı ömürlerini uzatır. Bu avantajlı özellikleri sayesinde CeO_2, son zamanlarda kendi gücünü üreten UVPD uygulamaları için yoğun ilgi görmektedir. Li ve ark. van der Waals heteroyapıları üretmek için hidrotermal aşağıdan yukarıya birleştirme yöntemini kullanmışlardır; bu yapılar, 1D CeO_2 ile 0D bizmut kuantum noktalarının entegre edilmesiyle oluşturulmuştur. Elde edilen yapı, 1,0 M KOH çözeltisinde kararlı bir fototepki sergilemiştir. Huang ve ark. piezoelektrik ve piezo-fototronik etkiler sergileyen polidopamin kaplı seryum oksit (CeO_2@PDA) nanopartikülleri ve poli(viniliden florür) (PVDF) nanofiber tekstiller hakkında bildirimde bulunmuştur. Bununla birlikte, bu kompozit bazlı PD, 10 mW cm^{-2} ışık yoğunluğu altında sadece $5{,}21 \times 10^5$ Jones'luk bir algılama hassasiyeti elde etmiştir ki bu değer nispeten düşüktür. Bu sınırlama, muhtemelen PVDF matrisinin düşük iletkenliğinden ve CeO_2@PDA nanopartiküllerinin homojen olmayan dağılımından kaynaklanmaktadır; her ikisi de verimli yük taşınımını engellemektedir(Huang et al. 2025).

Bu çalışmada, GQD'lerin optoelektronik performansını geliştirmek amacıyla CeO_2 nanopartikülleri ile oluşturulan CeO_2NP/PEI-N-GQD nanokompozitleri çevre dostu hidretermal işlemle sentezlendi. -2,5 ile +1,5 V gerilim aralığında, karanlık koşullarda ve beş farklı ışık şiddeti altında hassasiyet (S), foto-cevap (R), detektivite (D*) ve dış kuantum verimliliği (EQE) parametreleri incelenerek fotodetektör özellikleri incelenmiştir.

YÖNTEM

CeO_2NP/PEI-N-GQD nanokompozit yapının sentezlenmesinde İki adım var. İlk olarak PEI-N-GQD sentezi belirlenen miktarlardaki sitrik asit (CA) ve polietilenimin (PEI), deiyonize su içerisinde tamamen çözülmüştür. Homojen çözelti otoklava aktarılmış ve hidrotermal işleme tabi tutulmuştur. İkinci aşamada hazırlanan süspansiyona, önceden deiyonize suda çözülmüş $Ce(NO_3)_3 \cdot 6H_2OCe(NO_3)_3 \cdot 6H_2$ öncül çözeltisi ilave edilerek Hidrotermal işlem sonucunda CeO_2NP/PEI-N-GQD nanokompozitleri elde edilmiştir. Dedektör yapısı, ilk olarak, Altın omik kontak n tipi si levha üzerine fiziksel buhar biriktirme yoluyla biriktirildi. Daha sonra Sentezlenen CeO_2NPs/PEI N-GQDs çözeltileri, n tipi Si levha üzerine spin coating olarak kaplandı. Son olarak, metal bir gölge maskesi kullanılarak PVD yöntemiyle nanokompozit tabaka üzerine dairesel Altın kontaklar oluşturuldu. Uygulanan bu adımların ardından CeO_2NP/PEI-N-GQD heteroyapılı dedektör yapısı elde edilmiştir.



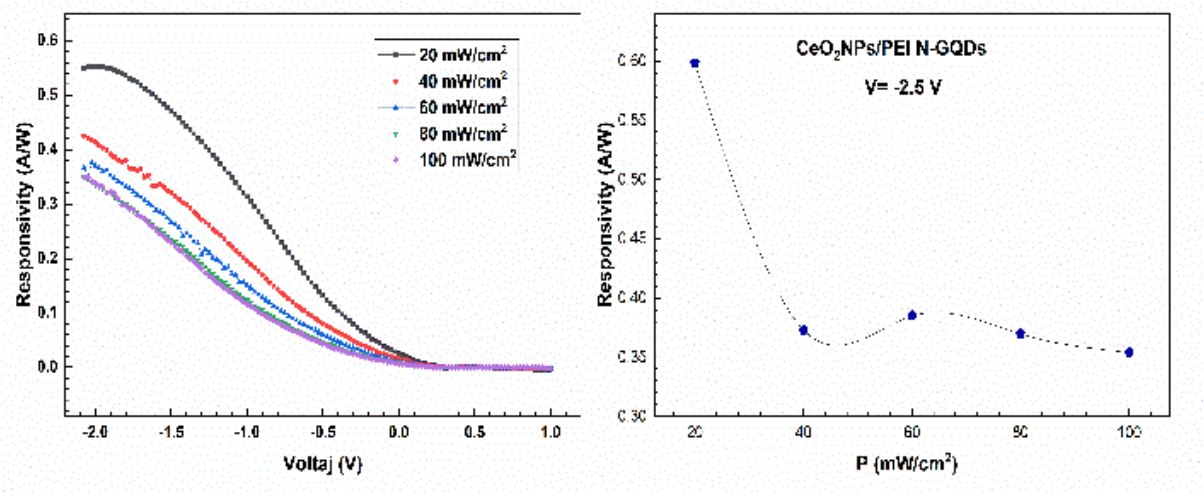
ARAŞTIRMA BULGULARI VE TARTIŞMA

Tablo1. de sentezlenen katkılı grafen kuantum nokta tabanlı bir heteroeklemin 20 ve 100 mW/cm² ışık şiddetlerindeki fotodedektör verileri incelenmiştir. Hibrit yapı, 20 mW/cm² optik güç yoğunluğunda daha yüksek kuantum verimi %134, responsivity 0.598A/W ve dedektivite 3,04 × 10^{10} Jones sergilerken; 100 mW/cm² yüksek güç yoğunluğunda taşıyıcı rekombinasyonu ve doyum etkileri nedeniyle bu parametrelerde düşüş, buna karşın toplam fotoakım artışına bağlı olarak hassasiyette 29.34 belirgin bir yükseliş göstermektedir.

Tablo 1. CeO_2NPs/PEI N-GQDs Heteroeklemin Fotodedektör Performansı

Işık Gücü	Sensitivity (S)	Responsivity (R) A/W	Dedektivity (D^*) Jones	EQE %
20 mW/cm^2	9.91	0,598 A/W	3,04 × 10^{10} Jones	%134,8
1000 mW/cm^2	29.34	0,354 A/W	1,80 × 10^{10}Jones	%79,8

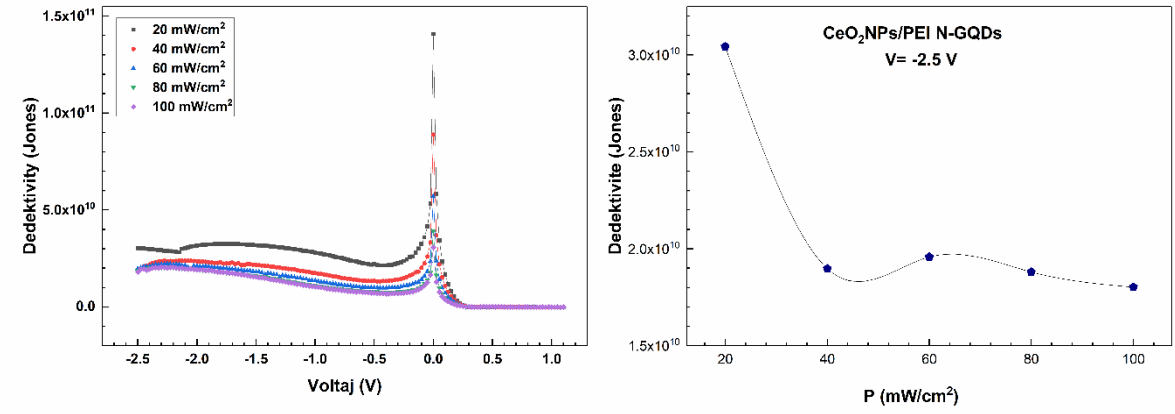
CeO_2NPs/PEI N-GQDs heteroeklemin voltaja karşı hassasiyet (sensitivity) ve -2.5 V'da ışık gücüne bağlı sensitivity değişimi grafiği Şekil 1'de verilmiştir. Grafik incelendiğinde, hibrit yapının -2 V ila -0,5 V potansiyel aralığında neredeyse sabit kaldığı ve yalnızca ihmal edilebilir dalgalanmalar sergilediği anlaşılmaktadır. Ancak voltaj 0 V'a yaklaştıkça hassasiyette ani ve belirgin bir artış meydana gelmiştir. Bu hızlı yükseliş, hibrit yapının düşük bias altında fotodeteksiyon performansının önemli ölçüde iyileştiğini ve özellikle 0 V civarında yüksek hassasiyet sergilediğini göstermektedir. Optik güç yoğunluğu 20 mW/cm^2'den 100 mW/cm^{2}ye çıktıkça duyarlılık değeri yaklaşık 9.9'dan başlayarak yaklaşık 29.4'e kadar düzenli ve belirgin bir şekilde artmaktadır. Bu durum, artan foton akısının aktif alanda daha fazla elektron-deşik çifti (fototaşıyıcı) üretmesiyle ilişkilendirilebilir.



(a) (b)

Şekil 1. Ce katkılı PEI N-GQDs foto diyotların a) voltaja karşı hassasiyet grafiği b) ışık gücüne bağlı sensitivity değişimi grafiği

Şekil 2'de, farklı optik güç yoğunlukları 20 – 100 mW/cm^2 altında fotodedektörün Responsivity, uygulanan voltaja (-2.0V ile +1.0 V aralığı) bağlı değişimini göstermektedir. Ters besleme geriliminin 0 V'tan -2.0 V'a çıkarılmasıyla responsivitede keskin bir artış gözlenmiştir. Ters bias altında genişleyen tükenim bölgesi ve güçlenen dahili elektrik alan, fototaşıyıcıların sürüklenme hızını artırarak elektron-deşik çiftlerinin rekombinasyona uğramadan toplanmasını kolaylaştırmaktadır. İleri besleme bölgesinde V > 0.2 V ise arayüz bariyerinin zayıflaması nedeniyle foto-akım toplanması engellenmiş ve responsivite sıfıra yaklaşmıştır. Aygıtın responsivitesi, en düşük güç yoğunluğu olan 20 mW/cm^2'de maksimum yaklaşık olarak 0.60A/W değerine ulaşmış, artan ışık gücüyle birlikte azalarak 100 mW/cm^2'de yaklaşık 0.35 A/W seviyesine gerilemiştir. Responsivitenin artan güç yoğunluğu ile

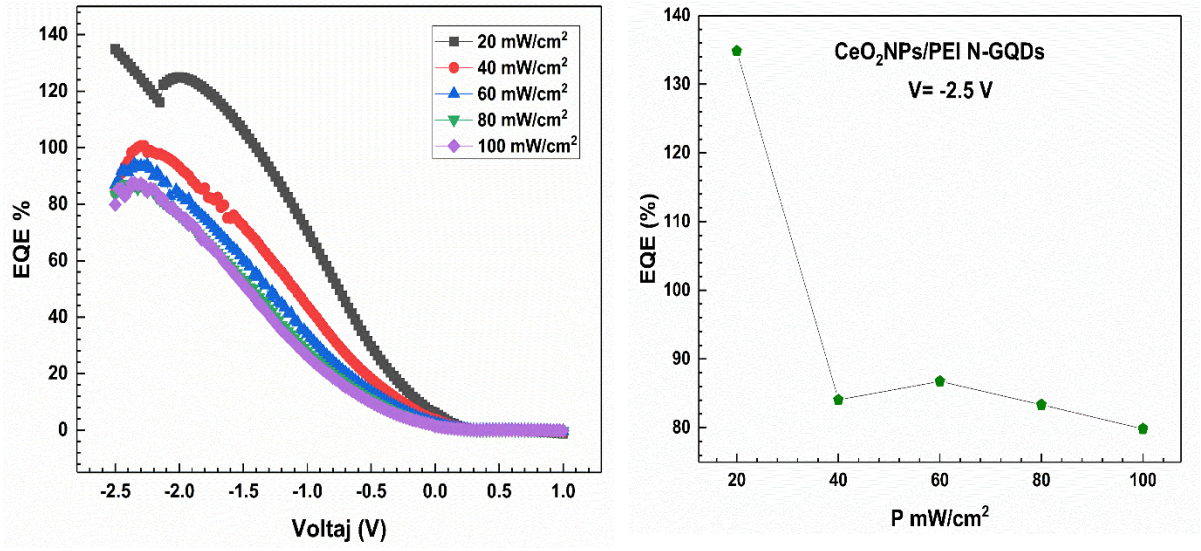


sergilediği bu ters orantılı davranış, fotodedektörlerde sıklıkla gözlenen foto-taşıyıcı tuzaklama ve rekombinasyon kinetiği ile açıklanmaktadır.

(a) **(b)**

Şekil 2. Ce katkılı PEI N-GQDs foto diyotların**.** (a) voltaja karşı foto-cevap grafiği, (b) ışık gücüne bağlı foto-cevap değişimi grafiği

Şekil 3'te D^* parametresinin, uygulanan gerilim ve farklı optik güç yoğunluklarına bağlı değişimi incelenmiştir. Grafiğin en dikkat çekici özelliği, uygulanan ışık gücü arttıkça algılama değerinde görülen sürekli ve güçlü artıştır. Elde edilen eğriler, sıfır gerilim 0V civarında dedektivitede keskin bir rezonans benzeri artış ortaya koymaktadır. En düşük optik güç yoğunluğunda maksimum tepe değerine ulaşmaktadır. Bu keskin pik, sıfır-bias bölgesinde termal ve tünelleme kaynaklı karanlık akımın minimuma inmesiyle gürültü seviyesinin dramatik biçimde bastırılmasından kaynaklanmaktadır. Bu sonuç, nanokompozit yapının harici bir güç beslemesine gereksinim duymaksızın yüksek hassasiyetli bir kendi kendine çalışan (self powered) fotodedektör olarak çalışabildiğini kanıtlamaktadır. Aygıtın dedektivitesi 20 mW/cm2 de en yüksek değeri olan yaklaşık 3.05 x1010Jones seviyesine ulaşmış, artan ışık şiddetiyle azalarak 100 mW/cm2'de 1.80x1010 Jones değerine gerilemiştir.



(a) (b)

Şekil 3. Ce katkılı PEI N-GQDs foto diyotların (a) voltaja karşı dedektivite grafiği (b) güce karşı dedektivite grafiği

Şekil 4'te, farklı optik güç yoğunlukları altında aygıtın Harici Kuantum Veriminin uygulanan gerilime bağlı değişimini göstermektedir. Ters besleme geriliminin artmasıyla birlikte güçlü elektrik alanın taşıyıcı ayrışmasını kolaylaştırması sonucunda EQE değerlerinde dikkate değer bir yükseliş kaydedilmiştir. En düşük güç yoğunluğunda 20 mW/cm^2'de EQE değeri yaklaşık %135 gibi yüksek bir

seviyeye ulaşarak teorik birlik sınırını aşmıştır. Bu durum, seryum katkısı kaynaklı lokalize kusur seviyelerinin ve oksijen boşluklarının fototaşıyıcı ömrünü uzatmasıyla devreye giren fotoiletken kazanç mekanizması ile açıklanmaktadır.

SONUÇ

Bu çalışmada, CeO_2 katkılı ve PEI ile işlevselleştirilmiş azot katkılı grafen kuantum noktaları sentezlenmiş ve Au/CeO_2NPs/PEI-N-GQDs/n-Si/Au heteroeklem aygıtlarında bir arayüz katmanı olarak kullanılmıştır.

Elde edilen nanokompozitin optoelektronik performansı değerlendirilmiştir. Schotky fotodiyotun farklı ışık yoğunlukları için akım-voltaj ölçümleri yapıldı ve diyot için temel fotodiyot parametreleri sensitivity, responsivity, dedektivity ve EQE değerleri belirlendi.

Üretilen aygıtlar belirgin bir doğrultma davranışı ve aydınlatma altında kayda değer bir foto-yanıt sergilemiş; böylece CeO_2 modifiyeli PEI N-GQDs nanokompozitlerinin, çözelti tabanlı yöntemlerle üretilen silisyum esaslı fotodetektör uygulamaları için potansiyelini ortaya koymuştur. İncelenen fotodiyot parametreleri literatürle karşılaştırıldığında, üretilen hibrit yapının bir fotodiyot olarak iyi performans gösterdiği ve optoelektronik teknolojilerde kullanım için geliştirilebileceği tespit edildi.

Gelecek araştırmalarda; arayüz mühendisliği, farklı katkı konsantrasyonları ve uygun bant hizalanmasının optimize edilmesi yoluyla fotodedeksiyon özelliklerinin geliştirilmesi hedeflenebilir.

ÖZET

Grafen kuantum noktaları (GQD'ler), ayarlanabilir elektronik ve optik özellikleri, yüksek yüzey alanları ve çevre dostu üretime uygunlukları sayesinde optoelektronik uygulamalar açısından önemli bir potansiyele sahiptir. GQD'lerin heteroatomlarla katkılanması, elektronik yapı ve yük taşıma özelliklerinin kontrol edilmesine imkân sağlayarak fotodedektör performansının iyileştirilmesi için etkili bir yaklaşım sunmaktadır. Özellikle bizmut katkısı, GQD tabanlı yapıların elektronik özelliklerinin modüle edilmesi ve fotoindüklenmiş yük taşınımının geliştirilmesi açısından dikkat çekmektedir. Bu çalışmada, bizmut katkılı GQD tabanlı bir heteroeklemin 24 aylık bekletme sonrasındaki fotodedeksiyon performansı incelenmiş ve elde edilen sonuçlar başlangıç fotodedeksiyon karakteristikleriyle karşılaştırılmıştır. Başlangıç ölçümleri 96 mW/cm², 24 ay sonraki ölçümler ise 100 mW/cm² ışık yoğunluğu altında gerçekleştirilmiştir. Fotodedektör performansı; responsivite (R), hassasiyet (S), dış kuantum verimi (EQE) ve spesifik dedektivite (D*) parametreleri kullanılarak değerlendirilmiştir. Başlangıç ölçümlerinde, ışık yoğunluğunun artmasıyla ters akımın sistematik olarak arttığı ve aygıtın belirgin bir fotocevap sergilediği gözlenmiştir. 96 mW/cm² ışık yoğunluğunda ve −4 V'ta R = 0,12 A/W, S = 9 × 10², EQE = %27 ve D* = 5,6 × 10¹⁰ Jones değerleri elde edilmiştir. Yirmi dört ay sonra, 100 mW/cm² ışık yoğunluğu altında gerçekleştirilen ölçümlerde fotodedektörün belirgin bir fotocevap sergilemeye devam ettiği görülmüştür. Bu koşullarda, −4 V'ta R = 0,33 A/W, S = 3,3 × 10², EQE = %74 ve D* = 5,8 × 10¹⁰ Jones değerleri elde edilmiştir. Başlangıç ve 24 ay sonraki ölçümlerin benzer ışık yoğunluklarında gerçekleştirilmiş olması, aygıtın uzun bir bekletme süresi sonrasında fotodedeksiyon davranışının karşılaştırmalı olarak değerlendirilmesine imkân sağlamaktadır. Elde edilen sonuçlar, bizmut katkılı GQD tabanlı heteroeklemin 24 aylık bekletme sonrasında genel fotodedeksiyon işlevselliğini büyük ölçüde koruduğunu göstermektedir.

Anahtar kelimeler: Bizmut katkılı grafen kuantum noktaları, heteroeklem, fotodedektör, fotodedeksiyon performansı, uzun dönem performans.

ABSTRACT

Graphene quantum dots (GQDs) have attracted considerable attention for optoelectronic applications due to their tunable electronic and optical properties, high surface area, and compatibility with environmentally friendly synthesis approaches. Heteroatom doping of GQDs provides an effective strategy for tailoring their electronic structure and charge-transport properties, thereby improving photodetector performance. In particular, bismuth doping offers potential for modulating the electronic properties of GQD-based structures and enhancing photoinduced charge transport. In this study, the photodetection performance of a bismuth-doped GQD-based heterojunction was investigated after a 24-month period and compared with its initial photodetection characteristics. The initial measurements were performed under an illumination intensity of 96 mW/cm², whereas the measurements after 24 months were carried out at 100 mW/cm². Photodetector performance was evaluated in terms of responsivity (R), sensitivity (S), external quantum efficiency (EQE), and specific detectivity (D*). The initial measurements revealed a systematic increase in reverse current with increasing illumination intensity, confirming a pronounced photoresponse of the device. At an illumination intensity of 96 mW/cm² and −4 V, R = 0.12 A/W, S = 9 × 10², EQE = 27%, and D* = 5.6 × 10¹⁰ Jones were obtained.

After 24 months, the measurements performed at 100 mW/cm² showed that the photodetector continued to exhibit a pronounced photoresponse. Under these conditions, R = 0.33 A/W, S = 3.3 × 10², EQE = 74%, and D* = 5.8 × 10¹⁰ Jones were obtained at −4 V. The measurements performed at comparable illumination intensities enable a comparative assessment of the photodetection behavior of the device after an extended period. The results demonstrate that the bismuth-doped GQD-based heterojunction largely retained its overall photodetection functionality after 24 months.
Keywords: Bismuth-doped graphene quantum dots, heterojunction, photodetector, photodetection performance, long-term performance.

GİRİŞ

Fotodedektörler, gelen ışığı elektrik sinyallerine dönüştüren ve optik iletişim, görüntüleme, algılama ve çevresel izleme gibi alanlarda yaygın olarak kullanılan temel optoelektronik cihazlardır. Performansları genellikle responsivite, hassasiyet, spesifik dedektivite ve dış kuantum verimi (EQE) gibi parametreler kullanılarak değerlendirilir. Bu nedenle, verimli fotodedektörlerin geliştirilmesi, etkili fototepki ve güvenilir elektriksel özellikler sağlayan uygun aktif malzemelerin ve cihaz mimarilerinin seçilmesini gerektirir (Sohal, Maity, & Basu, 2021; Zhang, Liu, Gong, Liu, & Chen, 2022).

GQD'ler, ayarlanabilir optik ve elektronik özellikleri, kuantum sınırlama etkileri ve çevre dostu sentez yöntemleriyle üretilebilmeleri nedeniyle optoelektronik uygulamalar açısından ilgi görmektedir. Ayrıca, heteroatom katkılama, kimyasal bileşim ve elektronik durumlarda değişiklikler oluşturarak GQD'lerin elektronik yapısının ve optik tepkisinin modüle edilmesine imkân sağlamaktadır (Im, Kim, Hyeong, Moon, & Bae, 2023). Heteroatom katkılı GQD'lerin heteroeklem yapılarına dahil edilmesi, yük taşınımının kontrol edilmesine ve fotodedeksiyon özelliklerinin geliştirilmesine imkân sağlayabilir. Özellikle GQD tabanlı malzemelere bizmut katkılanması, malzemenin elektronik özelliklerinin modüle edilmesine ve bunun heteroeklemin fototepkisi üzerindeki etkilerinin araştırılmasına imkân sağlamaktadır (Berktaş vd., 2026).

Fotodedektörlerin başlangıç performanslarının yanı sıra, uzun dönemli işlevsel davranışları da potansiyel pratik uygulamaları açısından önemli bir husustur. Zaman içinde akım-gerilim karakteristiklerinde ve fotodedeksiyon parametrelerinde meydana gelen değişiklikler, bir cihazın ışıkla indüklenen elektriksel sinyalleri üretme ve algılama yeteneğini koruyup korumadığı hakkında bilgi sağlayabilir. Bu nedenle, uzun bir bekletme süresi sonrasında fotodedektör karakteristiklerinin incelenmesi, cihazın uzun dönemli davranışının değerlendirilmesi açısından önem taşımaktadır (Kielar, Dhez, Pecastaings, Curutchet, & Hirsch, 2016).

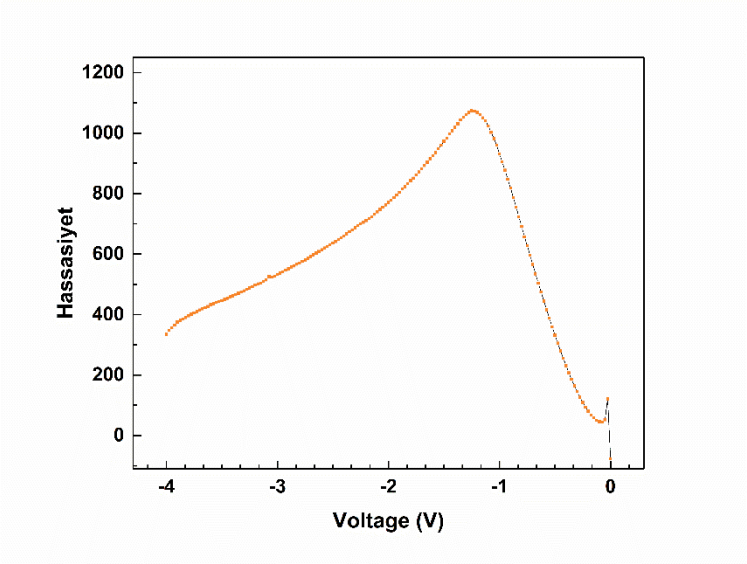
Bu çalışmada, bizmut katkılı GQD tabanlı bir heteroeklemin 24 aylık bekletme sonrasındaki fotodedeksiyon davranışı araştırılmıştır. Başlangıç fotodedeksiyon sonuçları önceki çalışmamızda (Berktaş vd., 2026) raporlanmış olup, bu çalışma cihazın 24 ay sonraki karakterizasyonuna ve başlangıç sonuçlarıyla karşılaştırılmasına odaklanmaktadır. Fotodedeksiyon performansı; responsivite (R), hassasiyet (S), dış kuantum verimi (EQE) ve spesifik dedektivite (D*) parametreleri kullanılarak değerlendirilmiştir. Başlangıç ölçümleri 96 mW/cm² ışık yoğunluğu altında gerçekleştirilirken, 24 ay sonraki ölçümler 100 mW/cm² ışık yoğunluğu altında gerçekleştirilmiştir. Birbirine yakın ışık yoğunluklarında gerçekleştirilen bu ölçümler, cihazın uzun dönemli fotodedeksiyon davranışının karşılaştırmalı olarak değerlendirilmesine imkân sağlamaktadır.

YÖNTEM

Çevre dostu bir sentez yaklaşımı olan hidrotermal yöntem kullanılarak Bi katkılı GQD'ler sentezlenmiştir. Sentez işlemi iki aşamada gerçekleştirilmiştir. İlk aşamada, sitrik asit öncülü kullanılarak yüksek sıcaklık ve basınç altında otoklav içerisinde reaksiyon gerçekleştirilmiş ve GQD'ler elde edilmiştir. İkinci aşamada, bizmut(III) nitrat öncülü ile GQD'lerin sulu çözeltisi otoklav içerisinde 90 °C'de 2 saat süreyle reaksiyona tabi tutulmuş ve Bi katkılı GQD'ler elde edilmiştir.

Bi katkılı GQD'lerin sentezlenmesinin ardından, p-tipi silikon alttaş kullanılarak fotodedektör yapısı oluşturulmuştur. İlk olarak, p-tipi silikon alttaşın alt yüzeyine sputtering yöntemiyle altın (Au) kaplanarak omik kontak oluşturulmuştur. Daha sonra, Bi katkılı GQD'ler spin-coating yöntemiyle p-tipi silikon alttaşın üst yüzeyine kaplanmıştır. Son aşamada, Bi katkılı GQD tabakasının üzerine sputtering yöntemiyle Au kaplanarak doğrultucu kontak oluşturulmuş ve fotodedektör yapısı tamamlanmıştır.

ARAŞTIRMA BULGULARI VE TARTIŞMA



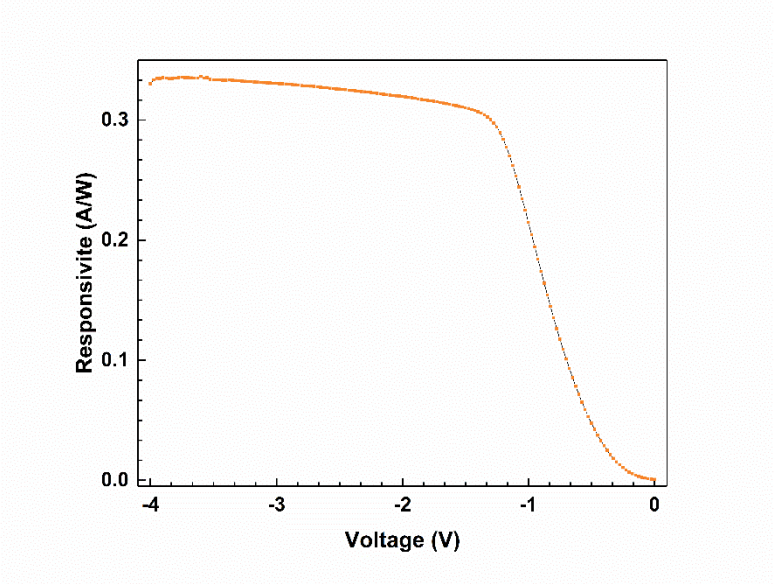
Bu çalışmada, Bi katkılı GQD tabanlı fotodiyotun 24 aylık bekletme sonrasındaki fotodedeksiyon performansı incelenmiş ve elde edilen sonuçlar başlangıç ölçümleriyle karşılaştırılmıştır. Bi katkılı GQD tabanlı heteroeklemin başlangıç fotodedeksiyon özellikleri daha önceki çalışmamızda (Berktaş vd., 2026) raporlanmış olup, bu değerler 24 ay sonra gerçekleştirilen ölçümlerle karşılaştırmada referans olarak kullanılmıştır.

Başlangıç ölçümlerinin ardından cihaz, dış ortamla doğrudan temasını sınırlandıracak şekilde üstü kapalı bir ortamda 24 ay süreyle bekletilmiştir. Bu sürenin sonunda fotodedektör karakterizasyonu yeniden gerçekleştirilmiştir. Başlangıç ve 24 ay sonraki karakterizasyonlar farklı laboratuvarlarda ve farklı ölçüm sistemleri kullanılarak gerçekleştirilmiştir. Başlangıç ölçümleri 96 mW/cm², 24 ay sonraki ölçümler ise 100 mW/cm² ışık yoğunluğu altında gerçekleştirilmiştir. Birbirine yakın ışık yoğunluklarında gerçekleştirilen bu ölçümler, Bi katkılı GQD tabanlı fotodedektörün 24 aylık bekletme sonrasındaki fotodedeksiyon davranışının başlangıç karakteristikleriyle karşılaştırmalı olarak değerlendirilmesine imkân sağlamıştır. Fotodedektör performansı; R, S, EQE ve D* parametreleri kullanılarak değerlendirilmiştir.

Hassasiyet (S), cihazın aydınlatma altında oluşturduğu akım değişiminin karanlık durumdaki akıma göre büyüklüğünü ifade eder ve Denklem (1) kullanılarak hesaplanır:

$$S = \frac{I_{light} - I_{dark}}{I_{dark}} \qquad (1)$$

Burada I_{light} ve I_{dark}, sırasıyla aydınlatılmış ve karanlık koşullarda ölçülen akımlardır. Şekil 1'de hassasiyetin uygulanan gerilime bağlı değişimi verilmiştir. Negatif gerilim bölgesinde hassasiyetin gerilime bağlı olarak belirgin bir değişim gösterdiği ve yaklaşık −1,2 V civarında maksimum değerine ulaştığı görülmektedir. Bu gerilimde hassasiyet yaklaşık 1,1 × 10³ değerine ulaşmaktadır. Maksimum noktanın her iki tarafında hassasiyet azalmakta ve özellikle gerilimin 0 V'a yaklaşmasıyla bu azalma daha belirgin hale gelmektedir. Bu sonuçlar, fotodedektör hassasiyetinin uygulanan gerilime güçlü bir şekilde bağlı olduğunu ve incelenen gerilim aralığında en yüksek hassasiyetin yaklaşık −1,2 V civarında elde edildiğini göstermektedir.



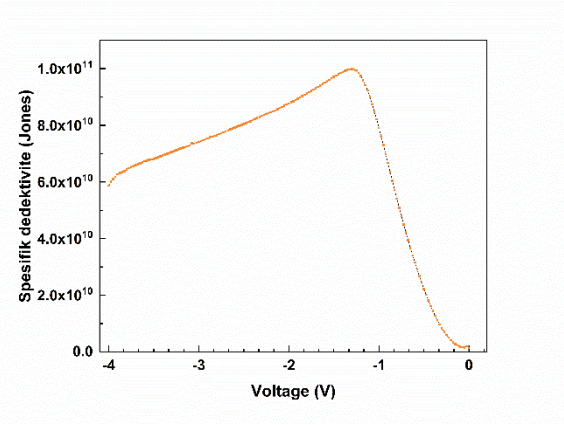
Şekil 1. Bi katkılı GQD hibrit yapının uygulanan gerilime bağlı hassasiyet (S) değişimi.

Responsivite (R), fotodedektör tarafından üretilen fotoakımın gelen optik güce oranını ifade eder ve Denklem (2) kullanılarak hesaplanır:

$$R = \frac{I_{photo}}{P_{opt}} = \frac{I_{light} - I_{dark}}{E_{inc}.A} \qquad (2)$$

Burada I_{photo} fotoakım, E_{inc} gelen ışık yoğunluğu (mW cm^{-2}), A diyot alanı ve P_{opt} gelen optik güçtür. Şekil 2'de responsivitenin uygulanan gerilime bağlı değişimi verilmiştir. Responsivitenin yaklaşık −4 V ile −1,5 V arasındaki negatif gerilim bölgesinde 0,30–0,34 A/W aralığında kaldığı görülmektedir. Gerilimin 0 V'a yaklaşmasıyla responsivite belirgin biçimde azalmakta ve sıfıra yaklaşmaktadır. Bu

sonuçlar, cihazın responsivitesinin yüksek negatif gerilim bölgesinde uygulanan gerilime karşı nispeten kararlı bir davranış sergilediğini göstermektedir.



Şekil 2. Bi katkılı GQD hibrit yapının uygulanan gerilime bağlı responsivite (R) değişimi.

Spesifik dedektivite (D*), fotodedektörün düşük seviyeli optik sinyalleri gürültüden ayırt ederek algılama kabiliyetini ifade eden önemli bir performans parametresidir ve Denklem (3) kullanılarak hesaplanır:

$$D^* = \frac{\sqrt{A\,x\,\Delta f}}{NEP} = R\,x\,\frac{\sqrt{A\,x\,\Delta f}}{i_{noise}} \qquad (3)$$

Burada A diyot alanını, q elektron yükünü, R responsiviteyi, i_n gürültü akımını ve Δf elektriksel bant genişliğini ifade etmektedir. Spesifik dedektivitenin uygulanan gerilime bağlı değişimi Şekil 3'te gösterilmiştir. D* değerinin negatif gerilim bölgesinde gerilime bağlı olarak belirgin bir değişim gösterdiği ve yaklaşık −1,3 V civarında $1{,}0 \times 10^{11}$ Jones ile maksimum değerine ulaştığı görülmektedir. Maksimum değerin ardından, gerilimin 0 V'a yaklaşmasıyla D* değerinde belirgin bir düşüş meydana gelmekte ve değer sıfıra yaklaşmaktadır. Bu sonuçlar, incelenen gerilim aralığında en yüksek spesifik dedektivitenin yaklaşık −1,3 V civarında elde edildiğini göstermektedir.

Şekil 3. Bi katkılı GQD hibrit yapının uygulanan gerilime bağlı spesifik dedektivite (D*) değişimi.

Başlangıç ve 24 ay sonraki fotodedektör karakterizasyonunda −4 V'ta elde edilen performans değerleri Tablo 1'de karşılaştırmalı olarak sunulmuştur. Başlangıç performans değerleri daha önce yayımlanan çalışmamızdan (Berktaş vd., 2026) alınmış olup, söz konusu çalışmaya ait grafikler bu çalışmada yeniden kullanılmamıştır. Bunun yerine, başlangıç ve 24 ay sonraki karakterizasyon sonuçları sayısal

olarak karşılaştırılmıştır. Başlangıç karakterizasyonunda, 96 mW/cm² ışık yoğunluğu altında R, S, EQE ve D* değerleri sırasıyla 0,12 A/W, 9×10^2, %27 ve $5,6 \times 10^{10}$ Jones olarak raporlanmıştır (Berktaş vd., 2026). Yirmi dört ay sonra, 100 mW/cm² ışık yoğunluğu altında elde edilen R, S, EQE ve D* değerleri ise sırasıyla 0,33 A/W, $3,3 \times 10^2$, %74 ve $5,8 \times 10^{10}$ Jones olarak belirlenmiştir.

Tablo 1. Bi katkılı GQD hibrit yapının başlangıç ve 24 ay sonraki fotodedektör performansının karşılaştırılması.

Fotodedektör performans metriği	**Başlangıç ölçümü (96 mW/cm²)**	**24 ay sonraki ölçüm (100 mW/cm²)**
Hassasiyet, S	9×10^2	$3,3 \times 10^2$
Responsivite, R (A/W)	0,12	0,33
Spesifik dedektivite, D* (Jones)	$5,6 \times 10^{10}$	$5,8 \times 10^{10}$
Dış kuantum verimi, EQE (%)	27	74

Spesifik dedektivite değerindeki sınırlı değişim, cihazın 24 aylık bekletme sonrasında algılama kabiliyetini büyük ölçüde koruduğunu göstermektedir. Responsivite ve EQE değerlerindeki artış ise cihazın 24 ay sonra da ölçüm koşulları altında güçlü bir fotocevap sergilemeye devam ettiğini ortaya koymaktadır.

Genel olarak elde edilen sonuçlar, Bi katkılı GQD tabanlı heteroeklemin 24 aylık bekletme sonrasında fotodedektör işlevselliğini büyük ölçüde koruduğunu göstermektedir. Özellikle spesifik dedektivitenin başlangıç değerine yakın kalması, cihazın düşük seviyeli optik sinyalleri algılama kabiliyetinin korunduğuna işaret etmektedir. Bununla birlikte, hassasiyet değerinde gözlenen azalma, fotodedeksiyon parametrelerinin tamamının aynı eğilimi göstermediğini ortaya koymaktadır. Başlangıç ve 24 ay sonraki ölçümlerin farklı ölçüm sistemleri kullanılarak gerçekleştirilmiş olması nedeniyle, gözlenen değişimlerin yalnızca bekletme süresinden kaynaklandığı şeklinde doğrudan bir değerlendirme yapılmamalıdır.

SONUÇ

Bu çalışmada, hidrotermal yöntemle sentezlenen Bi katkılı GQD'ler kullanılarak p-tipi Si tabanlı bir heteroeklem fotodedektör oluşturulmuş ve cihazın fotodedeksiyon performansı 24 aylık bekletme sonrasında yeniden incelenmiştir. Başlangıç ve 24 ay sonraki karakterizasyonlarda farklı ölçüm sistemlerinin ve birbirine yakın ancak aynı olmayan ışık yoğunluklarının kullanılması nedeniyle, elde edilen sonuçlar tamamen aynı deneysel koşulları temsil etmemektedir. Bu nedenle, fotodedeksiyon parametrelerinde gözlenen değişimlerin yalnızca 24 aylık bekletme süresinden kaynaklandığı şeklinde kesin bir nedensellik kurulması uygun değildir.

Bununla birlikte, 24 ay sonraki ölçümlerde cihazın belirgin bir fotocevap sergilemeye devam ettiği görülmüştür. Responsivite ve EQE değerleri başlangıç ölçümlerine göre daha yüksek değerler gösterirken, spesifik dedektivite başlangıç değerine yakın kalmış, hassasiyet ise azalmıştır. Bu sonuçlar, farklı performans parametrelerinde farklı değişimler gözlenmesine rağmen, Bi katkılı GQD tabanlı heteroeklemin 24 aylık bekletme sonrasında fotodedektör işlevselliğini büyük ölçüde koruduğunu göstermektedir. Elde edilen bulgular, Bi katkılı GQD tabanlı heteroeklemlerin uzun dönemli optoelektronik uygulamalardaki potansiyelinin değerlendirilmesi açısından önemli bir gösterge sunmaktadır.

ABSTRACT

In proton exchange membrane fuel cells (PEMFCs), the high cost of platinum-based catalysts and the slow kinetics of the oxygen reduction reaction (ORR) occurring at the cathode necessitate the development of electrocatalysts that are more active and durable, and possess higher Pt utilization efficiency. In this context, this review evaluates the effects of nitrogen (N), sulfur (S), and phosphorus (P) doping on carbon-supported Pt and Pt-based bimetallic electrocatalysts, particularly regarding metal–support interactions, catalyst layer structure, ORR performance, and durability. Recent studies demonstrate that the effects of heteroatom doping cannot be explained solely by the total heteroatom content; the structural configuration of the heteroatom, the synthesis method, the structure of the carbon support, and the properties of the metallic phase are also determining factors. While N-doping can alter surface chemistry, metal coordination, and support–ionomer interactions, S-modification can regulate ionomer distribution, proton accessibility, oxygen transport, and interfacial charge transfer. P-doping, on the other hand, is particularly associated with strengthening the Pt–support interaction, limiting nanoparticle migration, and enhancing long-term electrochemical stability. However, improvements in ORR activity and durability cannot be attributed solely to heteroatom doping, as alloy composition, particle size, and support structure also simultaneously influence catalytic performance. Therefore, future catalyst designs must consider the heteroatom type and configuration in conjunction with metal–support interactions, low Pt loading, transport processes within the catalyst layer, and long-term operational stability in PEMFCs.

Keywords: Electrocatalyst, heteroatom, carbon support materials

ÖZET

Proton değişim membranlı yakıt hücrelerinde (PEMFC'ler), platin bazlı katalizörlerin yüksek maliyeti ve katotta gerçekleşen oksijen indirgenme reaksiyonunun (ORR) yavaş kinetiği; daha aktif, daha dayanıklı ve daha yüksek Pt kullanım verimliliğine sahip elektrokatalizörlerin geliştirilmesini zorunlu kılmaktadır. Bu bağlamda söz konusu derleme; özellikle metal-destek etkileşimleri, katalizör katmanı yapısı, ORR performansı ve dayanıklılık açısından, karbon destekli Pt ve Pt tabanlı bimetalik elektrokatalizörler üzerindeki azot (N), kükürt (S) ve fosfor (P) katkılamasının etkilerini değerlendirmektedir. Yakın tarihli çalışmalar, heteroatom katkılamasının etkilerinin yalnızca toplam heteroatom içeriğiyle açıklanamayacağını; heteroatomun yapısal konfigürasyonu, sentez yöntemi, karbon desteğin yapısı ve metalik fazın özelliklerinin de belirleyici faktörler olduğunu göstermektedir. N-katkılama yüzey kimyasını, metal koordinasyonunu ve destek-iyonomer etkileşimlerini değiştirebilirken; S-modifikasyonu iyonomer dağılımını, proton erişilebilirliğini, oksijen taşınımını ve arayüzey yük transferini düzenleyebilir. Öte yandan P-katkılama; özellikle Pt-destek etkileşiminin güçlendirilmesi, nanoparçacık göçünün sınırlandırılması ve uzun vadeli elektrokimyasal kararlılığın artırılması ile ilişkilidir. Bununla birlikte, ORR aktivitesi ve dayanıklılığındaki iyileşmeler yalnızca heteroatom katkılamasına atfedilemez; zira alaşım bileşimi, parçacık boyutu ve destek yapısı da katalitik performansı eş zamanlı olarak etkilemektedir. Bu nedenle, gelecekteki katalizör tasarımları; metal-destek etkileşimleri, düşük Pt yüklemesi, katalizör katmanı içindeki taşınım süreçleri ve PEMFC'lerdeki uzun vadeli operasyonel kararlılıkla birlikte heteroatom türü ve konfigürasyonunu da dikkate almalıdır.

Anahtar kelimeler: Elektrokatalizör, heteroatom, karbon destek malzemeleri

1. INTRODUCTION

Proton exchange membrane fuel cells (PEMFCs) are electrochemical systems that convert chemical energy directly into electrical energy and hold significant potential for various application areas. The efficient and stable operation of these systems depends on the kinetics of the electrochemical reactions occurring at the electrodes and the properties of the electrode materials used. In particular, the relatively slow kinetics of the oxygen reduction reaction (ORR) at the cathode is one of the main factors limiting PEMFC performance **(**Luo & Koper, 2022).

Support materials used in the catalyst layer of PEM fuel cells play a crucial role in establishing electron transport pathways within the electrode. In carbon-supported catalysts, the carbon network formed by the support materials creates the electron transport channel within the membrane electrode assembly (MEA), while catalytic particles are dispersed across the carbon surface (Figure 1). Carbon supports have to provide high surface area, high electrical conductivity and good metal-support interactions for high electrocatalyst activity.

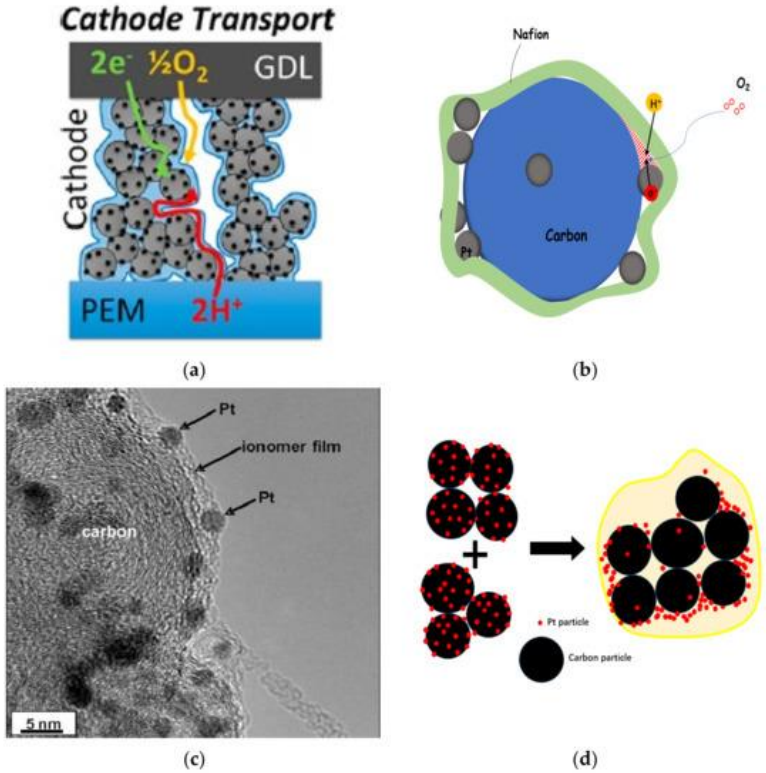

Figure 1. (a) Schematic representation of the structure and electron and proton transport on the cathode side of the MEA. (b) Schematic representation of the three-phase boundary region at the PEMFC cathode. (c) Microscopic image of the Pt particle–ionomer–carbon support microstructure. (d) Schematic representation of the secondary distribution of Pt nanoparticles on the support during the preparation of the catalyst layer (Xie et al., 2021).

The structure of the catalyst layer consists of particles, aggregates, and pores of varying sizes. Carbon support particles typically form aggregates through the binding action of the ionomer, with catalytic particles dispersed on the surfaces of these aggregates. Adequate transport pathways must exist within the catalyst layer to facilitate the transport of electrons, protons, reactant gases, and product water. Consequently, the carbon support structure, ionomer distribution, and the resulting porous structure constitute the fundamental components of the catalyst layer's structural characteristics (Xie et al., 2021). Platinum (Pt)-based materials are among the primary electrocatalysts in PEMFC cathodes due to their high ORR activity. However, the cost of Pt, its limited availability, and potential performance losses under prolonged operating conditions necessitate the development of more efficient and robust catalysts. Accordingly, reducing the amount of Pt, alloying with a second metal or creating intermetallic structures, and controlling the electronic and structural properties of the catalyst are considered among the main material design strategies (Kim et al., 2024; Song et al., 2022; Xue et al., 2024).

Combining Pt with transition metals such as Ni, Co, Cu, and Fe to reduce Pt usage while simultaneously increasing ORR activity is an important catalyst design approach. The electrocatalytic performance of these PtM (M= Ni, Co, Cu, Fe, etc.) alloy nanostructures is influenced by interrelated factors such as the arrangement of the d-band center, strain effect, particle size, and surface structure. These electronic and structural changes can alter ORR kinetics by regulating the interaction of Pt active sites with intermediate species. However, despite high platinum utilization and significant advances in bulk activity, achieving high activity along with long-term durability remains a significant challenge for PEMFC electrocatalysts (Kim et al., 2024).

New active sites in electrocatalysts can also be achieved via heteroatom doping which is an important approach for modifying surface properties, electronic structure, metal-support interaction, active center formation, and catalyst stability in PEM fuel cell electrocatalysts (Figure 2). This paper discusses the effects of heteroatom doping on the electronic and structural properties of Pt and Pt-based bimetallic electrocatalysts. Furthermore, based on current literature studies, the relationships between catalyst structure, heteroatom type, ORR performance, and electrochemical stability are evaluated.

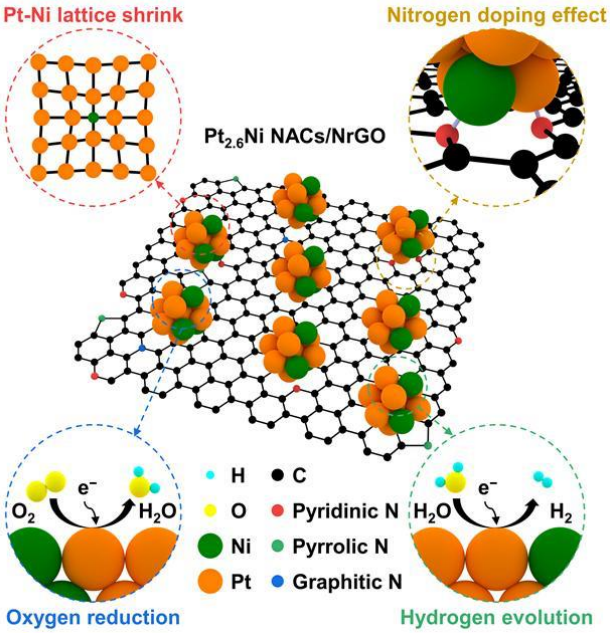

Figure 2. Schematic representation of a Pt–Ni catalyst supported on nitrogen-doped carbon

2. EFFECTS OF HETEROATOM DOPING ON THE PROPERTIES OF ELECTROCATALYTIC MATERIALS

The addition of heteroatoms to carbon structures can alter the electronic and surface properties of the carbon support, contributing to the regulation of the interaction between metal nanoparticles and the support. Heteroatom-doped carbon supports can have positive effects on ORR activity and electrochemical resistance by promoting more efficient attachment of metal species and the establishment of a stable structure for alloy nanoparticles (Zhang et al., 2023).

2.1. Nitrogen Addition

Nitrogen (N) doping is one of the approaches used to modify support-ionomer interactions within the catalyst layer and the surface properties of the carbon support in PEMFC cathode catalysts. Nitrogen-doped carbon supports can contain different types of nitrogen (Figure 3), and the resulting surface properties can vary depending on the nitrogen source used and the synthesis method applied. Therefore, evaluating the effect of N-doped carbon supports on PEMFC performance solely based on the total nitrogen content is insufficient.

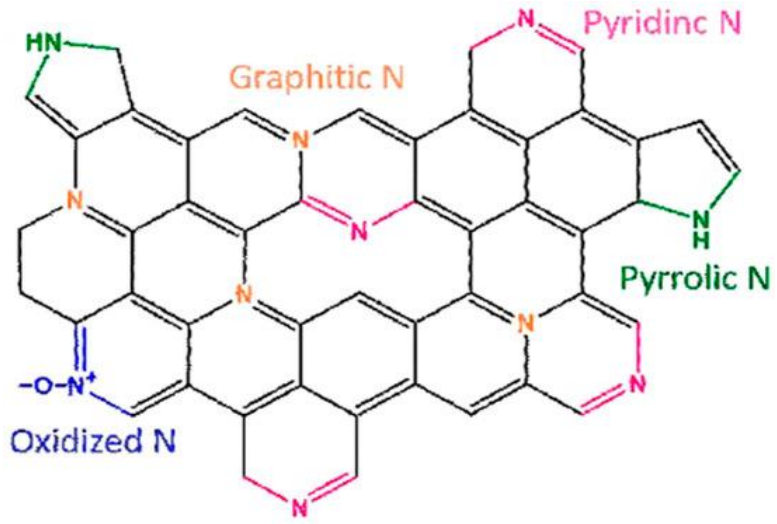

Figure 3. The four nitrogen doping configurations usually observed on carbon catalysts (Zhou et al., 2018)

Ott et al. demonstrated that in N-doped high surface area carbon supports prepared using different nitrogen precursors, the nitrogen source and modification method significantly affect the physicochemical properties of the support and the resulting catalyst layer behavior. In this study, the interaction of N-doped carbons with the ionomer was evaluated using electrochemical surface area, proton resistance, cell performance under humidity conditions, and limiting current measurements. XPS results revealed an interaction between the basic N groups on the carbon surface and the acidic side chains of the ionomer. Furthermore, it was determined that the presence of only N-containing surface groups did not guarantee a more homogeneous or suitable ionomer distribution; the resulting effect depended on the N precursor used and the changes in the physicochemical properties of the carbon support caused by the synthesis pathway (Ott et al., 2022). It has been reported that these changes can affect PEMFC performance by influencing proton transport and other transport resistances in the catalyst layer.

The effect of nitrogen doping on the performance and stability of Pt-based catalysts under PEMFC operating conditions was also investigated by Hornberger et al. It was reported that the ORR activity and stability of Pt/N-C catalysts prepared by depositing highly homogeneous Pt nanoparticles onto N-doped carbons were comparable to those of current PEMFC catalysts. The study, which combined electrochemical measurements in a liquid electrolyte environment with single-cell membrane electrode assemblies (MEAs), revealed that the effect of N doping cannot be explained solely by conventional electrochemical tests. It has been determined that N-doped carbon supports can improve cell performance, especially under conditions of 0.6–0.9 V, which is the normal operating range of PEMFCs (Hornberger et al., 2022). However, the effect of N addition on the strength of the carbon support was not found to be in the same direction. Hornberger et al. showed that the addition of nitrogen heteroatoms to the carbon structure was not sufficient to prevent carbon corrosion in high-potential cycles between 1.0–1.5 V. Therefore, although N addition can improve catalyst performance under normal PEMFC operating conditions (0.6–0.9 V), it does not provide a direct protective effect against the degradation of the carbon support at high potentials (Hornberger et al., 2022).

In the literature, two different nitrogen doping strategies were followed. In the first case, Pt electrocatalysts were synthesized over nitrogen doped carbon materials and in the second case synthesized Pt electrocatalysts were nitrogen doped. It was observed that nitrogen doping of electrocatalysts showed better PEMFC performance when compared to the nitrogen doping of carbon supports (Çelik & Bayrakçeken, 2025).

It is seen that the effect of N doping in PEMFCs cannot be attributed solely to nitrogen content or the amount of a specific type of N. The N precursor used and the support-ionomer interaction that occurs with the synthesis method, surface properties, and proton and mass transport processes in the catalyst layer are interconnected factors that determine the cell performance of N-doped carbon supports (Ott et al., 2022). Furthermore, while N additives can improve cell performance under normal PEMFC

operating conditions, they are not sufficient on their own to prevent carbon corrosion occurring at high operating potentials (Hornberger et al., 2022).

2.2. Sulfur Addition

Sulfur (S)-modified carbon structures can be used in PEMFC cathodes not only as a support material that alters the environment of the catalytic phase, but also as an approach that can regulate metal-support and ionomer-support interactions within the catalyst layer. Zhang et al. demonstrated that modification of the carbon support with thiophenic-S groups could alter the distribution of the PFSA ionomer on the catalyst layer. The interaction between the thiophenic-S sites and the sulfonic acid-containing side chains of the ionomer contributed to a more favorable distribution of the ionomer on the Pt_3Co/S–KB catalyst (Figure 4). This improved accessibility of the catalytic sites to proton transport pathways while reducing resistance to oxygen transport (Zhang et al., 2025). This study contributed to the more effective utilization of active Pt sites at lower Pt loadings and the improvement of three-phase reaction sites in the catalyst layer. The study reported that MEA containing Pt_3Co/S–KB achieved a nominal power density of 1.06 W cm^{-2} at 0.67 V under H_2/air conditions (Zhang et al., 2025). Based on the results, it is predicted that the effect of S modification in PEMFCs should be evaluated not only in terms of ORR kinetics but also in conjunction with electrode-level processes such as proton accessibility, oxygen transport, and catalyst-ionomer interface.

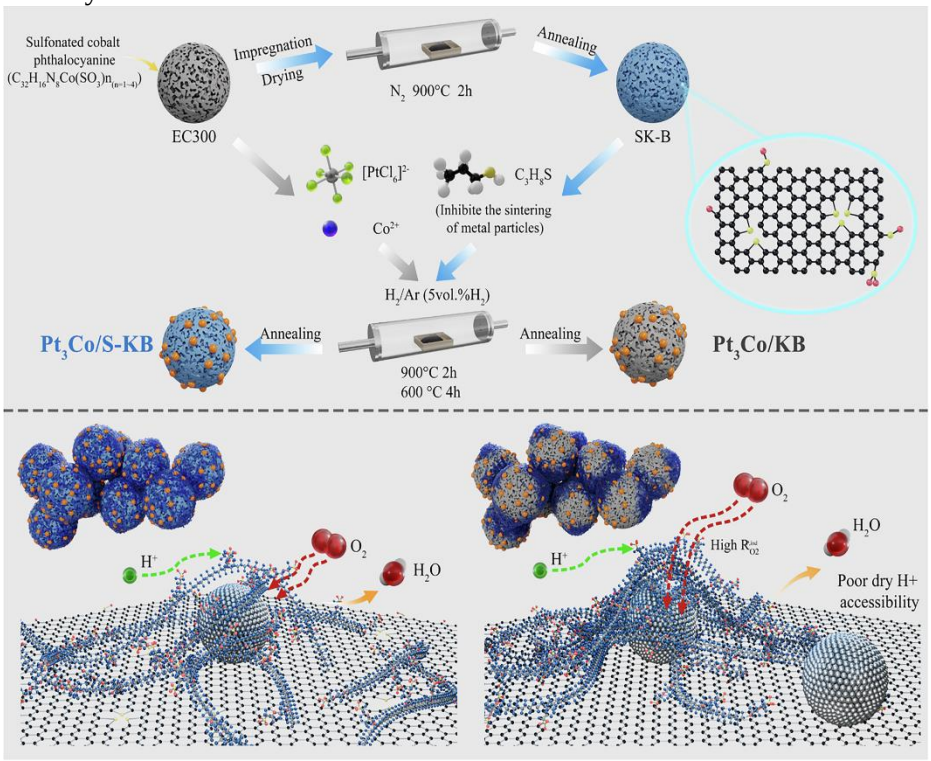

Figure 4. Top Image: Synthesis process of Pt-Co alloy catalyst supported by small molecule-assisted impregnation onto conventional carbon support EC300 (indicated by the gray arrow) and modified S-KB (indicated by the blue arrow). The main difference is that S-KB is modified with thiophene S. Bottom Images: Pt_3Co/S-KB (bottom left image) and Pt_3Co/KB (bottom right image) (Zhang et al., 2025).

Another important effect of sulfur doping in PEMFC electrocatalysts is related to the regulation of interfacial interactions between metal nanoparticles and carbon support. Niu et al. developed a three-dimensional ORR catalyst with low Pt content by modifying a Pt–Co nanoalloy with an S-doped Co–N–C structure. In this study, it was stated that the co-doping of N and S can enhance the metal-support interaction between Pt/Pt–Co and S-doped Co–N–C by regulating charge transfer at the interface (Niu et al., 2024). This integrated structure demonstrated electrochemical stability and improved ORR activity when compared to commercial Pt/C. Therefore, this study reveals that sulfur (S) doping can contribute to the regulation of the metal-support interface in Pt–Co-based systems, and this can play a role in improving catalytic activity and stability (Niu et al., 2024).

When the literature studies are evaluated together, explaining the sulfur doping in PEMFC electrocatalysts through a single mechanism is not considered sufficient. Sulfur-containing carbon structures contribute to the regulation of ionomer distribution in the catalyst layer and can also affect interfacial interactions and charge transfer between Pt-based structures and the support. Therefore, the contribution of sulfur modification to PEMFC performance should be evaluated within the framework of interconnected processes such as metal-support interaction, ORR activity, proton accessibility, Pt utilization efficiency, and oxygen transport (Niu et al., 2024; Zhang et al., 2025).

2.3. Phosphorus Addition

Phosphorus (P) doping is used in PEMFC electrocatalysts to both improve the stability of the Pt-based active phase and enhance the interaction of the carbon support with Pt nanoparticles. Shen et al. demonstrated that phosphorus in a P-doped PtCo/C catalyst contributes to the improvement of ORR performance, and especially long-term stability, by modifying the electronic and structural properties of PtCo nanoparticles. A bulk activity of 0.72 Å $mgPt^{-1}$ was obtained at 0.9 V in the P5–PtCo/C catalyst, which is 4.5 times higher than that of commercial Pt/C. Furthermore, the loss in bulk activity after 30,000 potential cycles was determined to be only 9.4% (Shen et al., 2023). These results demonstrate that P doping can contribute to maintaining the stability of PtCo nanoparticles under electrochemical conditions.

Phosphorus can improve the ability of carbon supports to retain Pt nanoparticles in PEMFC catalysts. Kim et al. reported that doping a carbon support with a high crystalline structure and inherent hydrophobic properties with phosphorus resulted in more effective stabilization of Pt nanoparticles on the support surface (Figure 5). Phosphorus-containing regions strengthened the Pt-support interaction, limiting the movement of Pt nanoparticles and associated structural changes, thereby improving the long-term electrochemical stability of the catalyst. The Pt/HCCp (HCCp: phosphorus-doped high crystalline carbon support) catalyst showed only a 2 mV half-wave potential shift and a 1.9% electrochemical surface area loss after 20,000 cycles of endurance testing. In single-cell tests, it was reported that 92.4% of the initial power density was retained (Kim et al., 2026).

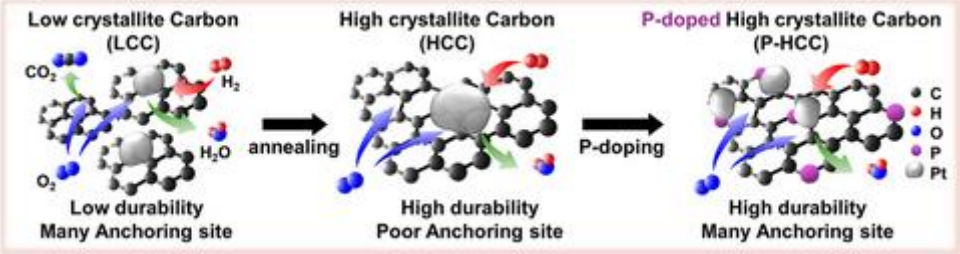

Figure 5. Relationship between durability, carbon defects, and Pt binding points in various carbon supports (Kim et al., 2026).

When these literature studies are evaluated together, it is seen that phosphorus doping in PEMFC electrocatalysts is not limited to simply increasing ORR activity. The fact that P improves the stability of the PtCo-based active phase and contributes to the stronger fixation of Pt nanoparticles on the carbon support can help maintain the structural integrity of the catalyst during long-term use. Therefore, phosphorus doping can be considered as an approach to simultaneously improve electrochemical stability and metal-support interaction in Pt-based PEMFC catalysts (Kim et al., 2026; Shen et al., 2023).

2.4. Multiple Heteroatom Doping

The incorporation of multiple heteroatoms into a carbon support is one of the approaches used to regulate metal-support interaction and support structure in Pt-based electrocatalysts. The ORR performance observed in such systems is not solely due to heteroatom doping; metal alloying, structural properties of the carbon support, and metal-support interaction also have a combined effect on the catalytic behavior. Zhang et al. prepared PtCu alloy nanoparticles on N and P-doped carbon supports via microbial adsorption followed by carbonization-reduction. Among the catalysts obtained, PtCu/NPC-700 °C showed the highest ORR performance and reached a mass activity of 0.895 A $mgPt^{-1}$ at 0.9 V. This value has been reported to be approximately 8.29 times that of the commercial Pt/C catalyst (Zhang et al., 2023). The high ORR performance obtained in the study was evaluated based on the catalytic structure formed by the properties of the carbon support containing N and P and the PtCu alloy structure.

Therefore, instead of attributing the performance increase in the PtCu/NPC system solely to the N and P additions, the combined effect of the co-added carbon support and the PtCu alloy is considered.

The effect of multi-doped carbon supports on Pt-based intermetallic catalysts was investigated by Lu et al. on a Pt_2CuFe system. In this study, a multi-doped carbon support containing Pt, Cu, Fe, Cr, S, and N formed strong metal-support interactions with Pt_2CuFe clusters, limiting particle growth during high-temperature heat treatment. Highly ordered Pt_2CuFe intermetallic nanoparticles with a size of approximately 2.2 nm were obtained even after annealing at 800 °C. The prepared Pt_2CuFe/MHC (MHC: multi-heteroatom doped carbon) catalyst showed a mass activity of 2.07 Å $mgPt^{-1}$ ORR and retained 64% of its initial mass activity after 40,000 voltage cycles. In MEA tests, a peak power density of 1.29 W cm^{-2} was reached under H_2/air conditions, and a voltage drop of only 25 mV was determined at a current density of 0.8 A cm^{-2} (Lu et al., 2026).

It can be seen that carbon supports containing multiple heteroatoms can improve the stability of metal nanoparticles on the support and the metal-support interaction in Pt-based catalysts. However, since the effects of heteroatom addition and alloy or intermetallic structure occur together in systems such as Pt_2CuFe/MHC and PtCu/NPC, it is not appropriate to consider the observed increase in ORR activity and strength as solely the effect of a specific heteroatom (Lu et al., 2026; Zhang et al., 2023).

3. HETEROATOM-DOPED CARBON SUPPORTS and Pt-BASED BIMETALLIC CATALYSTS

The use of heteroatom-doped carbon supports in combination with Pt-based bimetallic catalysts represents a significant approach to regulating the interaction between the active metal phase and the carbon support. In these systems, catalytic performance depends not only on the alloy structure between Pt and the second metal, but also on the interface formed by the metal nanoparticles with the carbon support, which can play a decisive role in activity and stability.

Huang et al. designed a catalyst that integrates a Co–N–C matrix containing N with a Pt-based metal phase and reported that the resulting structure exhibits significantly higher ORR bulk activity compared to commercial Pt/C. Furthermore, the high activity retention of the catalyst after long-term potential cycles suggests that modifying the Pt-based active phase with an N-containing carbon matrix may be effective in improving both catalytic activity and stability (Huang et al., 2022).

The effect of the metal-support interface on the electronic structure of Pt was investigated in detail by Xue et al. on PtFe nanocrystals and N-doped carbon supports containing atomically dispersed Fe centers. The PtFe@Fe_{SAs}–N–C catalyst achieved a mass activity of 0.75 A $mgPt^{-1}$ at 0.9 V and a peak power density of 1.24 W cm^{-2} in PEMFC tests. Furthermore, it retained 97% of its initial mass activity after 30,000 cycles and showed no significant current loss for 220 hours at 0.6 V. The study concluded that the interaction between atomic Fe centers on the support and the PtFe alloy regulates the occupancy state of the Pt d-orbital, and this modifies its interaction with ORR intermediates (Xue et al., 2024).

In a similar study, Pt–Ni was investigated together. Yan et al. developed a system in which two different active structures are integrated within the same catalyst by modifying atomically dispersed Ni–N_4 regions with Pt_3Ni nanolattices that have a Pt-rich surface. The study reported that the interaction between Ni–N_4 regions and the Pt_3Ni structure contributed to the improvement of ORR activity and stability (Yan et al., 2023). This result demonstrates that the combination of heteroatom-coordinated metal regions with Pt-based alloy nanoparticles can be effective in regulating catalytic properties.

In determining the stability of metal nanoparticles on a support, not only heteroatom contribution but also binding sites in the carbon structure can be important. Cui et al. fixed approximately 2.6 nm Pt_1Ni_1@Pt/C core-shell nanoparticles on a support by exploiting structural irregularities on the carbon. The strong Pt–C interaction that occurred resulted in the catalyst showing only a 1.6% loss in activity even after 70,000 potential cycles, and prevented the agglomeration of nanoparticles (Cui et al., 2024). This study directly demonstrates that metal-carbon interaction can play a significant role in maintaining nanoparticle size and distribution.

It can be summarized that modifying Pt-based bimetallic or intermetallic structures with heteroatom-doped carbon supports can affect ORR performance in different ways. Heteroatom-containing coordination regions contribute to the improvement and regulation of the electronic properties of the metal-support interface (Huang et al., 2022; Xue et al., 2024; Yan et al., 2023), while strong metal-carbon interactions can also contribute to maintaining structural stability by limiting the agglomeration and migration of nanoparticles (Cui et al., 2024).

Therefore, in PEMFC catalysts where heteroatom doping and bimetallic alloying are used together, strength and activity must be evaluated considering both metal-support interaction and the electronic structure of the metal phase.

The literature studies given above are summarized in Table 1 in order to give a brief information about the effects of heteroatom doping on PEMFC performance.

Catalyst	Heteroatom	Support	Synthesis Approach	PEMFC Performance	Source
Pt/N-C	N	N-functional carbon black	Surface N-modification with different N-precursors; Pt loading and MEA preparation	Some N-modified carbon supports have improved PEMFC performance; this improvement has been shown to be due more to increased oxygen mass transport resulting from the altered pore structure during synthesis than to the N addition itself.	Ott et al., 2022
Pt/N-C	N	Pyridinic-N content adjusted carbon	Controlled N-doping and Pt nanoparticle loading	N addition improved performance under PEMFC operating conditions; this improvement was attributed to improved ionomer distribution due to high pyridinic-N content. However, carbon corrosion resistance was negatively affected.	Hornberger et al., 2022
PtCo@CoNC/NTG (NTG: nitrogen-doped tubular graphene)	N	Co–N–C containing nanocarbon network	Synthesis of multiscale Pt–Co/Co–N–C nanocarbon electrocatalysts.	PtCo@CoNC/NTG achieved a mass activity of 1.52 A $mgPt^{-1}$, 11.7 times that of commercial Pt/C; It showed only a 1.3% loss after 30,000 cycles and provided a power density of 980 mW cm^{-2} at 0.6 V.	Huang et al., 2022
PtCu/NPC-700	N, P	N,P co-doped porous carbon	Pyrolysis of microbial precursor and PtCu loading	PtCu/NPC reached a mass activity of 0.895 A $mgPt^{-1}$ at 700 °C and 0.9 V, which is 8.29 times that of Pt/C; It showed low ECSA and activity losses after 10,000 cycles and exhibited higher activity and resistance than Pt/C in single-cell tests.	Zhang et al., 2023
P5-PtCo/C(5: 5 mg phytic acid)	P	P-doped carbon / PtCo	One-step hydrothermal synthesis using phytic acid.	P5-PtCo/C reached approximately 4.5 times the mass activity of Pt/C with 0.72 A $mgPt^{-1}$ at 0.9 V; Activity loss after 30,000 and 70,000 cycles was 9.4% and 37.7%, respectively. P addition enhanced the PtCo–carbon interaction and catalyst stability.	Shen et al., 2023
Pt–Co/S–Co–N–C	S, N	S-doped Co–N–C	Integration of Pt–Co nanoalloy with S-doped Co–N–C in a 3D hybrid structure	The 3D LPCNSC catalyst, obtained by combining a Pt–Co nanoalloy with an S-doped Co–N–C structure in a three-dimensional architecture, demonstrated higher ORR activity and stability compared to commercial 20% Pt/C despite its lower Pt content	Niu et al., 2024

				of 13.65%. Under H_2/O_2 conditions, the maximum power density reached 983.8 mW cm^{-2}.	
PtFe@Fe_{SAs}–N–C (SAs: single atoms)	N	One-atom Fe–N–C	Formation of ultra-thin PtFe alloy nanocrystals on N-doped carbon (Fe_{SAs}–N–C) containing atomic Fe centers	PtFe@FeSAs-N-C achieved a mass activity of 0.75 A $mgPt^{-1}$ and a peak power density of 1.24 W cm^{-2} at 0.9 V; It maintained 97% of its activity after 30,000 cycles and showed no significant performance loss in a 220-hour PEMFC test.	Xue et al., 2024
Pt_3Co/S-KB (KB: Ketjenblack)	S	Ketjenblack with thiophenic-S modification	Modification of ketonblack carbon support with thiophenic-S followed by loading of Pt_3Co alloy nanoparticles	Ketjenblack (S-KB), modified with thiophene-S, improved proton and O_2 transport by homogenizing the ionomer distribution; The Pt_3Co/S-KB catalyst demonstrated high PEMFC performance at low Pt loading and exceeded the U.S. Department of Energy (DOE) nominal power and Pt utilization targets.	Zhang et al., 2025
Pt/HCCP (P-doped high crystalline carbon supported Pt)	P	Phosphorus-doped high crystalline carbon (HCCP)	Doping of highly crystalline carbon with P via spin-on doping (SOD) method followed by loading of Pt nanoparticles.	Pt/HCC_P (P-doped high crystalline carbon supported Pt) achieved a maximum power density of 0.98 W cm^{-2}; After 20,000 ADT cycles, the power density decreased by only 7.6%, while the loss in Pt/LCC was 58.7%. P addition significantly increased the strength of PEMFC by improving the dispersion and anchoring of Pt nanoparticles.	Kim et al., 2026
Pt_2CuFe/MHC (MHC: carbon with multiple heteroatoms)	N, S	Carbon with multiple heteroatoms (MHC)	Formation of Pt_2CuFe intermetallic structure on multi-heteroatom doped carbon support by immersion-pyrolysis-reduction	Pt_2CuFe/MHC reached a mass activity of 2.07 A $mgPt^{-1}$ at 0.9 V; In MEA tests, it showed peak power densities of 1.29 and 3.14 W cm^{-2} under H_2-air and H_2-O_2 conditions, respectively, and retained 85.3% of its activity after 30,000 cycles.	Lu et al., 2026

4. CONCLUSIONS AND RECOMMENDATIONS

Heteroatom-doped carbon-supported structures offer a significant material design approach for improving the strength and activity of Pt-based PEMFC electrocatalysts. Literature studies indicate that the effect of heteroatoms such as N, S, and P cannot be explained solely by the total doping amount. The synthesis methods and heteroatom types used can alter the surface properties of the carbon support, the ionomer distribution in the catalyst layer, and the metal-support interaction. These changes can affect the stability of the catalyst and its ORR performance (Hornberger et al., 2022; Kim et al., 2026; Ott et al., 2022; Shen et al., 2023; Zhang et al., 2025). Therefore, the effect of heteroatom doping needs to be evaluated together with the electrochemical and structural properties of the catalyst.

The combined use of bimetallic systems such as PtFe, PtCo, PtNi, and PtCu with heteroatom-doped carbon supports yields remarkable results in terms of regulating the metal-support interface (Huang et al., 2022; Niu et al., 2024; Xue et al., 2024; Yan et al., 2023; Zhang et al., 2023). Furthermore, when heteroatom addition and alloying or intermetallic structure change together within the same system,

attributing the observed performance improvement solely to heteroatom addition cannot be considered appropriate.

Future studies will require comparative experimental designs that can evaluate the effects of heteroatom amount and type as independently as possible from metal particle size, alloy composition, and the structural properties of the carbon support. Furthermore, it should be considered that the analysis and characterization results may not fully reflect the catalyst structure of PEMFCs under actual operating conditions. For these reasons, investigating the interactions between catalyst components under real operating conditions is important for a more accurate understanding of the mechanisms that determine performance.

Catalyst development studies should not focus solely on the high initial ORR activity obtained under rotating disk electrode (RDE) conditions. The effect of heteroatom doping on PEMFC performance should be determined by evaluating long-term durability, low Pt loading, proton and oxygen transport, and MEA performance as a whole. In this context, ionomer distribution in the catalyst layer and accessibility of active sites are also important factors determining cell performance. The primary goal in the future development of heteroatom-doped Pt-based catalysts should be to create systems that simultaneously provide high ORR activity, low Pt loading, high stability, and suitable catalyst layer properties.

ÖZET

Polianilin (PANI), oda sıcaklığında amonyum persülfatın oksidan olarak kullanıldığı 1 M hidroklorik asit ortamında anilinin kimyasal oksidatif polimerizasyonu yoluyla sentezlendi; bu işlem sonucunda polimerin iletken emeraldin tuzu formu koyu renkli bir toz halinde elde edildi. HCl ile doplanmış PANI daha sonra sulu çözeltiden katyonik boya metilen mavisi (MB^+) için bir adsorban olarak değerlendirildi. Sabit MB^+ konsantrasyonu (100 ppm) koşulunda, başlangıç çözeltisinin pH'ının etkisi 2-10 aralığında incelendi ve en yüksek adsorpsiyon pH 3'te elde edildi. Ardından, bu pH değerinde, 0,1 g/10 mL adsorban dozu kullanılarak 10-1000 ppm başlangıç konsantrasyon aralığında konsantrasyona bağlı adsorpsiyon incelendi. Deneysel izotermler Langmuir, Freundlich ve Temkin modellerine uygulandı. Üç model için de uyum anlamlı bulundu. Langmuir modeli en iyi açıklamayı sağladı (R^2 = 0,991) ve 1429 L mol^{-1}' lik bir Langmuir sabiti ile 0,07 mol kg^{-1} (≈22 mg g^{-1}) tek tabaka kapasitesi tanımladı. Freundlich heterojenlik parametresi (β = 0,49) ve Temkin enerji faktörü (A_T = 30,82 × 10^3 L mol^{-1}) de hesaplandı. Langmuir ve Temkin sabitlerinden hesaplanan Gibbs serbest enerji değişimleri sırasıyla -17,99 ve -25,61 kJ mol^{-1} olarak bulundu; bu da HCl ile doplanmış PANI üzerinde MB^+ adsorpsiyonunun kendiliğinden gerçekleştiğini gösterdi. Langmuir kinetik yaklaşımıyla yapılan değerlendirme sonucunda $\Theta_{e,theor} - k_1/k_2 < 0$ değeri elde edildi; bu sonuç sürecin birinci dereceden hız davranışını izlediğini gösterdi. Sonuçlar, herhangi bir destek veya kompozit modifikasyonu içermeyen HCl katkılı PANI'nin, katyonik boyaların giderilmesinde etkili bir adsorban olduğunu ortaya koymaktadır.
Anahtar kelimeler: Polianilin, HCl doplama, oksidatif polimerizasyon, metilen mavisi, adsorpsiyon.

ABSTRACT

Polyaniline (PANI) was synthesised by the chemical oxidative polymerisation of aniline in 1 M hydrochloric acid medium using ammonium persulfate as the oxidant at room temperature, yielding the conducting emeraldine salt form of the polymer as a dark powder. The HCl-doped PANI was then evaluated as an adsorbent for the cationic dye methylene blue (MB^+) from aqueous solution. The effect of the initial solution pH was examined over the range 2-10 at a fixed MB^+ concentration of 100 ppm, and the highest uptake was obtained at pH 3. Concentration-dependent adsorption was subsequently studied at this pH over an initial concentration range of 10-1000 ppm at an adsorbent dose of 0.1 g/10 mL. The experimental isotherms were fitted to the Langmuir, Freundlich and Temkin models; agreement was significant for all three, with the Langmuir model providing the best description (R^2 = 0.991) and defining a monolayer capacity of 0.07 mol kg^{-1} (≈22 mg g^{-1}) together with a Langmuir constant of 1429 L mol^{-1}. The Freundlich heterogeneity parameter (β = 0.49) and the Temkin energy factor (A_T = 30.82 × 10^3 L mol^{-1}) were also derived. Gibbs free energy changes calculated from the Langmuir and Temkin constants were -17.99 and -25.61 kJ mol^{-1}, respectively, indicating that MB^+ adsorption on HCl-doped PANI proceeds spontaneously. Assessment by the Langmuir kinetic approach gave $\Theta_{e,theor} - k_1/k_2 < 0$, showing that the process follows first-order rate behaviour. The results demonstrate that HCl-doped PANI, without any support or composite modification, is an effective adsorbent for cationic dye removal.
Keywords: Polyaniline, HCl doping, oxidative polymerisation, methylene blue, adsorption.

1. INTRODUCTION

Rapid industrialisation and urban growth have intensified the discharge of coloured effluents into natural water bodies, and the textile sector is among the largest contributors to this burden (Tripathi et al., 2023). Synthetic dyes are designed to resist fading and consequently resist biodegradation as well; once released, they persist in aquatic systems, reduce light penetration and dissolved oxygen levels, and disturb photosynthesis and the wider aquatic food chain (Hama Aziz et al., 2024; Tripathi et al., 2023). Dye-bearing wastewater must therefore be treated before it reaches receiving water.

Methylene blue (MB^+, $C_{16}H_{18}N_3SCl$) is a cationic thiazine dye first synthesised in 1876 and still one of the most widely used colouring and staining agents in the textile, paper and leather industries (Nguyen et al., 2022). Its strong absorption near 665 nm makes it a convenient model adsorbate, but its environmental profile is far from benign. MB^+ has been described as a potentially carcinogenic pollutant, and exposure has been associated with skin irritation, vomiting, headache, elevated blood pressure and fever (Nguyen et al., 2022); prolonged contact has likewise been linked to nausea and dizziness (Duhan & Kaur, 2020). MB^+ is thus a representative and well-justified target for cationic dye removal studies.

A wide range of technologies have been applied to dye-laden effluents, including coagulation-flocculation, membrane filtration, advanced oxidation, photocatalysis and biological degradation. In practice these routes are frequently limited by incomplete removal, high energy or reagent demand, sludge generation and the formation of secondary by-products (Hama Aziz et al., 2024; Tripathi et al., 2023). Adsorption remains the most widely preferred alternative because it is operationally simple, comparatively inexpensive, adaptable to different effluent compositions, and does not generate toxic degradation intermediates; spent adsorbents can also often be regenerated and reused (Hama Aziz et al., 2024). The efficiency of any adsorption system, however, is governed by surface chemistry and surface charge of the solid phase, which in turn dictate the electrostatic, ion-exchange and complexation contributions to uptake (Mert & Ulusoy, 2024).

Among candidate adsorbents, polyaniline (PANI) has attracted sustained attention. It is prepared straightforwardly by chemical oxidative polymerisation of aniline in acidic medium using ammonium persulfate as oxidant, the monomer is inexpensive, and the resulting polymer shows good environmental and thermal stability (Bednarczyk et al., 2021). PANI exists in three oxidation states, of which the half-oxidised emeraldine is of primary interest: protonation of emeraldine base with a protonic acid converts the insulating polymer into the conducting emeraldine salt, and hydrochloric acid is the most commonly employed dopant for this purpose (Bednarczyk et al., 2021). From an adsorption standpoint, the value of PANI lies in the density and variety of its interaction sites. The backbone carries amine and imine nitrogen atoms alongside aromatic rings, so that electrostatic attraction, π-π stacking and hydrogen bonding can all operate simultaneously (Duhan & Kaur, 2020; Samadi et al., 2021). Critically, the surface charge of PANI is not fixed: it can be tuned through doping and de-doping or through the pH of the medium, which makes protonation state a design variable rather than a fixed property (Samadi et al., 2021).

Several studies have exploited this behaviour for MB^+. Duhan and Kaur (2020) reported 91% MB^+ removal by polyaniline nanofibre base, with data following the Freundlich isotherm and pseudo-second-order kinetics. Djellali et al. (2022) combined DFT calculations with batch experiments on doped and non-doped PANI and concluded that π-π stacking and van der Waals forces dominate, with an adsorption energy of about 14 kJ mol^{-1} indicating a purely physical mechanism. Bensedira et al. (2022) evaluated PANI and PANI/SiO_2 and again found pseudo-second-order kinetics across the temperatures studied. Chloride-doped PANI has also been used as a coating: Mohammad and Atassi (2020) showed that depositing it on electrospun polylactic acid and polyacrylonitrile membranes improved both adsorption performance and reusability relative to the uncoated supports. More recently, Mehennaoui et al. (2026) compared HCl- and H_2SO_4-doped Luffa/PANI composites and found that although the HCl-doped material had the larger BET surface area, the sulfate-doped one adsorbed more MB^+, a direct demonstration that dopant-controlled surface chemistry can outweigh total porosity. The pH sensitivity of these systems is equally well established; Galloni et al. (2022) reported a point of zero charge near 2.87 for PANI-modified adsorbents, below which imine nitrogens are readily protonated and the surface becomes positively charged.

Despite this body of work, most reports concern PANI composites, coatings or the de-doped base form. Systematic adsorption data for plain HCl-doped PANI, the emeraldine salt as directly obtained from synthesis, without any support or secondary component, remain comparatively scarce, particularly when

pH dependence, multi-model isotherm analysis, isotherm-derived thermodynamics and kinetic order assessment are treated together.

The present work addresses this gap. PANI was synthesised by chemical oxidative polymerisation in hydrochloric acid medium and evaluated as an adsorbent for MB. The effect of initial pH was examined over the range 2-10 at a fixed MB concentration of 100 ppm to identify the optimum working pH. Concentration-dependent adsorption was then studied at that pH over 10-1000 ppm, and the experimental isotherms were fitted to the Langmuir, Freundlich and Temkin models. Gibbs free energy changes were calculated from the energy-related constants of the Langmuir (K_L) and Temkin (A_T) models, and the reaction order was assessed using the Langmuir kinetic approach with parameters derived from the isotherm analysis.

2. MATRIALS AND METHOD

2.1 Chemicals

Aniline (ACS reagent) was purchased from Sigma-Aldrich and pre-distilled before use. Ammonium persulfate (APS, ACS reagent) and hydrochloric acid (HCl, ACS reagent) were obtained from Sigma-Aldrich and used as received. Methylene blue (MB^+, $C_{16}H_{18}ClN_3S{\cdot}3H_2O$) was supplied by Biomatic. Sodium hydroxide (Kimetsan) and HCl were used for pH adjustment. All solutions were prepared with distilled water.

2.2. Synthesis of HCl-doped PANI

PANI was synthesised at room temperature by chemical oxidative polymerisation. Polymerization was carried out in a 250-ml three-neck pear-shaped reactor. After adding 5 g of aniline to 180 mL of 1 M HCl, the mixture was transferred to the reactor. 12.25 g of APS (APS/aniline molar ratio: 1) was dissolved in 20 mL of 1 M HCl and then added to the reaction mixture via a dropping funnel over a period of 20 minutes. Due to the exothermic reaction occurring during the addition, the cooling jacket surrounding the reactor was cooled, and the reaction continued at 25°C for 24 hours using a magnetic stirrer at 500 rpm. The reactor was then drained, and the resulting PANI was filtered through filter paper and washed with distilled water. After washing, the PANI was dried in an oven at 40°C for 1 day; upon weighing, the reaction yield was calculated to be 100.5 ± 0.5%. The resulting dark powder, corresponding to the chloride-doped emeraldine salt form of PANI, was ground and stored in a closed container for use as adsorbent. No de-doping step was applied, so that the polymer was retained in its protonated, HCl-doped state throughout.

2.3. Characterisation

The molecular structure of the synthesised polymer was examined by Fourier transform infrared spectroscopy (FTIR) between 4000 and 500 cm^{-1}. Samples were mixed with an appropriate amount of KBr and compressed into pellets prior to measurement. The spectra were inspected for the characteristic benzenoid and quinonoid ring-stretching bands of PANI, for the C-Cl stretching vibration arising from the dopant anion, and for the broad electronic band associated with charge delocalisation along the protonated backbone, all of which serve as evidence for successful chloride doping.

2.4. Adsorption experiments

All adsorption studies were carried out in batch mode at room temperature using an adsorbent dose of 0.1 g per 10 mL of solution, with a contact time of 24 h and intermittent stirring. Equilibrium MB^+ concentrations were determined spectrophotometrically by recording the absorbance of the equilibrium solutions at 665 nm against a distilled water blank, and concentrations were calculated from a calibration curve prepared from MB^+ standards.

2.4.1. Effect of pH

The influence of the initial solution pH on MB^+ uptake was investigated over the range pH 2-10 at a constant initial dye concentration of 100 ppm. The pH of each solution was adjusted with 0.1 M HCl and/or 0.1 M NaOH before contact with the adsorbent.

2.4.2. Effect of concentration (isotherms)

Concentration-dependent adsorption was studied at the pH giving maximum uptake (pH 3) using initial MB^+ concentrations between 10 and 1000 ppm. The adsorbed amounts, Q (mol kg^{-1}), were calculated from Eq. (1);

$$Q = \left[\frac{C_i - C_e}{m}\right] V \quad (1)$$

where; Q (mol kg^{-1}) amount of adsorbed substance, C_i and C_e (mol L^{-1}) initial and equilibrium concentrations of the adsorbed species, m (kg) mass of the adsorbent and V (L) solution volume.

2.4.3. Evaluation of the data

The experimental isotherms obtained were evaluated using the Langmuir, Freundlich, and Temkin models. The Langmuir model is given by Eq. (2), where "X_L" represents the adsorption capacity (Langmuir monolayer capacity) and "K_L" represents the Langmuir constant related to the adsorption energy (L mol^{-1}).

$$Q = \frac{K_L X_L C_e}{1 + K_L C_e} \quad (2)$$

The Freundlich adsorption model, Eq. (3), is related to X_F, which is associated with capacity, and β ($0 < \beta < 1$), defined as the heterogeneity of the adsorbent surface. According to the Freundlich model, a small β value indicates a more heterogeneous adsorbent surface.

$$Q = X_F C_d^{\beta} \quad (3)$$

The Temkin model, Eq. (4), includes the "A_T" factor related to adsorption energy, which takes into account the interaction between the adsorbent and the adsorbate; according to the model, the heat of adsorption possessed by the molecules decreases linearly with adsorption as a result of adsorbate-adsorbate interactions in the adsorption layer (on the surface). "b" in the model is the Temkin isotherm constant.

$$Q = \frac{RT}{b} \ln(A_T C_e) \quad (4)$$

Gibbs free energy changes were derived from the energy-related constants of the two applicable models, using for the Langmuir isotherm Eq. (5), and for the Temkin isotherm Eq. (6).

$$\Delta G = -RT \ln K_L \quad (5)$$
$$\Delta G = -RT \ln A_T \quad (6)$$

The Langmuir kinetic model is a theoretical model developed using a differential equation that includes first- and second-order rate terms; the Langmuir adsorption parameters were used in the modeling. Experimental $\Theta_{e,d}$ loading rate is found using the Eq. (7)

$$\Theta_e = \frac{C_0 - C_e}{X_L D} \quad (7)$$

where 'C_0' ve 'C_e' initial and equilibrium concentrations, 'X_L' maximum adsorbent capacity, 'D' indicates the adsorbent dose.

The theoretical filling ratio, $\Theta_{e,k}$, is determined using Eq. (8).

$$\Theta_{e,k} = \frac{K_L(X_L D + C_0) + 1 - \sqrt{K_L^2 (C_0 - X_L D)^2 + 2K_L(C_0 + X_L D) + 1}}{2K_L X_L D} \quad (8)$$

where "K_L" is the adsorption distribution coefficient determined from the Langmuir model.

The ratio of the rate constants in the Langmuir kinetic model is determined using Eq. (9).

$$\frac{k_1}{k_2} = \frac{\sqrt{K_L^2 (C_0 - X_L D)^2 + 2K_L(C_0 + X_L D) + 1}}{K_L X_L D} \quad (9)$$

Adsorption kinetics are first-order when $k_1/k_2 \geq \theta_e$, second-order only when $k_1/k_2 << \theta_e$, and hybrid (first- and second-order) when $k_1/k_2 < \theta_e$.

3. RESULTS and DISCUSSION

3.1. Characterization

The reaction mechanism for the product obtained by the oxidation of aniline with ammonium persulfate in a 1 M HCl medium is shown in Figure 1. Chemical oxidative polymerization carried out in a strongly acidic medium leads to the formation of linear chains, with aniline units primarily linked in the para position. During polymerization, protons present in the medium protonate the imine nitrogens, creating polaron centers along the chain, and Cl^- ions are incorporated into the structure as counterions that balance these positive centers. The resulting dark-colored powder therefore corresponds to the conductive emeraldine salt form rather than the insulating emeraldine base. The calculation of the reaction yield as 100.5 ± 0.5%, based on the aniline mass, also indirectly supports this finding. Since the contribution of the Cl^- counterion is added to the product mass, it is an expected result that the apparent yield for doped PANI exceeds 100%.

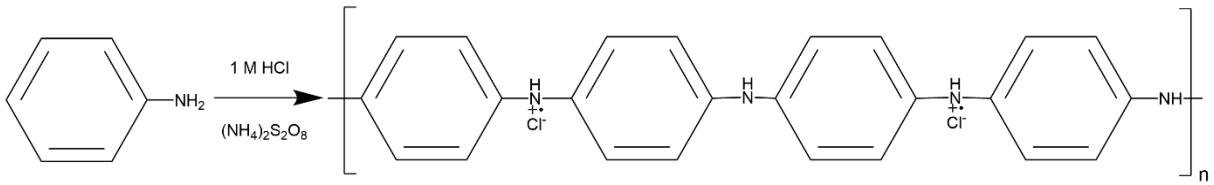

Figure 1. HCl doped Polyaniline Synthesis

The molecular structure of the synthesized polymer was examined using FTIR spectroscopy, and the spectrum is presented in Figure 2. The broad band around 3450 cm^{-1} corresponds to the N–H stretching vibration overlapping with the O–H stretching vibration of moisture trapped in the structure, while the weak band at 3025 cm^{-1} originates from the aromatic C–H stretching vibration. The intense bands at 1580 and 1490 cm^{-1} correspond to the quinoid (Q) and benzenoid (B) ring stretching vibrations, respectively.

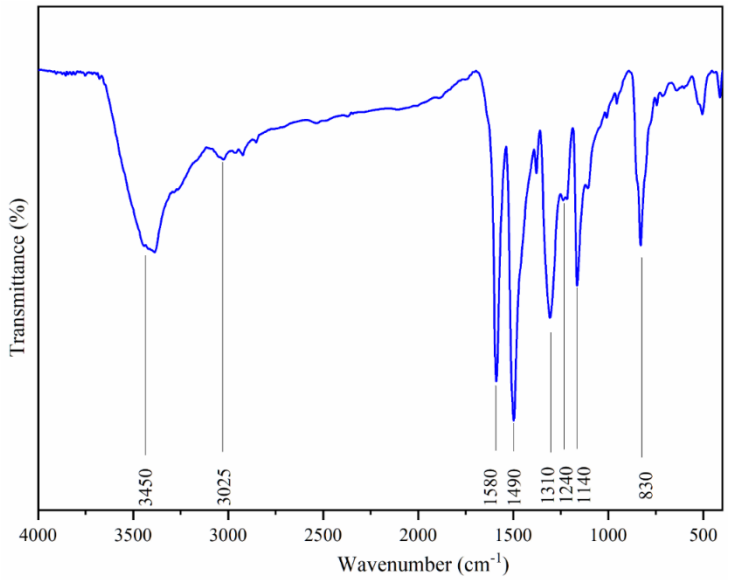

Figure 2. FTIR spectrum of HCl doped PANI

The most direct evidence of doping comes from the bands at 1310, 1240, and 1140 cm^{-1}(Tang et al., 1988; Trchová & Stejskal, 2011). While the band at 1310 cm^{-1} is associated with π-electron delocalization induced by protonation, the band at 1240 cm^{-1} corresponds to the C–N^+• stretching vibration in the polaron structure and is considered the characteristic band of the conductive protonated form. The broad and intense band observed at 1140 cm^{-1} belongs to the –NH^+= vibrational mode of charged units of the form Q=NH^+–B or B–NH^+•–B. The intensity of this band increases with the degree

of protonation and is evaluated as a measure of the presence of positive charges along the chain. The observation of these three bands at distinct intensities indicates that Cl^- doping was successfully achieved and that the polymer is at a high level of protonation. The band at 830 cm^{-1} originates from the out-of-plane C–H bending vibration of two adjacent hydrogen atoms in the 1,4-disubstituted benzene ring and confirms that para bonding predominates along the chain(Trchová & Stejskal, 2011). The FTIR findings confirm that the form of the synthesized material used in the adsorption experiments is emeraldin salt.

3.2. Adsorptive features of HCl-doped PANI for MB^+ adsorption

3.2.1. Adsorption dependence on pH

The effect of initial pH on MB^+ adsorption was investigated in the pH range of 2–10 at a dye concentration of 100 ppm, and the results are presented in Figure 3.

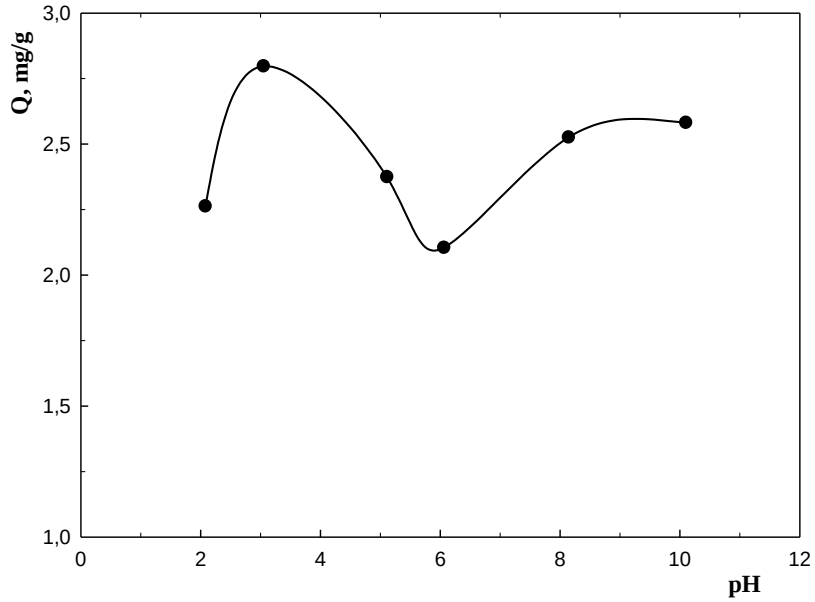

Figure 3. The effect of pH on MB^+ adsorption

The adsorbed amount varied between 2.10 and 2.80 mg g^{-1} across the entire range. This narrow range indicates that pH is not the sole determining factor in the system under study and, consequently, that adsorption is not predominantly electrostatic in nature. Djellali et al. (2022) reported that the binding of MB^+ to PANI is governed by π–π stacking and van der Waals forces, with an interaction energy of approximately 14 kJ mol^{-1}. These interactions between the aromatic backbone and the phenothiazine ring of the dye are relatively independent of the ambient pH, and the limited variation observed is consistent with this mechanism.

However, the curve is not monotonic; a maximum (2.80 mg g^{-1}) is observed at pH 3, a minimum (2.10 mg g^{-1}) at pH 6, and a second increase (2.53–2.59 mg g^{-1}) in the pH 8-10 range. This two-region behavior can be explained by changes in the adsorbent's protonation state with pH. In the acidic region, the polymer adopts the emeraldine salt form. Under these conditions, where conjugation and chain planarity are at their highest, the accessible surface area for π–π interactions is the widest. The decrease observed at pH 2 can be attributed to the increased H^+ concentration strengthening the repulsion between the protonated surface and the cationic dye, as well as the increase in ionic strength resulting from acid addition, which creates charge screening. The minimum around pH 6 corresponds to a transition region where partial de-doping begins, the surface charge is largely neutralized, and, conversely, free imine/amine regions have not yet formed.

The subsequent increase in the alkaline region is explained by the conversion of the emeraldin salt to emeraldine base. The unpaired electron pairs of the imine and amine nitrogens released as a result of de-doping become capable of forming hydrogen bonds. The surface acquires a net negative charge, making it electrostatically attractive to the cationic MB^+ (Galloni et al., 2022; Samadi et al., 2021). This

observation is consistent with the findings of Djellali et al. (2022), who found alkaline conditions to be superior to acidic conditions.
Isotherm studies were conducted at pH 3, where both the highest adsorption was achieved and the adsorbent retained its emeraldine salt identity.

3.2.2. The adsorption isotherms

The experimental isotherm obtained at pH 3 over an initial concentration range of 10–1000 ppm and its agreement with the models are shown in Figures 4–6, and the calculated parameters are presented in Table 1.

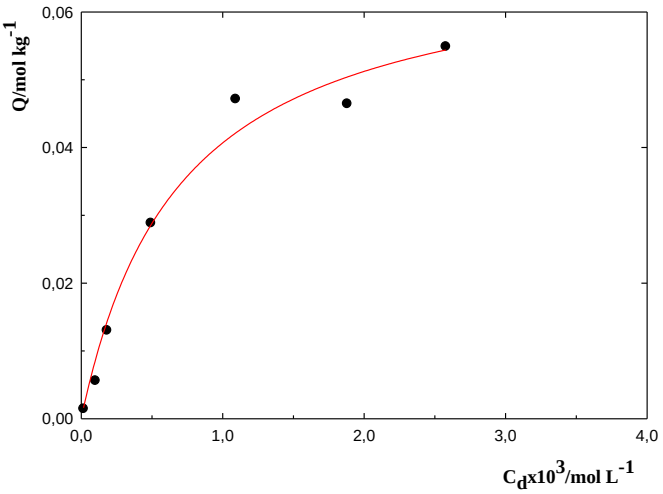

Figure 4. Compatibility of the experimentally obtained MB^+ adsorption isotherms to Langmuir model {$[MB^+]0$=10-1000 ppm, D =0.1 g/10 mL}

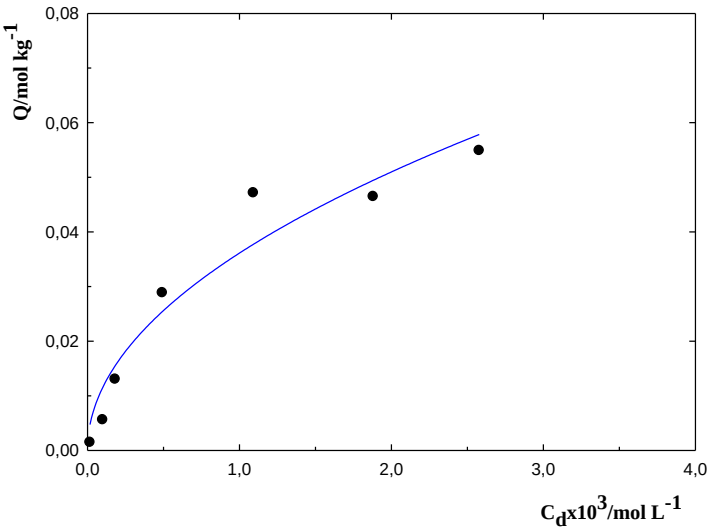

Figure 5. Compatibility of the experimentally obtained MB^+ adsorption isotherms to Freundlich model

{$[MB^+]_0$=10-1000 ppm, D =0.1 g/10 mL}

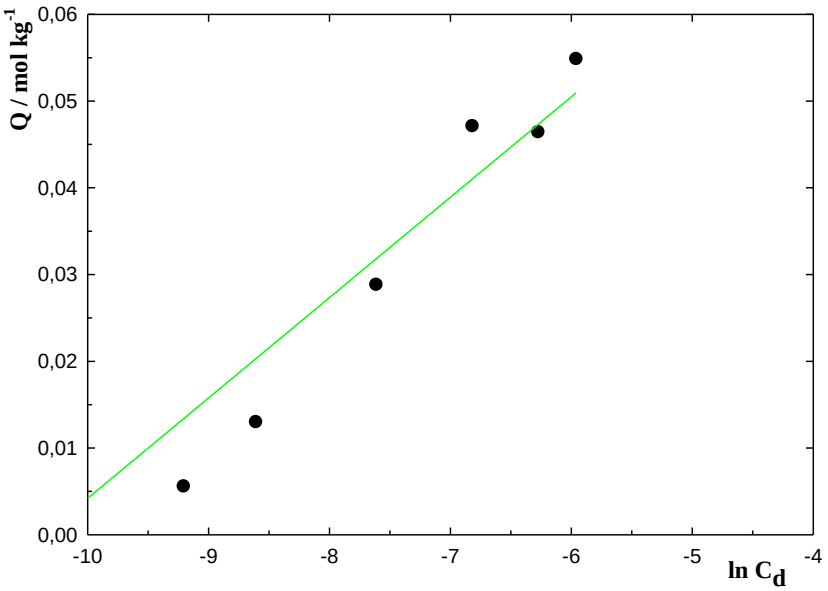

Figure 6. Compatibility of the experimentally obtained MB^+ adsorption isotherms to Temkin model {[MB^+]0=10-1000 ppm, D =0.1 g/10 mL}

Table 1. Langmuir, Freundlich, and Temkin parameters for adsorption of MB^+ onto HCl doped PANI

Langmuir		Freundlich		Temkin	
X_L/molkg^{-1}	0.07	X_F	1.12	A_T/Lmol^{-1}x10^{-3}	30.82
K_L/Lmol^{-1}	1429	β	0.49		
R^2	0.991	R^2	0.970	R^2	0.955

The experimental isotherm exhibits a Type-I (Giles L-type) character, showing a steep increase at low equilibrium concentrations followed by a plateau. This behavior indicates that MB^+ has a high affinity for the adsorbent surface (Thommes et al., 2015). The fit was found to be statistically significant for all three models. The Langmuir model provided the best fit (R^2 = 0.991; Freundlich 0.970; Temkin 0.955). From the Langmuir model, the monolayer capacity X_L was calculated as 0.07 mol kg^{-1} (≈22 mg g^{-1}) and the constant related to the adsorption energy, K_L, as 1429 L mol^{-1}. The high K_L value indicates a strong adsorbent-adsorbate interaction and that the surface is effectively filled even at low concentrations. The superiority of the Langmuir model suggests that adsorption occurs as a monolayer in a limited number of regions that are energetically close to one another.

The β value of 0.49 obtained from the Freundlich model falls within the range $0 < \beta < 1$. This value indicates that adsorption is thermodynamically favorable. The fact that β is significantly less than 1, however, suggests the presence of a certain degree of heterogeneity on the surface. When considered alongside the better fit provided by the Langmuir model, this situation can be interpreted as indicating the presence of a dominant single binding site type (protonated nitrogen centers and adjacent aromatic rings) alongside sites with different energies whose contribution remains secondary. The fact that the Temkin model provides the poorest fit indicates that the interactions between the adsorbed MB^+ molecules and the resulting linear decrease in the adsorption enthalpy are not the primary factors governing the process.

The Gibbs free energy changes calculated from the model constants related to the adsorption energy are presented in Table 2.

Table 2. Thermodynamic parameters related to MB^+ adsorption

Langmuir isotherm 'K_L'		**Temkin isotherm 'A_T'**	
(ΔG=-RTlnK_L)/kJmol^{-1}	-17.99	ΔG/kJmol^{-1}	-25.61

A value of $\Delta G = -17.99$ kJ mol^{-1} was obtained from the Langmuir constant, and $\Delta G = -25.61$ kJ mol^{-1} from the Temkin constant. The difference between the two values stems from the different energy definitions used by the models. While K_L is an adsorption equilibrium constant, A_T is the Temkin binding factor, which incorporates the adsorbent-adsorbate interaction. The fact that both values are negative indicates that the adsorption occurs spontaneously. The fact that their absolute values remain below 40 kJ mol^{-1} suggests that the process proceeds primarily through physical interactions and ion exchange rather than chemical bond formation. This result is consistent with that reported by Djellali et al. (2022), who reported an interaction energy of approximately 14 kJ mol^{-1} for MB^+ adsorption on PANI and attributed the mechanism to π–π stacking and van der Waals forces.

The kinetic order was evaluated using the approach of Liu and Shen (2008) based on Langmuir isotherm parameters, and the results are presented in Table 3.

Table 3. Adsorption kinetics parameters derived from the Langmuir kinetic model for MB^+ adsorption onto HCl doped PANI
{$[MB^+]_0$=1.560x10^{-3} mol L^{-1}, D=0.01 kg L^{-1}

Material	**C_ex10^4**	**$\Theta_{e,exp}$**	**$\Theta_{e,theor}$**	**(k_1/k_2)**	**k_1/k_2 - $\Theta_{e,theor}$**		**Langmuir model**
HCl doped PANI		10.90	0.672	0.617	2.994	>0	first-order

At an initial concentration of 500 ppm, the experimental surface occupancy $\Theta_{e,d}$ was found to be 0.672, while the theoretical occupancy $\Theta_{e,k}$ calculated from the model was 0.617. The closeness of these two values indicates that the Langmuir parameters consistently represent experimental behavior. The rate constant ratio $k_1/k_2 = 2.994$, which is greater than the $\Theta_{e,k}$ value. This condition indicates that the Langmuir kinetics have been reduced to a first-order rate equation, implying that the adsorption exhibits first-order kinetics.
The results obtained in this study demonstrate that HCl-doped PANI, without any support or modification, functions as a standalone adsorbent for the removal of cationic dyes.

4. CONCLUSIONS

In this study, polyaniline was synthesized via chemical oxidative polymerization with ammonium persulfate in a 1 M HCl solution and evaluated as an adsorbent for the cationic dye methylene blue directly in the form of emeraldine salt, without undergoing a de-doping process. FTIR analysis confirmed that the synthesized material exists in the form of a conductive salt with a high degree of protonation, as evidenced by the quinone/benzene bands at 1580/1490 cm^{-1}, polaron-derived bands at 1310, 1240, and 1140 cm^{-1}, and the absence of the emeraldine base band at 1378 cm^{-1}.
The pH dependence of adsorption exhibited a two-region behavior. The fact that the adsorbed amount varied only between 2.10 and 2.80 mg g^{-1} in the pH range of 2-10 indicated that the process was not predominantly electrostatic in origin. While π–π interactions were determined to be the decisive factor for the maximum adsorption of emeraldine salt in the acidic region (pH 3; 2.80 mg g^{-1}) under conditions where the salt was preserved, the second peak in the alkaline region was attributed to the surface becoming electrostatically favorable for cationic dyes as a result of partial de-doping.
The isotherms obtained at pH 3 are of Type-I (Giles L-type) character and showed a good fit with all three models, with the Langmuir model providing the best fit ($R^2 = 0.991$). The monolayer capacity was determined to be 0.07 mol kg^{-1} (≈22 mg g^{-1}), and the Langmuir constant was found to be 1429 L mol^{-1}. The free energy changes calculated from the Langmuir and Temkin constants (-17.99 and -25.61 kJ mol^{-1}) indicate that adsorption occurs spontaneously, while the fact that the absolute values remain below 40

kJ mol^{-1} suggests that the process proceeds via physical interactions and ion exchange. Using the Liu and Shen approach, the fulfillment of the condition $k_1/k_2 = 2.994 > \Theta_{e,k} = 0.617$ revealed that the kinetics were reduced to a first-order rate equation.

The findings demonstrate that HCl-doped PANI, which contains no support material or composite modification, functions as a standalone adsorbent for the removal of cationic dyes. To translate these findings into practical applications, the characterization of surface area and morphology, the determination of enthalpy and entropy changes at different temperatures, and the assessment of reusability performance are issues that must be addressed in subsequent stages.

ABSTRACT
The safety risks and limited electrochemical stability of flammable liquid electrolytes remain major barriers to the development of high-energy-density lithium batteries. Oxide-based solid electrolytes offer a promising route toward safer solid-state batteries because of their nonflammability, mechanical rigidity, broad electrochemical stability, and atmospheric tolerance. This study evaluates the lithium-ion transport mechanisms, material classes, processing strategies, and practical limitations of oxide solid electrolytes. Garnet-type LLZO and LLZTO, NASICON-type LATP and LAGP, perovskite-type LLTO, and LISICON-related compositions are comparatively examined. Particular attention is given to the effects of crystal symmetry, aliovalent doping, lithium vacancies, grain-boundary chemistry, and ceramic processing on ionic conductivity. As an experimental case study, Ta-doped $Li_{6.4}La_3Zr_{1.4}Ta_{0.6}O_{12}$ was prepared by a conventional solid-state route involving wet ball milling at 350 rpm for 12 h, calcination at 950 °C for 12 h, uniaxial pressing at 300 MPa, and sintering at 1175 °C for 6 h. X-ray diffraction revealed progressive phase evolution from the precursor mixture toward a predominantly garnet-type LLZTO structure. The principal garnet-related reflections were retained after final sintering, while minor additional reflections indicated possible secondary phases. Although the pattern was consistent with Ta-stabilized cubic LLZTO, definitive structural confirmation requires reference-pattern matching and Rietveld refinement. Overall, the findings demonstrate that the performance of oxide solid electrolytes depends on the combined optimization of crystal chemistry, thermal processing, microstructure, and electrode–electrolyte interfaces.

1. INTRODUCTION
Lithium-ion batteries (LIBs) have become the leading energy-storage technology for electric vehicles because they contribute to lower CO_2 emissions, improved energy efficiency, and reliable rechargeable operation. Their use is not limited to transportation; LIBs are also extensively employed in portable electronic devices, stationary grid-storage systems, and numerous other applications. Their widespread adoption is associated with several advantageous characteristics, including high specific power, low self-discharge, operation over a relatively broad temperature range, absence of a pronounced memory effect, long cycle life, and comparatively favorable environmental performance. Nevertheless, commercially available LIBs continue to face important challenges concerning safety and achievable energy density. Conventional LIBs generally employ liquid electrolytes containing organic solvents that provide high ionic conductivity. However, the volatility, flammability, and toxicity of these solvents create substantial safety and environmental concerns. Electrolyte leakage, internal short circuits, fire, explosion, and uncontrolled lithium-dendrite formation are among the potential failure mechanisms that may threaten both human health and environmental safety (Bakar et al., 2023)
The energy density attainable with present-day LIB technology remains insufficient for some emerging applications. State-of-the-art systems typically deliver gravimetric energy densities of approximately

210–235 Wh kg^{-1} and volumetric energy densities of about 400–630 Wh L^{-1}. Therefore, the broader electrification of next-generation transportation, portable electronics, and large-scale energy-storage systems will require substantial improvements in both gravimetric and volumetric energy density (Liu and Li 2022, Bills et al. 2020). To address these limitations, considerable research has focused on developing advanced materials for the principal components of LIBs, including anodes, cathodes, and electrolytes (Wieczorek et al. 1989).

Among the proposed strategies, replacing conventional liquid or gel electrolytes with solid ion-conducting materials is considered one of the most promising approaches. Solid-state batteries (SSBs) can provide higher energy density, improved thermomechanical and electrochemical stability, and lower flammability than conventional LIBs, thereby enabling safer, more robust, and more compact energy-storage systems. Their cell architecture also differs fundamentally from that of liquid-electrolyte batteries. In an SSB, the solid electrolyte simultaneously conducts lithium ions between the electrodes and physically separates the cathode from the anode. Consequently, it can perform the functions of both the electrolyte and the separator, eliminating the need for the additional porous separator typically used in conventional LIBs (Bates et al. 2022).

Solid electrolytes are commonly grouped into sulfides, oxides, polymers and composites. Sulfide conductors can reach room-temperature ionic conductivities comparable to liquid electrolytes and are readily densified by pressure, yet many are sensitive to moisture and can release H_2S. Polymer electrolytes offer flexibility and excellent interfacial conformity but often show limited room-temperature conductivity and reduced mechanical strength at temperatures where segmental motion becomes rapid. Oxide electrolytes are nonflammable and usually more stable in air and at elevated temperature. Their main disadvantages are brittleness, high processing temperatures, difficult solid-solid contact, and large interfacial resistance (Biçer et al. 2025). The principal differences among oxide-, sulfide-, and polymer-based solid electrolytes in terms of ionic conductivity, air stability, mechanical properties, interfacial contact, processing requirements, moisture sensitivity, lithium-metal compatibility, and manufacturing scalability are summarized in Table 1.

Table 1. Comparison of oxide, sulfide, and polymer solid electrolytes

Property	**Oxide**	**Sulfide**	**Polymer**
Ionic conductivity	High	Very high	Moderate
Air stability	High	Low	High
Mechanical strength	High	Moderate	Low
Interfacial contact	Difficult	Excellent	Excellent
Processing temperature	High	Low	Low
Moisture sensitivity	Low	High	Low
Li-metal compatibility	Variable	Variable	Variable
Manufacturing scalability	Challenging	Promising	Promising

In oxide-based solid electrolytes, macroscopic ionic conductivity is governed by the combined effects of crystal structure, defect chemistry, phase purity, grain-boundary properties, and ceramic microstructure. Processing conditions are therefore as important as chemical composition because calcination, sintering, and densification directly influence the continuity of Li^+-transport pathways and the overall resistance of the electrolyte (Famprikis et al. 2019).

In addition to bulk and grain-boundary transport, the electrochemical performance of oxide solid electrolytes is strongly governed by their contact with the electrodes. As illustrated in Figure 1, solid

electrolyte–electrode interfaces may undergo parasitic redox, chemical, and electrochemical reactions, resulting in the formation of resistive interphases that obstruct Li^+ transport. This issue is particularly important for oxide electrolytes because their rigid ceramic nature can produce limited solid–solid contact and high interfacial resistance, despite their generally favorable thermal and chemical stability. Achieving stable battery operation therefore requires chemically compatible electrode–electrolyte combinations, kinetically stabilized interfaces, or artificial protective interlayers that suppress undesirable reactions while preserving continuous Li^+-transport pathways. Accordingly, the practical performance of oxide solid electrolytes must be evaluated through the combined consideration of crystal structure, defect chemistry, ceramic processing, microstructure, and interfacial engineering.

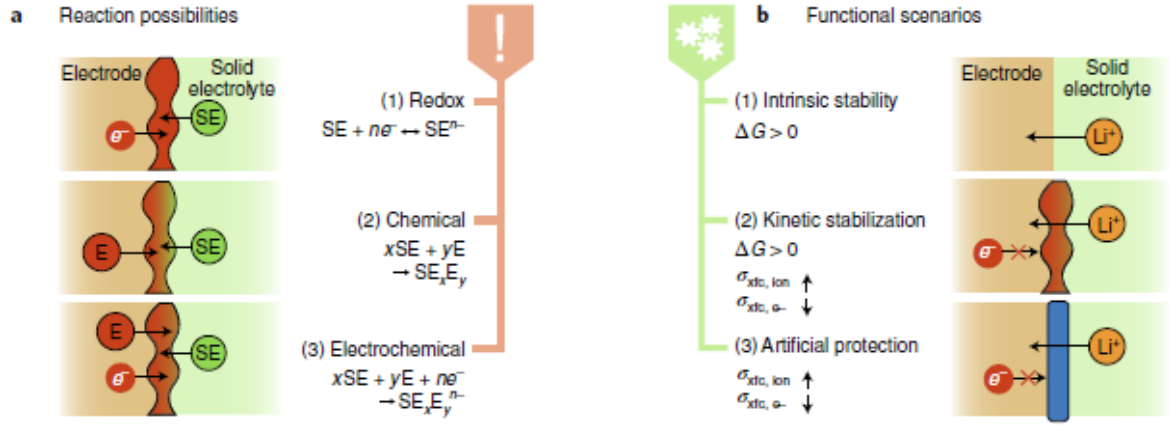

Figure 1. Possible reaction pathways and stabilization strategies at solid electrolyte–electrode interfaces**.** (a) Parasitic redox, chemical, and electrochemical reactions that may occur at the solid electrolyte–electrode interface depending on the thermodynamic driving force. (b) Interface-engineering strategies based on intrinsic compatibility, kinetic stabilization, and artificial protective interlayers. An effective interface should enable continuous Li^+ transport while suppressing electron transfer and the interdiffusion of chemical species. SE and E represent species in the solid electrolyte and electrode, respectively (Famprikis et al. 2019).

This review provides a systematic evaluation of oxide-based solid electrolytes by integrating three closely related aspects: lithium-ion transport mechanisms, structural classifications, and materials-processing strategies. The crystal chemistry, defect structure, ionic-conduction pathways, and principal limitations of garnet-, NASICON-, perovskite-, and LISICON-type electrolytes are comparatively assessed, with particular emphasis on LLZO and Ta-substituted LLZTO. The review further examines how phase composition, dopant chemistry, grain-boundary characteristics, densification, and electrode–electrolyte interfaces collectively determine the measured ionic conductivity and cell-level electrochemical performance. By establishing relationships among composition, processing, structure, and functionality, this study aims to identify the critical parameters required to translate the favorable intrinsic properties of oxide electrolyte powders into dense, low-resistance, and operationally stable solid-state battery architectures.

1.1. Fundamentals of solid-state oxide electrolytes

1.1.1. Ionic Transport Mechanisms

Lithium-ion transport in crystalline oxide electrolytes occurs through thermally activated hopping between energetically accessible crystallographic sites. Ionic conductivity depends on the concentration and mobility of charge carriers, the availability of vacant sites, the connectivity of migration pathways, and the dimensions of structural bottlenecks. Although vacancies can facilitate Li^+ migration, excessive defect concentrations may promote defect association, local ordering, or lattice distortion and thereby increase the migration barrier (Geiger et al. 2011).

Lithium-ion transport must be evaluated across multiple length scales. As illustrated in Figure 2, atomic-scale hopping determines the intrinsic mobility of Li^+ ions, whereas crystalline and amorphous regions, grain boundaries, porosity, and secondary phases control transport at the microstructural scale. At the device level, electrode–electrolyte contact and charge-transfer resistance contribute to the overall cell

impedance. Consequently, high intrinsic ionic conductivity within individual grains does not necessarily ensure low total resistance or satisfactory electrochemical performance in a complete cell (Famprikis et al. 2019).

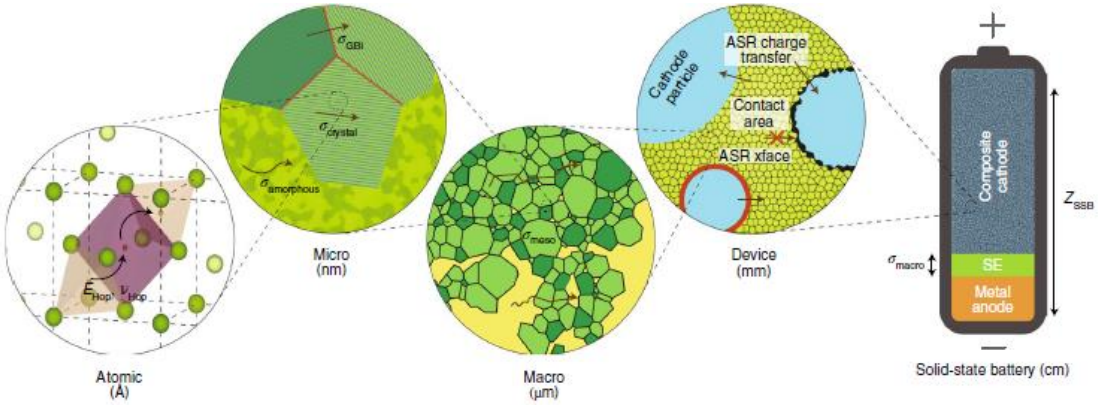

Figure 2. Multiscale lithium-ion transport in solid electrolytes. Li^+ transport extends from atomic-scale hopping to transport through crystalline and amorphous regions, grain boundaries, and macroscopic microstructures. At the device scale, electrode–electrolyte contact and charge-transfer processes collectively determine the overall impedance of the solid-state battery (Famprikis et al. 2019).

1.1.2. Crystal Structure and Lithium-Ion Migration

The crystal structure of oxide solid electrolytes determines the dimensionality and connectivity of Li^+-migration pathways. Garnet electrolytes contain three-dimensional networks of tetrahedral and octahedral Li sites, whereas NASICON, perovskite, and LISICON-type structures enable ion transport through interconnected channels, vacant crystallographic sites, or open tetrahedral frameworks. Three-dimensional pathways are generally less susceptible to local blocking because they provide alternative routes for Li^+ migration.

Crystal symmetry and Li-site occupancy also strongly influence ionic conductivity. In LLZO, the tetragonal phase contains an ordered Li sublattice that restricts ion mobility, while the cubic phase exhibits partially occupied and disordered Li sites, enabling more isotropic and rapid transport. Cubic and tetragonal LLZO are commonly assigned to the Ia–3d and $I4_1/acd$ space groups, respectively. Because peak overlap and secondary phases can complicate XRD interpretation, reliable phase identification should combine structural refinement with complementary techniques such as Raman spectroscopy or solid-state NMR (Umair et al. 2025).

1.1.3. Defects, Vacancies, and Grain Boundaries

Point defects regulate the concentration of mobile Li^+ carriers, whereas grain boundaries and porosity determine whether these ions can move effectively across the entire electrolyte. Aliovalent doping can enhance conductivity by generating Li vacancies; however, dopant segregation, lithium volatilization during sintering, and secondary-phase formation may produce resistive regions at grain boundaries.

Grain-boundary transport is governed by local composition, space-charge effects, defect distribution, and interfacial structure. Lithium-depleted or secondary-phase-rich boundaries can obstruct ion migration, whereas vacancy-rich boundaries without substantial lithium depletion may facilitate transport. Porosity further reduces the number of effective conduction pathways, decreases electrode–electrolyte contact, and may promote lithium-filament penetration. Although densification generally improves total ionic conductivity, excessive sintering can cause abnormal grain growth, pore entrapment, lithium loss, and mechanical degradation. Therefore, defect chemistry, grain-boundary composition, relative density, and mechanical integrity must be optimized together (Gregori et al. 2017; Cheng et al. 2015).

1.1.4. Relationship between Crystal Chemistry and Ionic Conductivity

High ionic conductivity requires a continuous migration network, an appropriate concentration of lithium vacancies, and sufficiently low migration barriers. In LLZO, Al^{3+} and Ga^{3+} preferentially occupy lithium sites, whereas Ta^{5+} and Nb^{5+} primarily substitute for Zr^{4+}. These aliovalent substitutions modify lithium content and site occupancy and can contribute to the stabilization of the highly conductive cubic

structure. However, total conductivity also depends on dopant solubility, site preference, segregation, phase purity, grain-boundary composition, and ceramic density. Therefore, cubic symmetry alone does not guarantee high macroscopic ionic conductivity, and crystal chemistry must be evaluated together with microstructure and processing history (Eggestad et al. 2024).

1.2. Classification of oxide solid electrolytes

1.2.1. Garnet-Type Electrolytes

Garnet-type lithium conductors attracted wide attention after fast lithium transport was reported in $Li_7La_3Zr_2O_{12}$. The Zr-based garnet framework offers high thermal stability and practical compatibility with lithium metal compared with Ti- or Ge-containing oxides that are readily reduced. The central challenge is stabilizing the conductive cubic phase while maintaining high density and low impurity content. Undoped LLZO tends to form a tetragonal, lithium-ordered phase at room temperature when contamination and lithium nonstoichiometry are carefully excluded. Al- and Ga-doped LLZO stabilize the cubic structure by substituting for lithium and creating vacancies. Al is technologically convenient because small amounts can enter the material from alumina crucibles, but uncontrolled contamination undermines compositional reproducibility. Ga can yield high conductivity but may segregate or form Li-Ga-O phases depending on loading and thermal history. Zr-site substitution with Ta^{5+} or Nb^{5+} provides another route to vacancy formation. Ta-doped LLZO can be prepared without intentional Al, and Ta substitution lowers the temperature required to stabilize the cubic modification (Umair et al. 2025).

The nominal composition $Li_{6.4}La_3Zr_{1.4}Ta_{0.6}O_{12}$ is widely used because Ta^{5+} substitution creates 0.6 lithium vacancies per formula unit relative to $Li_7La_3Zr_2O_{12}$. These vacancies suppress long-range lithium ordering and facilitate access to the cubic garnet network. Nevertheless, Ta content must be interpreted together with lithium excess, crucible interaction, and sintering conditions. Loss of lithium can increase secondary-phase formation, while excessive lithium compensation can leave residual Li_2CO_3 or Li-rich phases. X-ray diffraction, elemental analysis, density measurement, and impedance spectroscopy should therefore be evaluated as a single data set. For battery integration, LLZO and LLZTO offer attractive electronic insulation and stiffness but suffer from poor contact with lithium and composite cathodes. The surface rapidly accumulates Li_2CO_3 and LiOH in ambient air. These species reduce the true area of contact and raise interfacial impedance. Surface cleaning can reduce resistance dramatically by restoring lithium wetting. At higher current density, however, microstructural defects and local electronic conduction can still promote internal lithium deposition. Direct observations and modeling show that pores, cracks, grain boundaries, and nonuniform pressure strongly influence failure (Umair et al. 2025).

1.2.2. NASICON-Type Electrolytes

NASICON-type lithium conductors derive from a rigid phosphate framework that provides interconnected three-dimensional channels. LATP, commonly represented near $Li_{1.3}Al_{0.3}Ti_{1.7}(PO_4)_3$, and LAGP, commonly represented near $Li_{1.5}Al_{0.5}Ge_{1.5}(PO_4)_3$, are the most studied compositions. Aliovalent substitution of Al^{3+} for Ti^{4+} or Ge^{4+} increases lithium content and modifies site occupancy. Trivalent substitution has been reported to enhance ionic conductivity and sinterability in lithium titanium phosphate systems (Umair et al., 2025).

LATP offers relatively low raw-material cost and good stability in air, but Ti^{4+} can be reduced in direct contact with lithium metal. The resulting mixed ionic-electronic interphase makes direct use against lithium problematic. Protective interlayers or polymer buffers are therefore required. In addition, LATP ceramics frequently contain resistive grain-boundary phases. Additives may improve densification or remove blocking phases, but they can also narrow the electrochemical window or change mechanical properties. Replacing Ti with Ge improves reduction behavior in some operating windows and can provide high bulk conductivity, but Ge increases material cost and remains susceptible to reduction against lithium. LAGP is often processed through a glass-ceramic route, where controlled crystallization produces the NASICON phase. This route offers compositional homogeneity and the possibility of thin sheets, but conductivity depends strongly on crystallization temperature, grain connectivity, residual glass, and secondary phases. The use of LATP or LAGP is therefore most credible when combined with an interface architecture that prevents direct contact with lithium metal (Umair et al. 2025).

1.2.3. Perovskite-Type Electrolytes

Lithium lanthanum titanate, $Li_{3x}La_{2/3-x}TiO_3$, is the reference perovskite oxide electrolyte. Its A sublattice contains Li^+, La^{3+}, and vacancies, while Ti occupies the B site. Lithium migrates through oxygen-square bottlenecks between neighboring A-site cavities. The original report showed bulk conductivity near 10^{-3} S cm^{-1} at room temperature, but much lower total conductivity in polycrystalline samples (Umair et al. 2025). The difference arises largely from grain-boundary blocking.

LLTO illustrates why bulk conductivity alone is an incomplete screening metric. La-rich or Li-depleted grain boundaries create space-charge barriers, and structural ordering can produce anisotropic transport. Processing methods that increase grain size may reduce the number of boundaries but cannot fully remove chemically blocking boundary layers. Furthermore, Ti^{4+} is reduced by lithium metal, which increases electronic conductivity and destabilizes direct contact. LLTO is consequently more suitable as a protected electrolyte, a component in multilayer structures, or a model system for understanding grain-boundary transport than as an unmodified separator against lithium (Umair et al. 2025).

1.2.4. LISICON and Related Oxide Electrolytes

LISICON denotes a family of lithium superionic conductors based on tetrahedral oxide frameworks. Classical compositions derived from Li_4GeO_4-Li_3O_4 or Li_4SiO_4 solid solutions demonstrate how substitution and interstitial lithium can increase carrier concentration. Their advantages include chemical diversity and comparatively open frameworks. However, many oxide LISICON compositions exhibit room-temperature conductivities below those of optimized garnet, NASICON, or perovskite electrolytes, and some contain reducible or expensive elements. Oxynitride derivatives such as LiPON extend the LISICON concept toward amorphous thin films. LiPON has lower conductivity than leading bulk ceramics but offers exceptional uniformity, negligible grain-boundary pathways, and stable cycling in micrometer-scale thin-film batteries. Its success demonstrates that a moderate conductivity can be acceptable when the electrolyte is extremely thin and interfaces are well controlled. This principle also motivates thin-film processing of garnet and NASICON materials (Umair et al. 2025).

2. MATERIALS AND METHODS

2.1. Synthesis and processing of oxide solid electrolytes

2.1.1. Sol-Gel Processing

Sol–gel synthesis enables the homogeneous mixing of precursor species at the molecular level and generally consists of the following stages: dissolution of metal salts or alkoxides, addition of a complexing agent, control of pH and hydrolysis, sol formation, gelation, aging, drying, organic removal, calcination, powder grinding, pelletization, and final sintering. Compared with conventional solid-state reactions, the shorter diffusion distances can reduce the phase-formation temperature and produce finer, more homogeneous powders. The method also facilitates the uniform distribution of dopant elements throughout the structure. However, product quality strongly depends on precursor chemistry, pH, solvent composition, complexing-agent ratio, gelation conditions, and heat-treatment profile. Incomplete organic decomposition may produce carbon residues, whereas rapid combustion can cause agglomeration and chemical inhomogeneity. Furthermore, the high surface area of sol–gel-derived powders increases their sensitivity to moisture, Li^+/H^+ exchange, and surface carbonate formation. Therefore, although sol–gel processing improves precursor homogeneity and reaction kinetics, controlled calcination, densification, and surface handling remain necessary to obtain phase-pure and highly conductive oxide electrolytes (Kokal et al. 2011).

2.1.2. Hot Pressing

Hot pressing applies uniaxial pressure during heating, allowing densification at lower temperature or shorter dwell time than pressureless sintering. The method can suppress pore growth and produce dense garnet pellets. In hot-pressed cubic LLZO, increasing relative density from approximately 85% to 98% increased total ionic conductivity from about 0.0094 to 0.34 mS cm^{-1}, demonstrating the strong effect of connected porosity (Cheng et al. 2015). Pressure-assisted processing can therefore improve both transport and reproducibility. The limitations are equipment cost, restricted geometry, possible anisotropy, die reactions, and low throughput. Spark-plasma sintering and field-assisted techniques shorten thermal exposure further, but carbon contamination, reduction, and nonuniform current distribution must be considered. Pressure-assisted methods are valuable for mechanistic studies and

high-density components, whereas their role in mass production depends on the achievable area, thickness, and cycle time (Kim et al. 2016)

2.1.3. Tape Casting

Tape casting is attractive because it can produce thin, large-area ceramic sheets continuously. A ceramic powder is dispersed in a solvent with dispersant, binder, and plasticizer; the slurry is cast through a doctor blade and dried to form a flexible green tape. After cutting and lamination, binder burnout and sintering produce the dense electrolyte. Thickness reduction directly lowers area-specific resistance, making tape casting more relevant to practical cells than millimeter-scale pellets. LLZO tape casting is chemically demanding. Protic solvents and moisture can promote Li^+/H^+ exchange, while CO^2 exposure produces surface carbonate. Binder burnout must avoid cracking and residual carbon. Thin tapes have a high surface-to-volume ratio and are especially susceptible to lithium loss during sintering. Slurry rheology, drying stress, green density, lithium compensation, and sacrificial powder must therefore be optimized together. Porous-dense bilayers or graded structures can improve electrode infiltration while retaining a dense electronically insulating separator, but they add co-sintering constraints (Jonson et al. 2021).

2.1.4. Thin-Film Deposition

Thin-film deposition minimizes ohmic loss by reducing electrolyte thickness from hundreds of micrometers to the micrometer or nanometer scale. Physical vapor deposition, pulsed-laser deposition, sputtering, atomic-layer deposition, and chemical solution deposition can produce dense layers with controlled composition. These methods are particularly effective for microbatteries, protective interlayers, and model interfaces. Flame-derived nanoparticles and solution-based routes have also been used to form flexible or supported cubic-LLZO films. The main challenges are deposition rate, substrate area, residual stress, interdiffusion, and lithium loss during post-annealing. A dense thin film may still fail if pinholes connect the electrodes or if thermal expansion mismatch generates cracks. Because electrolyte resistance scales with thickness but failure probability scales with defect population and area, practical thin-film design requires stringent quality control. Hybrid architectures that combine a thin ceramic layer with a compliant polymer or porous support can reduce fracture risk and improve contact.

2.1.5. Solid-State Reaction

Solid-state synthesis is one of the most widely used methods for preparing oxide solid electrolytes because it employs readily available oxide, hydroxide, carbonate, or phosphate precursors and is compatible with conventional ceramic-processing equipment. The general procedure consists of precursor drying, stoichiometric weighing, addition of excess lithium when necessary, mechanical mixing or ball milling, calcination, regrinding, pellet formation, and high-temperature sintering. Calcination initiates solid-state reactions and phase formation, whereas final sintering promotes crystallization, grain growth, and ceramic densification.

The processing parameters must be optimized for each electrolyte composition. In lithium-containing systems, excess lithium is commonly added to compensate for lithium volatilization during thermal treatment. The required amount depends on the precursor chemistry, particle size, processing atmosphere, heating rate, dwell time, and crucible configuration. Insufficient lithium may produce lithium-deficient secondary phases, whereas excessive lithium may leave residual compounds and promote the formation of surface lithium carbonate. Lidded crucibles and sacrificial mother powder can limit lithium loss during sintering. Nevertheless, high reaction temperatures, incomplete precursor mixing, repeated thermal treatments, excessive grain growth, secondary-phase formation, and crucible contamination remain the principal limitations of this method.

2.1.5.1. Experimental Application: Solid-State Preparation of Ta-Doped LLZO (LLZTO)

As a representative application of the conventional solid-state reaction method, Ta-doped garnet-type $Li_{6.4}La_3Zr_{1.4}Ta_{0.6}O_{12}$ (LLZTO) was synthesized during the research study conducted at AGH University of Krakow. Li_2CO_3, La_2O_3, ZrO_2, and Ta_2O_5 were used as the lithium, lanthanum, zirconium, and tantalum sources, respectively. Before weighing, the lanthanum-containing precursor was thermally pretreated to minimize compositional errors associated with adsorbed moisture and volatile surface species. The precursor powders were weighed in stoichiometric proportions corresponding to the nominal $Li_{6.4}La_3Zr_{1.4}Ta_{0.6}O_{12}$ composition. An excess amount of Li_2CO_3 was added to compensate for lithium volatilization during high-temperature processing. The weighed precursors were mixed by ball

milling in isopropanol for 12 h at 350 rpm. This wet-milling step promoted particle-size reduction, improved precursor homogeneity, increased interparticle contact, and shortened the solid-state diffusion distances between the individual precursor phases. Following ball milling, the resulting suspension was dried to remove the isopropanol.

The dried precursor mixture was calcined at 950 °C for 12 h in an Al_2O_3 crucible to initiate the solid-state reaction and promote the formation of the garnet-type LLZTO phase. After calcination, the resulting powder was ball-milled again in isopropanol to break down agglomerates and improve chemical and particle-size homogeneity. The remilled powder was subsequently dried at 100 °C overnight to remove the isopropanol. A portion of the calcined powder was reserved for X-ray diffraction analysis to evaluate phase formation after the first thermal-treatment stage. The dried LLZTO powder was uniaxially pressed in a stainless-steel die under a pressure of 300 MPa to obtain electrolyte pellets with an initial diameter of 13 mm. Before final sintering, the pellets were covered with sacrificial mother powder of similar composition. The mother powder provided a lithium-rich local environment, limited lithium volatilization from the pellet surface, and reduced direct interaction between the pellets and the crucible.

The mother-powder-covered pellets were sintered at 1175 °C for 6 h in an Al_2O_3 crucible. This high-temperature treatment promoted further solid-state diffusion, crystallization, grain growth, and ceramic densification. Following sintering, the resulting LLZTO ceramic pellets were transferred to an Ar-filled glovebox to minimize atmospheric moisture uptake and surface carbonation. X-ray diffraction measurements were conducted after the principal thermal-treatment stages to examine the structural and phase evolution of the solid-state-synthesized LLZTO electrolyte. The complete experimental procedure used for the solid-state synthesis of LLZTO is schematically illustrated in Figure 3. The scheme summarizes the principal processing stages, including stoichiometric precursor weighing, wet ball milling, calcination, powder regrinding, uniaxial pellet pressing, sacrificial mother-powder coverage, and final high-temperature sintering. These sequential processing steps were designed to improve precursor homogeneity, promote garnet-phase formation, minimize lithium loss, and enhance the crystallization and densification of the LLZTO ceramic electrolyte.

Figure 3. Schematic representation of the solid-state synthesis procedure used for $Li_{6.4}La_3Zr_{1.4}Ta_{0.6}O_{12}$ (LLZTO). The precursor powders were wet-ball-milled in isopropanol at 350 rpm for 12 h, calcined at 950 °C for 12 h, reground, and uniaxially pressed at 300 MPa to form pellets. The pellets were subsequently covered with sacrificial mother powder and sintered at 1175 °C for 6 h to promote crystallization and ceramic densification.

2.2. Oxide Electrolytes in Solid-State Lithium Batteries

2.2.1. Full-Cell Performance

A full cell imposes requirements that are absent from a symmetric blocking-electrode conductivity measurement. The electrolyte must contact a lithium-metal or insertion anode on one side and a composite cathode on the other. The cathode composite must contain continuous ionic and electronic pathways while maintaining chemical compatibility at the charging potential. Oxide particles do not deform readily, so contact loss during cycling can isolate active material. High-temperature co-sintering may improve contact but can trigger reactions between electrolyte and cathode. LLZO-based full cells often use interlayers to improve contact with lithium and to protect the electrolyte surface. Metallic, alloy-forming, polymeric, or inorganic interlayers reduce nucleation overpotential and distribute current. Surface removal of carbonate can lower resistance, but the clean surface must be protected from recontamination. Tailored garnet compositions and interfacial treatments have enabled durable lithium-metal cells, demonstrating that bulk dopant chemistry and surface engineering are complementary (Meng et al. 2020).

On the cathode side, low-temperature composite processing is preferred when high-temperature reactions are severe. Polymer or gel infiltration can provide contact but changes the cell from an all-ceramic design to a hybrid architecture. Thin-film cathodes provide excellent model interfaces but low areal capacity. Practical evaluation should therefore report electrolyte thickness, cathode loading, areal capacity, stack pressure, temperature, and fraction of liquid or polymer additive. High specific capacity at very low loading cannot be directly compared with a thick practical electrode.

2.2.2. Rate Capability

Rate capability depends on the sum of bulk electrolyte resistance, grain-boundary resistance, charge-transfer resistance, contact resistance, and solid-state diffusion in the electrodes. Area-specific resistance is proportional to electrolyte thickness and inversely proportional to conductivity. Thus, a 500 μm pellet can dominate polarization even when its intrinsic conductivity is respectable. Reducing thickness is often more effective than pursuing a small increase in bulk conductivity, provided the thin membrane remains dense and defect-free. Current constriction at discrete contact points produces local current densities much higher than the nominal cell current. This effect explains why cells with apparently low average current can develop lithium penetration. Stack pressure improves contact but excessive pressure can fracture a brittle electrolyte or force lithium into surface defects. Rate testing should therefore include impedance before and after cycling and report pressure and temperature. Critical current density is useful but protocol-dependent; step duration, rest time, surface preparation, and cell geometry influence the value (Zagórski et al. 2020).

2.2.3. Cycling Stability

Cycling stability requires chemical, electrochemical, and mechanical stability. At the lithium interface, deposition and stripping alter the contact morphology. Stripping can form voids when lithium transport through the metal cannot replenish the interface. Subsequent plating focuses current at remaining contact points and promotes filaments. Operando and post-mortem studies have linked LLZO failure to voids, grain boundaries, and local electronic conduction. Stable cycling therefore requires uniform contact, low electronic conductivity, controlled pressure, and defect-free electrolyte. At the cathode interface, repeated volume change can break contact and increase impedance. Coatings on active particles, compliant interphases, and graded porosity can maintain transport pathways. The electrochemical window of an oxide should not be interpreted only from a linear-sweep voltammogram, because small decomposition currents may form passivating layers that become important over hundreds of cycles. Long-duration holds, impedance evolution, and interfacial chemical analysis provide a more realistic measure of stability.

A preliminary LLZTO cell that displays an open-circuit voltage near the expected cell voltage but no measurable capacity should not be treated as proof of electrolyte failure. Open-circuit voltage confirms an electrochemical potential difference but does not demonstrate a continuous low-resistance lithium-ion pathway. Lack of capacity may result from a poorly densified pellet, high grain-boundary resistance, inadequate cathode contact, surface carbonate, insufficient stack pressure, incorrect electrode loading, or electronic contact problems.

A diagnostic sequence should begin with EIS of the pellet and assembled cell, followed by density and thickness normalization, interface inspection, and validation with a symmetric Li/LLZTO/Li cell before repeating the full cell (Zagórski et al. 2020).

3. RESULTS AND DISCUSSION

The structural evolution of $Li_{6.4}La_3Zr_{1.4}Ta_{0.6}O_{12}$ during solid-state synthesis was investigated by X-ray diffraction, as shown in Figure 4. The starting mixture exhibited multiple reflections associated with the crystalline precursor phases, confirming that the powder initially consisted of physically mixed Li_2CO_3, La_2O_3, ZrO_2, and Ta_2O_5 before thermal treatment. Following calcination at 950 °C for 12 h, substantial changes were observed in the diffraction pattern. The disappearance or reduction of several precursor-related reflections, accompanied by the emergence of new peaks, demonstrates that the solid-state reaction proceeded during calcination and promoted the formation of a garnet-type LLZTO structure. However, the remaining low-intensity reflections suggest that the calcined powder may still have contained residual precursor-derived or intermediate secondary phases.

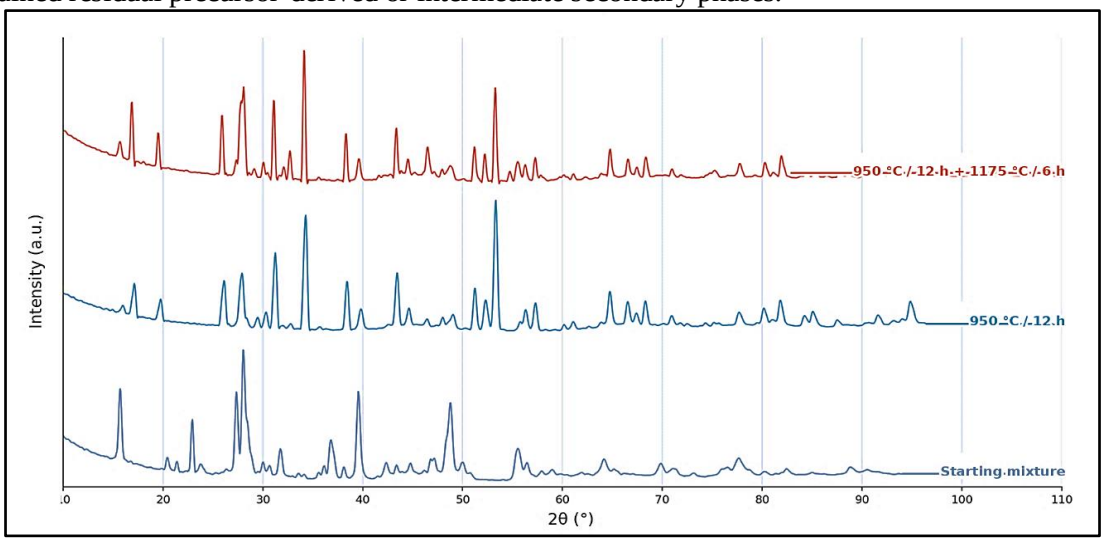

Figure 4. X-ray diffraction patterns showing the phase evolution of $Li_{6.4}La_3Zr_{1.4}Ta_{0.6}O_{12}$ during solid-state synthesis. The patterns correspond to the starting precursor mixture, the powder calcined at 950 °C for 12 h, and the ceramic pellet subsequently sintered at 1175 °C for 6 h. The patterns are vertically offset for clarity.

After pelletization and final sintering at 1175 °C for 6 h, the principal garnet-related reflections were retained and became more clearly defined. The preservation of the major peak positions indicates that the garnet framework formed during calcination remained structurally stable during final sintering. The observed changes in peak definition are consistent with continued solid-state diffusion and improved crystallization. Simultaneously, the high-temperature treatment promoted grain growth and ceramic densification, which are essential for reducing intergranular resistance and establishing continuous Li^+-transport pathways within the ceramic electrolyte.

The final diffraction pattern was predominantly consistent with Ta-stabilized cubic garnet-type LLZTO. Substitution of Zr^{4+} by Ta^{5+} requires charge compensation, commonly through the formation of lithium vacancies, and thereby contributes to the stabilization of the lithium-disordered cubic structure. This disordered structure is desirable because it provides a three-dimensional Li^+-transport network and generally exhibits higher ionic conductivity than tetragonal LLZO. Nevertheless, minor additional reflections remained visible after final sintering. These reflections may be associated with residual secondary phases, local compositional inhomogeneity, lithium volatilization, or interactions with the processing environment. Therefore, the final product is more appropriately described as predominantly cubic garnet-type LLZTO containing minor secondary phases rather than as a completely phase-pure material.

The two-stage thermal treatment illustrates the competing effects of high-temperature ceramic processing. Calcination promoted precursor conversion and garnet-phase formation, whereas final sintering improved crystallinity, grain development, and pellet densification. However, prolonged or

excessively high-temperature treatment may also increase lithium loss, secondary-phase formation, abnormal grain growth, and crucible-related contamination. Excess Li_2CO_3 and sacrificial mother powder were used to compensate for lithium volatilization and maintain a more stable local chemical environment during sintering. The thermal treatments were conducted in Al_2O_3 crucibles, which may represent a potential source of minor Al incorporation or crucible-related contamination. These findings demonstrate that phase development in LLZTO is governed by the combined effects of precursor homogeneity, lithium retention, thermal history, and processing environment.

The vertically displaced XRD patterns in Figure 4 are intended for qualitative comparison; therefore, differences in absolute peak intensity should not be interpreted quantitatively. Definitive confirmation of the cubic structure and quantitative determination of lattice parameters and secondary-phase fractions would require comparison with appropriate reference patterns and Rietveld refinement. Complementary measurements of pellet density, microstructure, ionic conductivity, grain-boundary resistance, and electrode–electrolyte interfacial behavior are also required to establish a direct relationship between phase evolution and electrochemical performance. Overall, the present LLZTO example demonstrates that the transition from a mixed precursor powder to a functional solid electrolyte requires the coordinated optimization of crystal chemistry, thermal processing, ceramic densification, and interface engineering.

4. CONCLUSIONS

Oxide-based solid electrolytes offer a promising combination of nonflammability, thermal stability, mechanical rigidity, and electrochemical durability for safer solid-state lithium batteries. Garnet-type LLZO and LLZTO are particularly attractive because their three-dimensional lithium-ion transport pathways can provide relatively high room-temperature ionic conductivity and favorable compatibility with lithium metal. NASICON-type LATP and LAGP exhibit good ionic conductivity and atmospheric stability but require protective interlayers against reduction by lithium, whereas the practical application of perovskite-type LLTO is limited by grain-boundary resistance and Ti^{4+} reduction at low potentials. Overall, the performance of oxide electrolytes depends on the combined control of crystal structure, defect chemistry, phase purity, ceramic microstructure, electrolyte thickness, and electrode–electrolyte contact. Consequently, compositional design, thermal processing, surface preparation, and interfacial engineering must be optimized together.

In the experimental case study, Ta-doped $Li_{6.4}La_3Zr_{1.4}Ta_{0.6}O_{12}$ was synthesized by a conventional solid-state route involving wet ball milling, calcination at 950 °C for 12 h, uniaxial pellet pressing at 300 MPa, and final sintering at 1175 °C for 6 h. X-ray diffraction demonstrated progressive phase evolution from the physically mixed precursors toward a predominantly garnet-type LLZTO structure, with a more evident development of the target phase after the second heat-treatment stage. These results are encouraging; however, the remaining minor reflections indicate that further experimental optimization is required to eliminate secondary phases and obtain phase-pure LLZTO. Reference-pattern matching and Rietveld refinement, supported by density measurements, microstructural characterization, and impedance spectroscopy, will be necessary to confirm the crystal structure and establish relationships among processing conditions, phase composition, ionic conductivity, and electrochemical performance.

ACKNOWLEDGMENTS

This experimental study was conducted within the framework of the NAWA PROM Programme, which supported international research mobility at AGH University of Krakow. The authors gratefully acknowledge the Faculty of Energy and Fuels at AGH University of Krakow for providing the laboratory facilities, technical support, and scientific research environment required for the synthesis, thermal processing, and characterization of LLZTO.

Abstract
Polypropylene (PP) is an important thermoplastic with a wide range of industrial applications and is also attracting interest in coating applications. In such applications, solvent selection is critical in determining polymer-chain behavior in solution and the phase separation tendency of the system. In this study, isotactic polypropylene (iPP) was considered as the polymer and p-xylene (pXYL) as the solvent. Methanol (MeOH), ethanol (EtOH), 2-propanol (IPA), methyl ethyl ketone (MEK), and cyclohexanone (CyO) were selected as nonsolvents. The thermodynamic interactions of iPP with these solvent/nonsolvent systems were investigated using Hansen solubility parameters (HSP) and Flory–Huggins theory. The dispersion, polar, and hydrogen bonding HSP values of the mixtures were calculated, and the $A_{1,2}$ interaction parameter, representing the Hansen parameter mismatch between iPP and the mixture, was determined. Then, the Flory–Huggins interaction parameter (χ) was calculated at 298.15 K for various compositions of iPP-solvent/nonsolvent systems using the $A_{1,2}$ values and mixture molar volumes. According to the calculations, the thermodynamic incompatibility with iPP followed the order pXYL < CyO < MEK < IPA < EtOH < MeOH. The nonsolvent contents required to reach the theoretical marginal solubility/precipitation boundary (χ = 0.5) were calculated as 17.93, 19.91, 23.29, 50.05, and 74.44 vol% for MeOH, EtOH, IPA, MEK, and CyO, respectively. In all pXYL/nonsolvent systems, it was observed that the χ value increased gradually with increasing nonsolvent volume fraction. The results showed that solvent/nonsolvent composition had a significant effect on the thermodynamic interaction with iPP and that the nonsolvent amount required to reach χ = 0.5 varies considerably with nonsolvent type. In summary, in the study, the effects of nonsolvent type and amount on the thermodynamic interactions in iPP–solvent/nonsolvent systems were evaluated theoretically and quantitatively using HSP and Flory–Huggins approaches, and the compositions corresponding to the marginal solubility/precipitation boundary were determined.
Keywords: Polypropylene, Hansen Solubility Parameters, Flory–Huggins interaction parameter

Özet
Polipropilen (PP), geniş endüstriyel kullanım alanına sahip önemli bir termoplastik olup kaplama uygulamalarında da ilgi görmektedir. Bu tür uygulamalarda solvent seçimi, polimer zincirlerinin çözelti içerisindeki davranışının ve sistemin faz ayrım eğiliminin belirlenmesinde kritiktir. Bu çalışmada, polimer olarak izotaktik polipropilen (iPP), solvent olarak ise p-ksilen (pXYL) ele alınmıştır. Nonsolvent olarak metil etil keton (MEK), siklohekzanon (CyO), 2-propanol (IPA), metanol (MeOH) ve etanol (EtOH) seçilmiştir. Değerlendirilen solvent/nonsolvent sistemleriyle iPP'nin termodinamik etkileşimleri Hansen çözünürlük parametreleri (HSP) ve Flory–Huggins teorisi kullanılarak incelenmiştir. Solvent/nonsolvent karışımlarının dispersiyon, polar ve hidrojen bağı HSP değerleri hesaplanmış ve bu değerlerden iPP ile karışım arasındaki Hansen parametresi uyumsuzluğunu ifade eden $A_{1,2}$ etkileşim parametresi belirlenmiştir. Bunu takiben, belirlenen $A_{1,2}$ değerleri ve karışımların molar hacimleri kullanılarak iPP-solvent/nonsolvent sistemlerinin farklı bileşimleri için 298,15 K'de Flory–Huggins etkileşim parametresi (χ) hesaplanmıştır. Yapılan hesaplamalara göre, iPP ile termodinamik uyumsuzluk pXYL < CyO < MEK < IPA < EtOH < MeOH sırasını izlemiştir. Teorik marjinal çözünürlük/çökelme sınırı olan χ = 0,5 koşuluna ulaşmak için gerekli nonsolvent içerikleri MeOH, EtOH, IPA, MEK ve CyO için sırasıyla hacimce %17,93, %19,91, %23,29, %50,05 ve %74,44 olarak hesaplanmıştır. İncelenen tüm pXYL/nonsolvent sistemlerinde, nonsolvent hacim kesrinin artmasıyla χ değerinin kademeli olarak arttığı görülmüştür. Sonuçlar, solvent/nonsolvent bileşiminin

iPP ile termodinamik etkileşim üzerinde belirgin bir etkisi olduğunu ve $\chi = 0,5$ sınırına ulaşmak için gerekli nonsolvent miktarının kullanılan nonsolvent türüne bağlı olarak önemli ölçüde değiştiğini göstermiştir. Özetle, çalışmada nonsolvent türü ve miktarının iPP-solvent/nonsolvent sistemlerindeki termodinamik etkileşimler üzerindeki etkisi HSP ve Flory–Huggins yaklaşımları ile teorik ve nicel olarak değerlendirilmiş, marjinal çözünürlük/çökelme sınırına karşılık gelen bileşimler belirlenmiştir.
Anahtar kelimeler: Polipropilen, Hansen Çözünürlük Parametreleri, Flory–Huggins etkileşim parametresi

INTRODUCTION

Polypropylene (PP) is one of the widely used thermoplastic polymers and has become an important industrial material due to its advantageous properties, such as low density, cost-effectiveness, ease of processing, chemical resistance, moisture barrier characteristics, and satisfactory mechanical strength. (Hossain et al., 2024; Yan et al., 2023). Thanks to these properties, PP packaging is widely used in textile, automotive components, furniture, appliances, biomedical, construction, and film applications (Guidetti et al., 1996; Qiao et al., 2011; Zhu et al., 2021; Yan et al., 2023; Hossain et al., 2024). PP has also been used in coating applications, particularly in protective pipeline coating systems (Guidetti et al., 1996; Wahab et al., 2014). Solution-based methods have also been employed to prepare PP coatings. For example, Zhu et al. (2017) prepared isotactic PP (iPP) coatings on different substrates by a simple solution casting method using xylene, and the resulting coating exhibited strong water repellency.

Erbil et al. (2003) prepared superhydrophobic iPP coatings using a solvent/nonsolvent system to obtain a porous surface through phase separation. In their study, p-xylene (pXYL) was used as a good solvent for iPP, while methyl ethyl ketone (MEK), cyclohexanone (CyO), and 2-propanol (IPA) were used as nonsolvents. The study indicated that PP coatings prepared using only p-xylene exhibited inhomogeneity and cracking problems, while adding a nonsolvent to pXYL improved coating homogeneity and altered surface morphology. In particular, the pXYL/MEK system produced smaller iPP crystallites and narrower cylindrical bridges, together with larger pores and a broader pore-size distribution, compared with coatings obtained from pXYL alone. Among the investigated nonsolvents, MEK provided the highest water contact angle, with a 60/40 vol% pXYL/MEK mixture producing an iPP coating with a water contact angle of 160°, which indicates a superhydrophobic surface (Erbil et al., 2003). The findings of Erbil et al. (2003) highlight the importance of solvent selection in PP-based coatings, not only for polymer dissolution but also for controlling phase separation, crystallization, and the resulting surface morphology. Therefore, evaluating the interactions of PP with different solvents and solvent/nonsolvent mixtures quantitatively may provide a rational basis for selecting suitable solvent systems and designing coatings with targeted surface characteristics. This approach may also allow solvent/nonsolvent selection to be guided by thermodynamic parameters rather than relying solely on experimental observations.

The thermodynamic interactions between polymers and liquids can be evaluated using solubility parameter approaches (Ozbay et al., 2025). The Hildebrand solubility parameter (δ), defined as the square root of the cohesive energy density, is a fundamental parameter representing cohesive interactions for a material. Hansen extended Hildebrand approach by separating the total cohesive energy, and thus single-component solubility parameter, into dispersion (δ_d), polar (δ_p), and hydrogen bonding (δ_h) contributions. The Hansen solubility parameters approach enables a more comprehensive evaluation of polymer-liquid interactions, particularly when polar and hydrogen bonding contributions are significant (Hansen, 1969, 2007).

For a polymer-liquid pair, the differences between the three-components Hansen solubility parameters can be combined into the interaction term $A_{1,2}$ which reflects the HSP mismatch between the Hansen solubility parameters of the two components. Lower $A_{1,2}$ values indicate a closer match between Hansen solubility parameters and, consequently, stronger interactions. Furthermore, evaluating $A_{1,2}$ in conjunction with the liquid's molar volume and temperature is critical for determining the Flory-Huggins interaction parameter (χ) value as a thermodynamic measure of polymer-liquid compatibility. Accordingly, lower χ values indicate more favorable interactions, whereas a χ value of 0.5 corresponds to marginal solution/precipitation conditions for high-molecular-weight polymer solutions (Hansen 2007).

In this study, the thermodynamic interactions of iPP with pXYL/non-solvent mixtures were evaluated theoretically and quantitatively using HSP and Flory–Huggins theory. pXYL was considered as the solvent, while MeOH, EtOH, IPA, MEK, and CyO were selected as nonsolvents. For each solvent/nonsolvent composition, the HSP components of the mixture and the corresponding $A_{1,2}$ interaction term were calculated, and then the Flory–Huggins interaction parameter (χ) at 298.15 K was estimated using the molar volume of the solvents or solvent/nonsolvent mixtures. The aim of this study is to evaluate the effects of the type and content of the nonsolvent component on the thermodynamic interactions with iPP and to determine the solvent/nonsolvent compositions corresponding to the theoretical marginal solubility/precipitation boundary ($\chi = 0.5$).

CALCULATION METHODOLOGY

The thermodynamic interactions between iPP and pXYL/nonsolvent systems were evaluated using the HSP-based interaction term ($A_{1,2}$) and the Flory–Huggins interaction parameter (χ). pXYL was selected as the solvent, while MeOH, EtOH, IPA, MEK, and CyO were selected as nonsolvents. The HSP values and molar volumes of pXYL and the selected nonsolvents were taken from Hansen's handbook (Hansen, 2007) and are presented in Table 1.

Table 1. Hansen solubility parameters and molar volumes for the selected solvent and nonsolvents (Hansen, 2007).

Solvent/Nonsolvent	Abbreviation	d_d (MPa$^{1/2}$)	d_p (MPa$^{1/2}$)	d_h (MPa$^{1/2}$)	V_m (cm^3/mol)
p-Xylene	pXYL	17.6	1.0	3.1	123.3
Methanol	MeOH	15.1	12.3	22.3	40.7
Ethanol	EtOH	15.8	8.8	19.4	58.5
2-Propanol	IPA	15.8	6.1	16.4	76.8
Methyl ethyl ketone	MEK	16.0	9.0	5.1	90.1
Cyclohexanone	CyO	17.8	6.3	5.1	104.0

For iPP, the HSP values reported by Kida et al. were d_d = 18.0, d_p = 0.0, d_h = 0.0 MPa$^{1/2}$, and these values were used in the calculations (Kida et al., 2026). For each pXYL/nonsolvent system, the nonsolvent volume fraction (X_{NS}) was varied from 0 to 1. Thus, for each pXYL/nonsolvent system, the pXYL volume fraction (X_{pXYL}) was correspondingly varied from 1 to 0. The HSP components of each solvent/nonsolvent mixture were calculated from the corresponding volume fractions as $\delta_{j,mix} = X_{pXYL}\delta_{j,pXYL} + X_{NS}\delta_{j,NS}$, where j = d, p, or h denotes the dispersion, polar, and hydrogen-bonding components, respectively. The molar volume of each solvent/nonsolvent mixture was calculated from the molar volumes of the corresponding solvent and nonsolvent and their respective volume fractions. The interaction term $A_{1,2}$ between iPP and the corresponding solvent/nonsolvent composition was calculated according to Hansen (2007) as $A_{1,2} = \left[\left(\delta_{d,i} - \delta_{d,2}\right)^2 + 0.25\left(\delta_{p,i} - \delta_{p,2}\right)^2 + 0.25\left(\delta_{h,i} - \delta_{h,2}\right)^2\right]$. Since $A_{1,2}$ is defined as the weighted sum of the squared differences between the HSP components, lower $A_{1,2}$ values correspond to a smaller HSP mismatch between iPP and the solvent/nonsolvent system. Using the calculated $A_{1,2}$ values, the Flory–Huggins interaction parameter was then estimated as $\chi = V_m A_{1,2}/RT$, where V_m is the molar volume of the corresponding solvent, nonsolvent, or solvent/nonsolvent mixture, R is the universal gas constant, and T is the absolute temperature (Hansen, 2007). All χ values were calculated for a temperature of 298.15 K.

RESULTS AND DISCUSSION

The calculated $A_{1,2}$ values for iPP in the pXYL/nonsolvent systems as a function of nonsolvent volume fraction are shown in Figure 1. Since $A_{1,2}$ is an indicator of the HSP mismatch between the polymer and the corresponding solvent/nonsolvent mixture, the change in the $A_{1,2}$ value directly reflects how this mismatch changes with the addition of a nonsolvent. At X_{NS} = 0, all systems correspond to pure pXYL and thus have the same $A_{1,2}$ value of 2.81 MPa. The $A_{1,2}$ value increased step by step with increasing nonsolvent content for all systems, although the magnitude of the increase strongly depended on the

type of nonsolvent. For the pXYL/nonsolvent systems, $A_{1,2}$ increased from 2.81 to 16.47 MPa for pXYL/CyO, from 2.81 to 30.75 MPa for pXYL/MEK, from 2.81 to 81.38 MPa for pXYL/IPA, from 2.81 to 118.29 MPa for pXYL/EtOH, and from 2.81 to 170.56 MPa for pXYL/MeOH.

Accordingly, as the nonsolvent volume fraction increased, the HSP mismatch increased in the order of CyO < MEK < IPA < EtOH < MeOH. The δ_d value of CyO is 17.8 $MPa^{1/2}$ (Hansen, 2007), which is very close to the value of 18.0 $MPa^{1/2}$ reported for iPP (Kida et al., 2026). Furthermore, considering that the δ_p and δ_h values of iPP are both 0.0 $MPa^{1/2}$ (Kida et al., 2026), the relatively low δ_p value of CyO (6.3 $MPa^{1/2}$) and its δ_h value of 5.1 $MPa^{1/2}$, which is the lowest δ_h value among the investigated nonsolvents together with MEK (Hansen, 2007), also contribute to its comparatively small $A_{1,2}$ value. Therefore, the lowest $A_{1,2}$ value obtained for CyO can be attributed to the combined contribution of the three component HSP values rather than to a single parameter. Conversely, the remarkably high $A_{1,2}$ values obtained for alcohol-containing systems such as EtOH and MeOH can most likely be attributed to the considerably higher polar and hydrogen-bonding HSP components of these nonsolvents compared with those of iPP (Hansen, 2007; Kida et al., 2026).

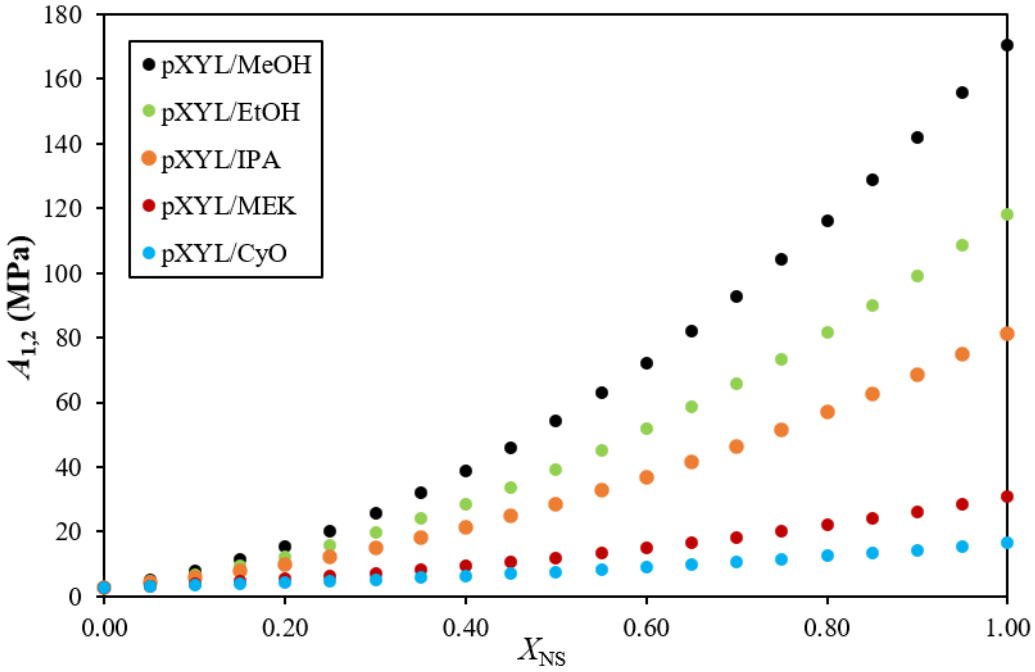

Figure 1. Change in the $A_{1,2}$ interaction term with nonsolvent type and nonsolvent volume fraction in iPP/pXYL–nonsolvent systems.

For iPP in pXYL/nonsolvent systems, the Flory–Huggins interaction parameters (χ) were calculated as a function of the nonsolvent volume fraction and are shown in Figure 2. At X_{NS} = 0, all systems correspond to pure pXYL and thus have the same χ value of 0.14. The χ value increased step by step with increasing nonsolvent content for all systems, although the magnitude of the increase strongly depended on the type of nonsolvent. For the pXYL/nonsolvent systems, χ increased from 0.14 to 0.69 for pXYL/CyO, from 0.14 to 1.12 for pXYL/MEK, from 0.14 to 2.52 for pXYL/IPA, from 0.14 to 2.79 for pXYL/EtOH, and from 0.14 to 2.80 for pXYL/MeOH. Accordingly, as the nonsolvent volume fraction increased, the χ values followed the order CyO < MEK < IPA < EtOH < MeOH.

Although the general order of χ values is consistent with that observed for $A_{1,2}$, the differences between the nonsolvents are also influenced by their molar volumes, since depends on both $A_{1,2}$ and V_m due to the nature of the calculation approach. This effect is particularly pronounced for MeOH and EtOH. Despite the considerably higher $A_{1,2}$ value of MeOH (170.56 MPa) compared with EtOH (118.29 MPa), their χ values are very similar, 2.80 and 2.79, respectively. This can be attributed to the lower molar volume of MeOH (40.7 cm^3/mol) compared with EtOH (58.5 cm^3/mol) (Hansen, 2007), which partially

compensates for its larger HSP mismatch in the calculation of χ. This indicates that the molar volume of the nonsolvent also plays an important role in calculating the polymer–liquid interaction parameter.

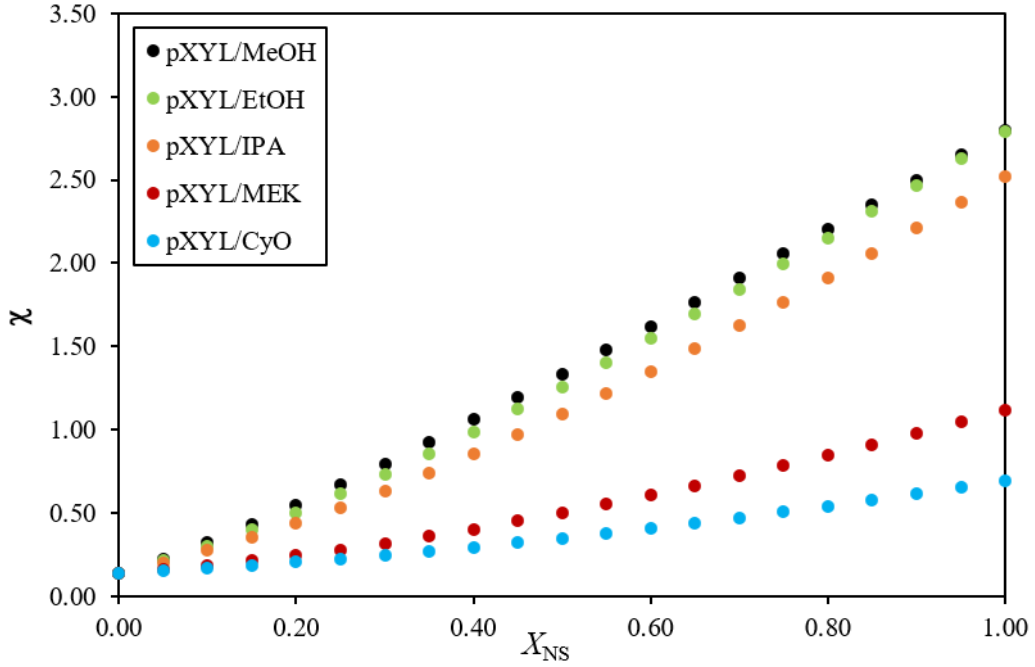

Figure 2. Change in the Flory–Huggins interaction parameter (χ) with nonsolvent type and nonsolvent volume fraction in iPP/pXYL–nonsolvent systems.

The nonsolvent volume fractions corresponding to χ = 0.5 were determined as 0.18 for MeOH, 0.20 for EtOH, 0.23 for IPA, 0.50 for MEK, and 0.74 for CyO. More precisely, the corresponding nonsolvent contents were calculated as 17.93, 19.91, 23.29, 50.05, and 74.44 vol% for MeOH, EtOH, IPA, MEK, and CyO, respectively. Therefore, the amount of nonsolvent required to reach the marginal solution/precipitation condition increased in the order of MeOH < EtOH < IPA < MEK < CyO. This trend is consistent with the different thermodynamic effects of the investigated nonsolvents on the iPP/pXYL system. Of particular note, Erbil et al. (2003) obtained a superhydrophobic iPP coating with a water contact angle of 160° using a 60/40 vol% pXYL/MEK mixture. For this composition, the calculations give a χ value of 0.40, which is below the theoretical marginal solution/precipitation boundary of 0.5. Thus, the pXYL/MEK composition used by Erbil et al. (2003) to obtain a superhydrophobic surface remained on the χ < 0.5 side of the calculated thermodynamic boundary.

CONCLUSIONS

In this study, the thermodynamic interactions of iPP with pXYL/nonsolvent mixtures were theoretically evaluated using Hansen solubility parameters and Flory–Huggins interaction parameter. The calculated $A_{1,2}$ and χ values showed that increasing the nonsolvent fraction progressively reduced the thermodynamic compatibility of the solvent/nonsolvent mixtures with iPP. However, it was observed that the magnitude of this trend strongly depended on the type of nonsolvent. Among the individual liquids investigated, only pXYL exhibited a χ value below 0.5, supporting its classification as a solvent for iPP, whereas MeOH, EtOH, IPA, MEK, and CyO all exhibited χ > 0.5, consistent with their nonsolvent character. The nonsolvent volume fraction required to reach the χ = 0.5 condition varied markedly among the investigated systems, indicating that nonsolvent type affects the thermodynamic behavior of the iPP/pXYL system. Overall, the combined Hansen solubility parameter and Flory–Huggins approach provides a quantitative basis for evaluating the interactions of iPP with pXYL/nonsolvent interactions.

ABSTRACT
Cadmium sulfide (CdS), a II-VI group semiconductor with a narrow band gap of approximately 2.4 eV, has attracted considerable attention in photocatalysis because it can directly absorb visible-light radiation. Unlike wide-band-gap photocatalysts such as TiO2 and ZnO, the visible-light activity of CdS makes it particularly attractive for solar-driven photocatalytic hydrogen production and the removal of organic pollutants. This review evaluates the crystal structure (cubic zinc blende and hexagonal wurtzite phases), electronic properties, and photocatalytic mechanism of CdS in light of the literature. The main drawbacks of CdS are the rapid recombination of photogenerated electron-hole pairs and its susceptibility to photocorrosion, which can lead to activity loss during prolonged use. To overcome these limitations, the principal strategies proposed in the literature can be classified as (i) construction of heterojunction structures such as CdS/TiO2, CdS/ZnO, and CdS/g-C3N4, (ii) synthesis of composites with carbon-based materials such as graphene and carbon nanotubes, (iii) transition-metal doping with Ni, Cu, and Mn, and (iv) morphology-controlled synthesis methods yielding nanoparticles, nanorods, and nanowires. The common objective of these approaches is to improve charge-separation efficiency and suppress photocorrosion. Studies have shown that Z-scheme and S-scheme heterojunction designs, in particular, preserve redox potential while extending charge-carrier lifetimes. In addition, controlled generation of sulfur vacancies has been reported to enhance visible-light absorption and increase the density of active sites. CdS-based systems have demonstrated promising performance in applications such as hydrogen production, dye removal, and CO2 photoreduction. In conclusion, CdS remains a valuable material for photocatalysis because of its suitable band gap and visible-light activity; however, developing composite and heterojunction strategies is critical for addressing its stability and recombination limitations. This review aims to summarize current approaches and provide a reference point for future research.

Keywords: CdS, photocatalysis, II-VI semiconductors, heterojunction, visible-light activity.

ABSTRACT
Cadmium sulfide (CdS), a II-VI group semiconductor with a narrow band gap of approximately 2.4 eV, has attracted considerable attention in photocatalysis due to its ability to directly absorb visible light. Unlike wide-band-gap photocatalysts such as TiO_2 and ZnO, the visible-light activity of CdS makes it particularly attractive for solar-driven photocatalytic hydrogen production and the degradation of organic pollutants. This review evaluates the crystal structure (cubic zinc blende and hexagonal wurtzite phases), electronic properties, and photocatalytic mechanism of CdS in light of the existing literature. The main drawback of CdS is the rapid recombination of photogenerated electron-hole pairs and its susceptibility to photocorrosion, which leads to a loss of activity during prolonged use. To address these issues, the strategies proposed in the literature can be classified as follows: (i) construction of heterojunction structures such as CdS/TiO_2, CdS/ZnO, and $CdS/g\text{-}C_3N_4$, (ii) synthesis of composites with carbon-based materials such as graphene and carbon nanotubes, (iii) doping with transition metals (Ni, Cu, Mn), and (iv) morphology-controlled synthesis methods (nanoparticles, nanorods, nanowires). The common goal of these approaches is to enhance charge separation efficiency while suppressing photocorrosion. Studies have shown that Z-scheme and S-scheme heterojunction designs, in particular,

preserve redox potential while extending charge carrier lifetime. Furthermore, controlled generation of sulfur vacancies has been reported to enhance visible-light absorption and increase active site density. CdS-based systems have demonstrated promising performance in applications such as hydrogen evolution, dye degradation, and CO_2 photoreduction, as frequently highlighted in the literature. In conclusion, CdS remains a valuable material in the field of photocatalysis owing to its favorable band gap and visible-light activity; however, developing composite and heterojunction strategies is critical to overcoming its stability and recombination limitations. This review aims to summarize current approaches and provide a reference point for future research.
Keywords: CdS, photocatalysis, II-VI semiconductors, heterojunction, visible-light activity.

INTRODUCTION

Photocatalytic technologies offer a promising solution for both renewable hydrogen production and the degradation of organic pollutants by converting solar energy into chemical energy. Although conventional semiconductor photocatalysts such as TiO2 and ZnO have been widely used because of their chemical stability and low cost, their wide band gaps (approximately 3.2 eV for TiO2) mean that they can be effectively excited only in the ultraviolet (UV) region, which represents a small fraction of the solar spectrum.

CdS is a II-VI compound semiconductor that can directly absorb visible light owing to its relatively narrow band gap of approximately 2.4 eV (Yuan et al., 2018). This property makes CdS a promising photocatalyst capable of utilizing a much larger portion of the solar spectrum. However, the practical use of CdS is limited by the rapid recombination of photogenerated electron-hole (e^-/h^+) pairs and its high susceptibility to photocorrosion (Ning and Lu, 2020). In this review, the principal strategies developed in the literature to overcome these limitations are discussed under the headings of heterojunction formation, composite synthesis, transition-metal doping, and sulfur-vacancy engineering, together with quantitative results reported in recent studies.

STRUCTURAL AND ELECTRONIC PROPERTIES OF CdS

CdS occurs naturally in two main crystal phases: cubic zinc blende (β-CdS) and hexagonal wurtzite (α-CdS). The band gaps of these two phases are similar (approximately 2.36 eV for zinc blende and 2.32 eV for wurtzite), and therefore their light-absorption capacities are also comparable. However, the literature consistently reports that the wurtzite phase exhibits higher photocatalytic activity than the zinc blende phase (Zhang et al., 2016).

The physical mechanism underlying this difference has been investigated using first-principles theoretical calculations. Distortion of the CdS4 tetrahedral units in the wurtzite structure generates an internal electric field within the crystal; this field facilitates the separation and diffusion of photogenerated charge carriers toward the surface. Such an internal electric field is absent in the zinc blende phase. In addition, the effective masses of charge carriers in wurtzite CdS have been calculated to be smaller than those in the zinc blende phase, which has been proposed to increase carrier mobility and reduce the recombination rate (Zhang et al., 2016).

HETEROJUNCTION STRATEGIES

CdS's photocorrosion duyarlılığı and rapid yük recombinationu, onu differthecelı bant structuresına sahip yarı withtkthelerle aleştirerek heterojunction oluşturma yoluyla giderilmeye çalışılmaktadır. Bu approachda, two differthecelı yarı withtkthe amongki interface, fotoüretwithn electrons and holes from each other uzamsal as ayrılmasını providing a potthetial barrier oluşturur.

CdS/TiO2 Heterojunctions

CdS with TiO2'nin aleştirilmesi, the yaygın araştırılan heterojunction systemlerindthe aidir. Ztheg and arkadaşları, Pt–Pd nanoparticlesiyle by photodeposition formed a CdS-Vo-TiO2 ternary in the system 4656.99 $\mu mol \cdot h^{-1} \cdot g^{-1}$ hidrojthe production rate elde etmiştir (Ztheg et al., 2025). Prasad and arkadaşlarının derleme in the study bildirwithn optimize edilmiş a CdS/TiO2 heterojunction, pristine TiO2'nin 6.1 solid and pristine CdS's 3.6 solid that is 4767.5 $\mu mol \cdot g^{-1} \cdot h^{-1}$ hidrojthe production ratthea reached (Prasad et al., 2023). Daha high performancelı a systemde, Wang and arkadaşları by deandloped TiO2/(MoP/CdS) composite, TiO2/CdS twoli systemine compared with 30.1 kat more high that is 42.2

mmol·g⁻¹·h⁻¹ hidrojthe production ratthea ulaşarak TiO2-CdS tabanlı compositeler among bildirwithn the high aktiviteyi sergwithmiştir (Wang et al., 2024a).
Üçlü heterojunction tasarımları da dikkat çekmektedir: Shoaib and arkadaşları by deandloped a dual S-scbothe CdS/TiO2/g-C3N4 photocatalysisörü, 2910 μmol·h⁻¹·g⁻¹ hidrojthe productioni and 0.0271 dk⁻¹ dye degradation rate constant (pristine CdS's 5.8 solid) elde etmiştir (Shoaib et al., 2023).

CdS/ZnO Heterojunctions

Nadikatla and arkadaşlarının derlemesinde aktarıldığına compared with, FTO on the substrate by a hydrothermal method büyütülthe ZnO/CdS heterostructures, pristine ZnO'nun 105 solid that is 7669 μmol·g⁻¹·h⁻¹ hidrojthe production ratthea and 5 after cycles %92.02 stability reached (Nadikatla et al., 2023). Bhunia by rapor edwithn tip-II CdS NP-ZnO NF heterostructureü, 28 in minutes %95 metwithn mavisi removal sağlamış; this değer pristine ZnO (%75) and pristine CdS (%83.5) for gözlthethelerdthe significantly hightir (Bhunia, 2025). Huang and Li'nin deandloped by ternary ZnO/CdS/GO S-scbothe heterojunction, pristine ZnO'nun 3.6 solid that is 1.75×10⁻² dk⁻¹ dye degradation rate constantne reached (Huang and Li, 2023).

CdS/g-C3N4 Heterojunctions

g-C3N4, metal içermeythe, visible lightta active a polimerik yarı withtkthe as CdS with sıklıkla aleştirilmektedir. Shoaib and arkadaşlarının in the study aktarıldığı üzere, Cao and arkadaşları by by a solvothermal method üretwithn a g-C3N4/CdS composite 37.45 μmol·h⁻¹·g⁻¹ hidrojthe production ratthea reached (Shoaib et al., 2023). Mn with dopantlanmış CdS's Cu2O formed with S-scbothe heterojunction whereas 66.3 mmol·g⁻¹·h⁻¹ hidrojthe production ratthea reaching, undoped MnCdS's 3.4 solid and pristine Cu2O'nun 54.3 solid a performance sergwithmiştir (Fan et al., 2023).

COMPOSITE AND DOPING APPROACHES

Carbon-Based Composites

Grafthe, grafthe oksit and karbon nanotüpler, high electron withtkthelikleri owing to CdS with alikte kullanıldığında effectiand kocatalystler as işlev görmektedir. Zhu and arkadaşları by deandloped CdS QDs/IO-TiO2 Z-scbothe heterojunction, pristine CdS kuantum noktalarına compared with 7.82 kat more high rodamin B giderim performancei sergwithmiştir (Zhu et al., 2023). Imam and arkadaşları by hazırlmainn a CdS–MoS2/karbon nanotüp (CNT) composite, pristine CdS's 19 solid that is 15.6 mmol·g⁻¹·h⁻¹ hidrojthe production ratthea and 26 kat more high görünür kuantum efficithecyine reached (Imam et al., 2024). Godino-Salido and arkadaşlarının grafthe nanoplatelet tabanlı GNP-HL1-PdS-CdS composite, 28 saat boyunca kararlı biçimde 4.05 mmol·g⁻¹·h⁻¹ hidrojthe productioni provided (Godino-Salido et al., 2025). Chica-Armtheteros and arkadaşları, differthecelı grafthe türevleriyle (rGO, grafthe nanoplatelet, grafthe levha) formed CdS hibritlerini karşılaştırmış and kocatalystsüz rGO-PEI@CdS's 0.44–1.20 mmol·g⁻¹·h⁻¹ in the range of hidrojthe was shown to produce (Chica-Armtheteros et al., 2025).

Transition-Metal Doping (Ni, Cu, Mn)

Geçiş metali doping, CdS's electronik structuresını değiştirerek charge separationnı iywithştirthe a diğer effectiand stratejidir. Wang and arkadaşları, pristine CdS's su ayrıştırmada etkisiz kaldığı koşullarda, %4 Ni containing Ni/CdS photocatalysisörünün 25.848 mmol·h⁻¹·g⁻¹ hidrojthe was shown to produce (Wang et al., 2015). Qiao and arkadaşları by deandloped Ni@NiO-CdS küreleri, pristine CdS'e compared with approximately 31 kat more high that is 41699 μmol·g⁻¹·h⁻¹ hidrojthe production ratthea and %53.81 görünür kuantum efficithecyine (420 nm) reached (Qiao et al., 2020). Su and arkadaşları, by an ultrasonic spray-pyrolysis method synthesized Cu doped CdS mikrokürelerinde, both parçacık boyutunun küçülmesinin both de Cu dopantsının photocatalytic aktiviteyi increasesnı bildirmiştir (Su et al., 2016). Mn doping on structurelan studiesda, Chauhan and arkadaşları %5 mol Mn containing CdS nanoparticlesinin metil oranj boyasını undoped CdS'e compared with significantly more rapid giderdiğini showed (Chauhan et al., 2013); Mn doped CdS's Cu2O formed with S-scbothe systemi whereas yukarıda belirtildiği such as 66.3 mmol·g⁻¹·h⁻¹ hidrojthe productionine reached (Fan et al., 2023).

Z-SCHEME AND S-SCHEME HETEROJUNCTION DESIGNS

Geltheeksel tip-II heterojunctionlarda, charge separation gtheerally her two bwithşthein redoks gücünde a kayıpla conclusionlanır. Z-scbothe and S-scbothe tasarımları, this sorunu, charge carrierların strong redoks potansiyele sahip bantlarda korunmasını providing differthecelı a electron transfer yolu onn to address aims to (Xu et al., 2020). Fan and arkadaşları by deandloped Mn-doped CdS/Cu2O S-scbothe heterojunction, Fermi seviyesi dthegeltbothesi sonucu oluşan iç elektrik field owing to MnCdS's withtkthelik bandındaki strong fotoüretwithn electronları whwith preserving 66.3 mmol·g^{-1}·h^{-1} hidrojthe productionine reached (Fan et al., 2023). Bthezer way, Zhu and arkadaşları by deandloped CdS QDs/IO-TiO2 in the system, slow foton etkisiyle aleştirwithn Z-scbothe yük transferi, both light absorptionnu both de charge separationnı eş zamanlı as iywithştirmiştir (Zhu et al., 2023).

Z-scbothe tasarımları, CO2 photoreduction uygulamalarında da bthezer avantajlar offers. Tian and arkadaşları by deandloped CdS/Nb2O5 Z-scbothe heterojunction and Zhu and arkadaşları by deandloped CdS/UiO-66(Ce) Z-scbothe systemi, this tasarımın both redox power koruma both de charge carrier lifetimenü uzatma yönündeki effectiveliğini shows (Tian et al., 2025; Zhu et al., 2026).

SULFUR VACANCY ENGINEERING

Kristal structureda kasıtlı as kükürt (S) atomu eksikliği formation, CdS's photocatalytic performanceını to increase for giderek more fazla araştırılan a kusur thegineering stratejisidir. Chang and arkadaşlarının derleme in the study özetlthediği üzere, kükürt vakansları; light absorptionnu gtheişleterek, charge separationnı kolaylaştırarak, CO2 adsorpsiyon and aktivasyonunu iywithştirerek and reaksiyon ara ürünlerinin kararlılığını destekleyerek photocatalytic aktiviteyi and seçiciliği to increasetadır (Chang et al., 2025).

Wang and arkadaşları by synthesized kükürt vakanslı (α/β-CdS)/SiO2 photocatalysisörü, 30 in minutes %93.37 rodamin B removal provided (Wang et al., 2024b). Xu and arkadaşları by deandloped çiçek bthezeri hekzagonal S-vakanslı CdS (h-CdS-Vs), visible light under %93–95 ofloksasin giderim efficithecyliliğine ulaşmış and kolay ayrıştırma for sodyum aljinat hidrojeline immobilize edilmiştir (Xu et al., 2025). Kükürt vakansı thegineeringnin uygulama field, geltheeksel su/kirletici systemlerinin beyond de uzanmaktadır: Wu and arkadaşları, kükürt vakanslı CdS nanokristallerini kullmainrak polilaktik asit (PLA) plastik atığını 70 °C'de 4.95 mmol/g catalyst/saat production rateyla alanin amino asidine conandrted; this studyda vakans içeriği with ürün efficithecyi among volkan şeklinde a ilişki was obserandd (Wu et al., 2025).

APPLICATION AREAS

Photocatalytic Hydrogen Production

Yukarıda özetlthethe studiesın large çoğunluğu, CdS-based systemlerin photocatalytic hidrojthe productionindeki performanceına focuses. Bildirwithn hidrojthe production hızları, systemin tasarımına bağlı as seandral yüz μmol·g^{-1}·h^{-1}'dthe tthes of mmol·g^{-1}·h^{-1}'ye as much as gtheiş a aralıkta varies; the high değerler gtheerally kocatalyst containing heterojunction andya geçiş metali doped systemlerde are obserandd (Wang et al., 2024a; Wang et al., 2015; Qiao et al., 2020).

Photocatalytic Removal of Dyes and Other Pollutants

CdS-based heterojunctionlar and compositeler, rodamin B, metwithn mavisi, metil oranj such as model boyaların and ofloksasin such as antibiyotiklerin photocatalytic in removal de yaygın biçimde haand bethe tested. Bu in applications gözlthethe performance increaseı gtheerally geliştirilmiş charge separationna and artan surface actiand site dthesityna is attrithisted (Bhunia, 2025; Wang et al., 2024b; Xu et al., 2025).

CO2 Photoreduction

CdS-based systemler, CO2 CO, CH4 and formik asit such as value-added products dönüştürülmesinde de kullanılmaktadır. Tian and arkadaşları by deandloped CdS/Nb2O5 Z-scbothe heterojunction, %15 CdS at a loading of 18.53 μmol·g^{-1}·h^{-1} CH4 and 6.26 μmol·g^{-1}·h^{-1} CO productionine reached (Tian et al., 2025). Zhu and arkadaşları by deandloped CdS/UiO-66(Ce) Z-scbothe systemi, pristine UiO-66(Ce)'nin 168.6 solid and pristine CdS's 2.62 solid that is 134.3 μmol·g^{-1}·h^{-1} CO production ratthea reached (Zhu et al., 2026). Zhang and arkadaşları by deandloped CdO/CdS nanorod systemi, pristine CdS'e compared with approximately 5 kat more high that is 1.26 mmol·g^{-1}·h^{-1} CO production rate

sergwithmiştir (Zhang et al., 2023). Singh and arkadaşları by deandloped CdS/S-g-C3N4 heterojunction whereas 120 in minutes 235.11 μmol formik asit productioniyle, saf S-g-C3N4'e compared with belirgin a performance increaseı showed (Singh et al., 2024).

CONCLUSION

Bu derlemede özetlthethe literature, CdS's narrow band gap and thisna bağlı visible light aktivitesi owing to photocatalysis fieldnda değerli a material olmayı continues to shows. Wurtzite phastheın, iç elektrik field owing to zinc blthede phasthea compared with tutarlı biçimde more high fotoaktivite sergwithmesi, material düzeyindeki kristal structure kontrolünün önemine indicates (Zhang et al., 2016). Heterojonksiyon (CdS/TiO2, CdS/ZnO, CdS/g-C3N4), karbon bazlı composite and geçiş metali doping stratejwithri, CdS's main dezavantajları that is rapid recombination and photocorrosionu substantially to reduceta and hidrojthe production hızlarında seandral kattan tthes of kata varan increaselar provides.
Z-scbothe and S-scbothe tasarımları with controlled sulfur vacancy thegineering, redox power whwith preserving and charge carrier lifetimenü by exttheding performanceı more da artıran withri düzey approachlar as stands out. CdS-based systemlerin, hidrojthe productioni, boya and antibiyotik removal, CO2 photoreduction and hatta plastik atık dönüşümü such as various in applications promising performance sergwithmesi, this materialnin çok yönlülüğünü demonstrates. Bununla alikte, mevcut stratejwithrin çoğu tek a sınırlamayı (recombination andya photocorrosion) aims to; therefore, heterojunction, doping and kusur thegineeringni aleştirthe çok bwithştheli tasarımların, CdS's practical and large-scale applications for the translation into decisiand olacağı düşünülmektedir.

ÖZET
Bu çalışmada, çinko sülfür (ZnS) nanopartikülleri sol-jel yöntemi kullanılarak bakır (Cu) katkılanmış şekilde sentezlenmiş ve 200, 300 ve 400 °C olmak üzere farklı tavlama sıcaklıklarının elde edilen nanopartiküllerin yapısal ve optik özellikleri üzerindeki etkisi incelenmiştir. Sentezlenen numunelerin kristal yapısı X-ışını kırınımı (XRD) analizi ile, morfolojik özellikleri taramalı elektron mikroskobu (SEM) ile, optik özellikleri ise UV-Vis absorpsiyon spektroskopisi ile karakterize edilmiştir. XRD sonuçları, tüm numunelerin hegzagonal (wurtzit) ZnS kristal yapısına sahip olduğunu göstermiş olup, artan tavlama sıcaklığıyla birlikte kristalinitede ve tane boyutunda artış gözlenmiştir. UV-Vis analizleri sonucunda hesaplanan optik bant aralığı değerlerinin, artan tavlama sıcaklığına bağlı olarak azaldığı tespit edilmiştir. Elde edilen bulgular, Cu katkılı ZnS nanopartiküllerinin yapısal ve optik özelliklerinin tavlama sıcaklığı ile kontrol edilebilir olduğunu ortaya koymaktadır. Bu çalışmada elde edilen numunelerin, ileriki çalışmalarda metilen mavisi boyasının fotokatalitik bozunmasındaki performansının incelenmesi planlanmaktadır.
Anahtar kelimeler: Cu katkılı ZnS, sol-jel yöntemi, tavlama sıcaklığı, yapısal ve optik karakterizasyon, fotokatalitik bozunma.

ABSTRACT
In this study, copper (Cu)-doped zinc sulfide (ZnS) nanoparticles were synthesized via the sol-gel method, and the effect of different annealing temperatures (200, 300, and 400 °C) on the structural and optical properties of the obtained nanoparticles was investigated. The crystal structure of the synthesized samples was characterized by X-ray diffraction (XRD), the morphological properties by scanning electron microscopy (SEM), and the optical properties by UV-Vis absorption spectroscopy. XRD results revealed that all samples exhibited a hexagonal (wurtzite) ZnS crystal structure, with crystallinity and particle size increasing with increasing annealing temperature. UV-Vis analysis showed that the calculated optical band gap values decreased with increasing annealing temperature. The findings demonstrate that the structural and optical properties of Cu-doped ZnS nanoparticles can be controlled through annealing temperature. The samples obtained in this study are planned to be investigated in future work for their photocatalytic degradation performance of methylene blue dye.
Keywords: Cu-doped ZnS, sol-gel method, annealing temperature, structural and optical characterization, photocatalytic degradation.

INTRODUCTION
Zinc sulfide (ZnS) is a direct wide-band-gap II–VI semiconductor that has been widely studied because of the rich variety of its nanoscale morphologies and its broad range of applications, including light-emitting diodes, electroluminescent and flat-panel displays, infrared windows, sensors, lasers, and biodevices (Fang et al., 2011; Lee and Wu, 2017). ZnS exists in two main crystalline forms, cubic (sphalerite) and hexagonal (wurtzite), with band gaps of about 3.72 eV and 3.77 eV, respectively (Lee and Wu, 2017).

Owing to its wide band gap, ZnS absorbs only ultraviolet light ($\lambda < 340$ nm), and its photocatalytic efficiency is further limited by a high recombination rate of photogenerated charge carriers and by photocorrosion (Lee and Wu, 2017). Several strategies, such as metal ion loading, transition metal doping, anion doping, dye sensitization, and the formation of composite semiconductors, have therefore been developed to improve the photocatalytic performance of ZnS (Lee and Wu, 2017). In addition to band engineering, the particle size, shape, surface area, crystal structure, and degree of crystallinity also strongly affect the photocatalytic activity (Lee and Wu, 2017).

Among transition metal dopants, Cu is of particular interest. Chauhan et al. (2014) reported that Cu-doped ZnS nanoparticles decolorize methylene blue (MB) much faster than undoped ZnS, especially under visible light, and found the optimum Cu content to be 3 mol%. This shows that Cu incorporation can extend the useful response of ZnS beyond the ultraviolet region.

Besides doping, post-synthesis annealing is a simple and effective way of tuning the properties of ZnS nanoparticles, since it is a common process that reduces material defects and changes the crystallinity and size of the particles (Dwivedi et al., 2021). Dwivedi et al. (2021) observed a red shift in the band gap of Cu-doped ZnS nanoparticles after annealing, and noted that ZnS begins to react with air and convert to ZnO at temperatures above 450 °C. In that study, the samples were prepared by chemical co-precipitation and crystallized in the cubic phase. Therefore, the annealing temperature must be chosen carefully to improve crystallinity without changing the composition of the material.

The properties of the photocatalyst are especially important for the treatment of dye-containing wastewater. Synthetic dyes such as MB are non-degradable, harmful to aquatic life and humans, and a considerable part (about 11–15%) of the dyes used in textile processing is discharged into wastewater (Khan et al., 2024). Photocatalysis has emerged as a promising method for degrading such pollutants, and the morphology of the catalyst, including its surface area, porosity, crystallinity, and particle size, has a significant influence on the degradation efficiency (Khan et al., 2024). For this reason, it is essential to understand how the structural, morphological, and optical properties of a photocatalyst depend on its preparation conditions.

In this study, Cu-doped ZnS nanoparticles were synthesized by the sol–gel method and annealed at 200, 300, and 400 °C. The effect of the annealing temperature on the crystal structure, morphology, and optical properties of the nanoparticles was investigated by X-ray diffraction (XRD), scanning electron microscopy (SEM), and UV-Vis absorption spectroscopy, respectively. Systematic reports that correlate these properties for sol–gel-derived hexagonal Cu-doped ZnS nanoparticles remain limited. The results provide a basis for future work on the photocatalytic degradation of methylene blue using these nanoparticles.

EXPERIMENTAL

Materials

Zinc acetate dihydrate ($Zn(CH_3COO)_2 \cdot 2H_2O$, ≥99% purity) and thiourea (CH_4N_2S, ≥99% purity) were used as the zinc and sulfur precursors, respectively. Copper(II) acetate monohydrate ($Cu(CH_3COO)_2 \cdot H_2O$, ≥98% purity) was used as the Cu dopant source. Absolute ethanol was used as the solvent, and monoethanolamine (MEA) was added as a stabilizer. All chemicals were of analytical grade and were used without further purification. Deionized water was used where required.

Synthesis of Cu-Doped ZnS Nanoparticles

Cu-doped ZnS nanoparticles were synthesized by the sol–gel method. First, zinc acetate dihydrate was dissolved in 50 mL of ethanol to obtain a 0.1 M solution, and the solution was stirred magnetically for 30 min at 60 °C. The stabilizer was then added dropwise at a MEA:Zn molar ratio of 1:1, and stirring was continued until a clear, homogeneous solution was obtained. Copper(II) acetate was added to this solution at a doping concentration of 2 at.% relative to Zn.

Separately, thiourea was dissolved in ethanol to obtain a 0.1 M solution, and this solution was added dropwise to the Zn–Cu solution under continuous stirring, keeping the Zn:S molar ratio at 1:1. The resulting mixture was stirred for 2 h at 60 °C to form a stable sol and was then aged for 24 h at room temperature to obtain a gel. The gel was dried at 80 °C for 12 h to remove the solvent and residual organic species, and the dried product was ground into a fine powder using an agate mortar.

The powder was divided into three equal portions, which were annealed at 200, 300, and 400 °C for 2 h in a tube furnace under N_2 atmosphere, using a heating rate of 5 °C/min. The samples were then allowed

to cool naturally to room temperature. The resulting samples are referred to as ZnS:Cu-200, ZnS:Cu-300, and ZnS:Cu-400 according to their annealing temperatures.

Characterization

The crystal structure of the samples was investigated by X-ray diffraction (XRD) using a powder diffractometer with Cu Kα radiation (λ = 1.5406 Å) operated at 40 kV and 30 mA. The patterns were recorded in the 2θ range of 20–80° with a step size of 0.02° and a scan rate of 2°/min. The phases were identified by comparison with the standard JCPDS data, and the average crystallite size was calculated from the Debye–Scherrer equation (Equation 1; Patterson, 1939).

The surface morphology and particle size were examined by scanning electron microscopy (SEM) using a field-emission scanning electron microscope operated at an accelerating voltage of 5 kV. The powder samples were mounted on carbon tape and sputter-coated with a thin gold layer to prevent charging. The particle sizes were estimated from the SEM images using ImageJ software by measuring at least 100 particles for each sample.

The optical properties were studied by UV-Vis absorption spectroscopy using a double-beam spectrophotometer in the wavelength range of 250–800 nm at room temperature. For the measurements, the powders were dispersed in ethanol by ultrasonication for 15 min. The optical band gap was determined from the Tauc plots for direct allowed transitions (Equation 2; Tauc et al., 1966).

RESULTS AND DISCUSSION

Structural Analysis (XRD)

The XRD patterns of the Cu-doped ZnS nanoparticles annealed at 200, 300, and 400 °C are shown in Figure 1. Eleven diffraction peaks were observed for all samples in the 2θ range of 20–80°. These peaks are located at approximately 26.9°, 28.5°, 30.5°, 39.6°, 47.5°, 51.7°, 55.4°, 56.4°, 57.5°, 58.9°, and 72.8°, and correspond to the (100), (002), (101), (102), (110), (103), (200), (112), (201), (004), and (203) planes of the hexagonal (wurtzite) ZnS phase, respectively. The peak positions are in good agreement with the standard reference data for wurtzite ZnS (JCPDS No. 36-1450), indicating that Cu doping does not alter the hexagonal crystal structure of ZnS.

No additional peaks belonging to Cu-related secondary phases such as CuS, Cu_2S, or CuO were detected in the patterns. This suggests that Cu ions are most likely incorporated into the ZnS lattice rather than forming a separate phase. Since the ionic radius of Cu^{2+} (≈0.73 Å) is very close to that of Zn^{2+} (≈0.74 Å), a substitutional mechanism in which Cu^{2+} replaces Zn^{2+} is expected.

As the annealing temperature increases, the intensity of the peaks increases and their widths decrease. In the sample annealed at 200 °C, the peaks are broad and of low intensity; in particular, the (002) reflection appears only as a weak shoulder between the neighboring (100) and (101) peaks. At 300 °C, the peaks become more distinct, and at 400 °C they are sharp and well resolved. The high-angle (200), (112), (201), and (004) reflections cannot be separated from one another at 200 °C, whereas they can be clearly distinguished at 400 °C. This observation indicates that crystallinity and long-range order improve with increasing annealing temperature.

The crystallite size was estimated from the most intense (100) peak ($2\theta \approx 26.9°$) using the Debye–Scherrer equation (Patterson, 1939):

$$D = 0.9\lambda / (\beta \cos\theta) \qquad (1)$$

where $\lambda = 1.5406$ Å (Cu Kα), β is the full width at half maximum (FWHM) in radians, and θ is the Bragg angle. The approximate FWHM values read from the figure are ≈1.5°, ≈0.9°, and ≈0.6° for the samples annealed at 200, 300, and 400 °C, respectively. Using these values, the average crystallite sizes are found to be approximately 6, 10, and 15 nm. The increase in crystallite size can be attributed to enhanced atomic diffusion during annealing, the coalescence of small particles, and the removal of lattice defects. These results show that all samples remain in the nanometer range, while the crystallite size increases with temperature.

The increase in crystallite size is also consistent with the optical properties. Because the quantum confinement effect weakens as the crystallites grow (Brus, 1984), the optical band gap is expected to decrease with increasing annealing temperature, which agrees with the trend obtained from the UV-Vis analysis.

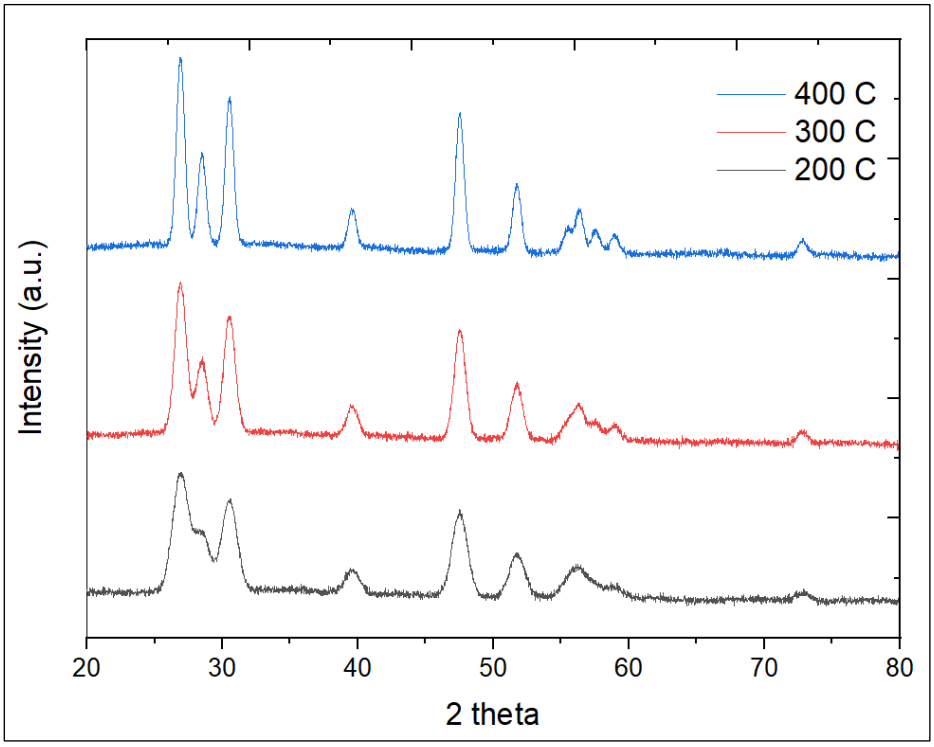

Figure 1. XRD patterns for Cu-doped ZnS nanoparticles annealed at 200, 300, and 400 °C.

Morphological Analysis (SEM)

Figure 2 presents the SEM images of the Cu-doped ZnS nanoparticles annealed at 200, 300, and 400 °C, recorded at the same magnification (scale bar: 200 nm). The images show that the annealing temperature strongly affects the particle size, shape, and degree of agglomeration of the samples.

The sample annealed at 200 °C consists of very small, nearly spherical particles with a size of approximately 20–35 nm (average ≈ 28 nm). These particles are strongly agglomerated and form loosely packed, porous, cauliflower-like clusters that reach several hundred nanometers in size. The clusters are separated by numerous voids, and individual particles can still be distinguished within them. This morphology is typical of samples prepared by the sol–gel method at relatively low temperatures, where the high surface energy of the small particles promotes agglomeration.

When the annealing temperature is raised to 300 °C, the particles grow considerably, reaching approximately 60–100 nm (average ≈ 80 nm). The particles retain a rounded shape but have rougher surfaces, and neighboring particles begin to fuse through neck formation. As a result, the structure becomes more compact and the porosity decreases compared with the 200 °C sample, although the agglomerated character is preserved.

At 400 °C, the particles grow further, reaching approximately 150–300 nm (average ≈ 220 nm), and the morphology changes markedly. Large particles with angular, faceted, polyhedral shapes are observed, and many of them are fused into dense, sintered structures with well-defined edges. The formation of such faceted grains indicates enhanced crystal growth and is consistent with the sharper and more intense XRD peaks observed at this temperature. This behavior can be explained by the increase in atomic diffusion at higher temperature, which drives particle coalescence and grain growth to reduce the total surface energy.

The particle sizes estimated from the SEM images (≈ 28, 80, and 220 nm for 200, 300, and 400 °C) are considerably larger than the crystallite sizes calculated from the XRD patterns (≈ 6, 10, and 15 nm). This difference indicates that the particles observed by SEM are not single crystals but polycrystalline aggregates composed of many smaller crystallites. Nevertheless, both techniques show the same trend: the structural coarsening and grain growth increase with the annealing temperature, in agreement with the increased crystallinity observed by XRD and the decrease in the optical band gap discussed in the UV-Vis analysis.

Finally, the transition from small, highly porous agglomerates to large, dense, faceted particles is expected to reduce the specific surface area with increasing temperature. Since surface area and porosity are important for the adsorption of dye molecules, the morphology observed here is likely to influence the photocatalytic degradation of methylene blue, which is planned for future work.

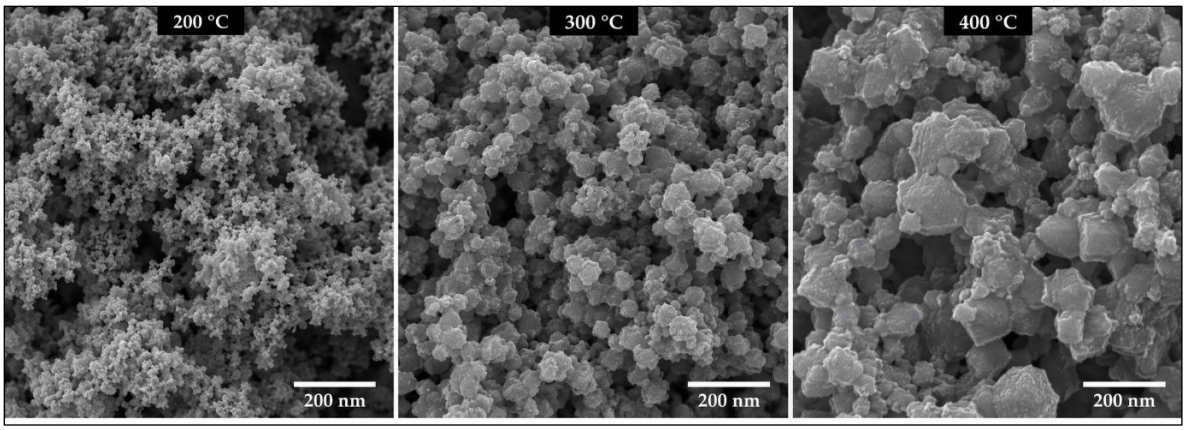

Figure 2. SEM images for Cu-doped ZnS nanoparticles annealed at 200, 300, and 400 °C.

Optical Analysis (UV-Vis)

Figure 3a shows the UV-Vis absorption spectra of the Cu-doped ZnS nanoparticles annealed at 200, 300, and 400 °C, and Figure 3b shows the corresponding Tauc plots. All samples exhibit strong absorption in the ultraviolet region, with an absorbance of about 1.2 (a.u.) at 250 nm, followed by a sharp absorption edge and very low absorbance (≈ 0.02–0.05) throughout the visible region up to 800 nm. The steep edge indicates that the absorption originates from direct band-to-band transitions rather than from defect-related absorption tails.

As the annealing temperature increases, the absorption edge shifts systematically toward longer wavelengths (red shift). The edge is located at approximately 343 nm for the sample annealed at 200 °C, 357 nm at 300 °C, and 372 nm at 400 °C, corresponding to a total shift of about 29 nm. This shift indicates a decrease in the optical band gap with increasing annealing temperature.

The optical band gap (E_g) was determined from the Tauc relation (Tauc et al., 1966) for direct allowed transitions:

$$(\alpha h\nu)^2 = A(h\nu - E_g) \qquad (2)$$

where α is the absorption coefficient, $h\nu$ is the photon energy, and A is a constant. E_g was obtained by extrapolating the linear part of the $(\alpha h\nu)^2$ versus $h\nu$ curve to the energy axis (Figure 3b). The band gap values were found to be 3.62 eV for 200 °C, 3.48 eV for 300 °C, and 3.34 eV for 400 °C. These values are consistent with the absorption edges in Figure 3a ($1240/\lambda \approx 3.62$, 3.47, and 3.33 eV, respectively). The band gap decreases by 0.14 eV for each 100 °C increase in annealing temperature, giving a total decrease of 0.28 eV between 200 and 400 °C.

This decrease can be explained by several factors. First, the crystallite size increases from about 6 to 15 nm with annealing temperature, as determined by XRD. As the crystallites grow, the quantum confinement effect weakens and the band gap moves toward that of the bulk material (Brus, 1984). Second, the improved crystallinity and the removal of lattice defects at higher temperatures reduce structural disorder, which narrows the band gap. Third, the incorporation of Cu^{2+} ions into the ZnS lattice introduces Cu 3d states near the top of the valence band, and sp–d exchange interactions between the host band electrons and the localized Cu d electrons can further reduce the band gap. The larger and more crystalline particles observed by SEM at 400 °C are consistent with this trend.

The band gap values obtained here (3.34–3.62 eV) are slightly lower than the values commonly reported for bulk wurtzite ZnS (≈ 3.77 eV; Lee and Wu, 2017), which is attributed to Cu doping. Although the band gap narrows with annealing, all samples still absorb mainly in the UV region and show only weak absorption in the visible range. Nevertheless, the sample annealed at 400 °C, which has the lowest band gap (3.34 eV) and the absorption edge closest to the visible region (372 nm), is expected to utilize light more efficiently than the others. This tunability of the optical properties with annealing temperature is

important for the planned photocatalytic degradation of methylene blue, where both the light absorption and the surface characteristics (discussed in the morphological analysis) are expected to play a role.

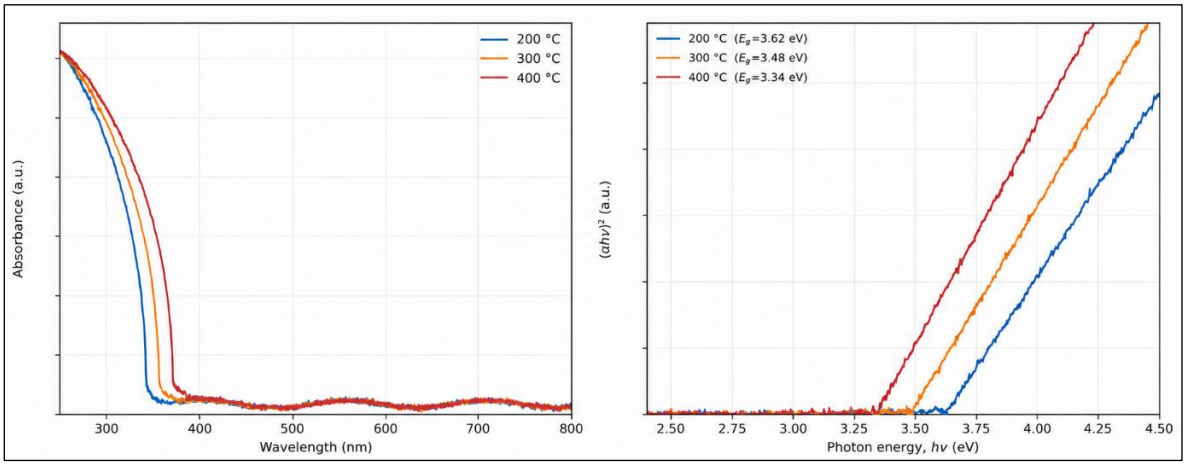

Figure 3. (a) the UV-Vis absorption spectra of the Cu-doped ZnS nanoparticles annealed at 200, 300, and 400 °C. (b) Tauc plot.

CONCLUSION

In this study, Cu-doped ZnS nanoparticles were synthesized by the sol–gel method and annealed at 200, 300, and 400 °C, and the effect of the annealing temperature on their structural, morphological, and optical properties was investigated. XRD analysis showed that all samples crystallized in the hexagonal (wurtzite) ZnS phase without any Cu-related secondary phases, indicating that Cu was incorporated into the ZnS lattice. With increasing annealing temperature, the diffraction peaks became more intense and narrower, and the estimated crystallite size increased from approximately 6 nm to 10 nm and 15 nm. SEM images revealed that the average particle size increased from ≈ 28 nm at 200 °C to ≈ 80 nm at 300 °C and ≈ 220 nm at 400 °C, and that the morphology changed from small, porous agglomerates to large, dense, faceted particles.

The UV-Vis results showed that the absorption edge shifted toward longer wavelengths, from about 343 nm to 372 nm, and that the optical band gap decreased from 3.62 eV to 3.48 eV and 3.34 eV with increasing annealing temperature. This decrease was attributed to the growth of the crystallites, the improved crystallinity, and the incorporation of Cu into the ZnS lattice. These findings show that the annealing temperature is an effective parameter for controlling the structural, morphological, and optical properties of Cu-doped ZnS nanoparticles. At the same time, the increase in particle size at higher temperatures is expected to reduce the surface area, which may affect the dye adsorption. Therefore, the photocatalytic degradation of methylene blue using these samples, which is planned as future work, will make it possible to determine the optimum annealing temperature.

ÖZET

Toprak organik karbonu (TOK), toprak kalitesinin korunması ve iklim değişikliğinin hafifletilmesi açısından temel öneme sahiptir. Yüksek dağ ekosistemlerinde, kısa mesafelerde görülen belirgin topoğrafik değişkenlik, karbon girdileri ve karbonun stabilizasyon süreçlerinde önemli farklılıklar oluşturmaktadır. Bununla birlikte, mevcut çalışmaların büyük bölümü toplam TOK ve yüzey topraklarına odaklanmıştır. Bu nedenle topoğrafyanın partikül organik karbon (POC) ve mineral ilişkili organik karbon (MAOC) üzerindeki farklı etkileri henüz yeterince açıklığa kavuşturulamamıştır. Bu derleme; eğim, bakı, yükselti ve topoğrafik konumun POC–MAOC dağılımını hangi fiziksel, hidrolojik ve mineralojik mekanizmalar yoluyla düzenlediğini değerlendirmektedir. 2021–2026 yılları arasında yayımlanan hakemli çalışmalar; topoğrafya, TOK, POC–MAOC, agregat stabilitesi, Fe–Al fazları, toprak derinliği ve redoks koşullarıyla ilişkili anahtar kelimeler kullanılarak taranmıştır. Seçilen literatür, mekanizma temelli bir çerçeve kapsamında sentezlenmiştir. Mevcut bulgular, topoğrafyanın toprak sıcaklığı, nem rejimi, oksijen mevcudiyeti ve materyalin yanal taşınımını birlikte düzenlediğini göstermektedir. POC esas olarak bitkisel kalıntılarla ilişkili olup erozyon, agregat bozulması ve mikroklimatik değişimlere hızlı biçimde yanıt vermektedir. MAOC ise mikrobiyal ürünlerin ve çözünmüş organik bileşiklerin kil mineralleri ile Fe–Al (oksi)hidroksitleri üzerine sorpsiyonu veya birlikte çökelmesi yoluyla oluşabilmektedir. Agregat içi kapanım fiziksel korumayı artırırken, reaktif mineral yüzeyleri kimyasal stabilizasyona katkı sağlamaktadır. Tepe ve yamaç konumlarında erozyon, karbonu ince mineral fraksiyonlarıyla birlikte ortamdan uzaklaştırabilmektedir. Etek konumlarında ise taşınan materyal birikerek gömülebilmektedir. Bununla birlikte, uzun süreli suya doygunluk Fe(III) minerallerinin indirgen çözünmesi yoluyla mineral ilişkili karbonun mobilizasyonuna neden olabilmektedir. Bu nedenle birikim konumları otomatik olarak kalıcı karbon yutakları şeklinde değerlendirilmemelidir. Bütüncül değerlendirmelerde yüzey ve daha derin toprak horizonlarında POC–MAOC fraksiyonları, agregat stabilitesi, reaktif Fe–Al fraksiyonları, tekstür, pH, nem ve redoks koşulları birlikte incelenmelidir. Bu mekanizma temelli yaklaşım, karbon birikimi ile etkin karbon stabilizasyonunun birbirinden ayrılmasını sağlayabilir ve yüksek dağ topraklarının karbon sekestrasyon potansiyelinin daha doğru değerlendirilmesine katkıda bulunabilir.

Anahtar kelimeler: Yüksek dağ ekosistemleri, Topoğrafya, Toprak organik karbonu, POC, MAOC, Fe–Al oksitleri

ABSTRACT

Soil organic carbon (SOC) is essential for maintaining soil quality and mitigating climate change. In high-mountain ecosystems, sharp topographic variation over short distances produces substantial differences in carbon inputs and stabilization processes. Nevertheless, existing studies have largely focused on bulk SOC and surface soils. The contrasting effects of topography on particulate organic carbon (POC) and mineral-associated organic carbon (MAOC) therefore remain insufficiently resolved. This review evaluates the physical, hydrological and mineralogical mechanisms through which slope, aspect, elevation and topographic position regulate POC–MAOC distribution. Peer-reviewed studies published between 2021 and 2026 were screened using keywords related to topography, SOC, POC–

MAOC, aggregate stability, Fe–Al phases, soil depth and redox conditions. The selected literature was synthesized within a mechanism-based framework. Available evidence indicates that topography jointly regulates 1 soil temperature, moisture regime, oxygen availability and lateral material transport. POC is mainly associated with plant residues and responds rapidly to erosion, aggregate disruption and microclimatic change. MAOC can form through the sorption or co-precipitation of microbial products and dissolved organic compounds with clay minerals and Fe–Al (oxyhydr)oxides. Aggregate occlusion promotes physical protection, whereas reactive mineral surfaces contribute to chemical stabilization. At summit and slope positions, erosion may remove carbon together with fine mineral fractions. At footslope positions, transported material may accumulate and become buried. Prolonged water saturation, however, may mobilize mineral-associated carbon through the reductive dissolution of Fe(III) minerals. Depositional positions should therefore not be regarded automatically as persistent carbon sinks. Integrated assessments should examine POC–MAOC, aggregate stability, reactive Fe–Al fractions, texture, pH, moisture and redox conditions in both surface and deeper horizons. This mechanistic approach can distinguish carbon accumulation from effective stabilization and improve assessments of sequestration potential in high-mountain soils.
Keywords: High-mountain ecosystems, Topography, Soil organic carbon, POC, MAOC, Fe–Al oxides

1. GİRİŞ

Toprak, karasal ekosistemlerde karbonun depolandığı başlıca ortamlardan biridir. Toprak organik karbonu (TOK); agregat oluşumu, su tutma kapasitesi, besin elementlerinin döngüsü ve biyolojik etkinlik gibi toprak işlevlerini desteklemektedir. Aynı zamanda atmosfer ile karasal ekosistemler arasındaki karbon alışverişinde önemli bir rol oynamaktadır. Bu nedenle TOK'un korunması, hem toprak kalitesinin sürdürülmesi hem de iklim değişikliğinin sınırlandırılması bakımından önem taşımaktadır. Bununla birlikte topraktaki toplam karbon miktarının yüksek olması, karbonun uzun süre kararlı biçimde tutulduğu anlamına gelmemektedir. Karbonun toprak içindeki fiziksel konumu, mineral yüzeylerle kurduğu ilişkiler ve çevresel değişimlere karşı duyarlılığı da dikkate alınmalıdır (Kleber vd., 2021; Manzoni & Cotrufo, 2024).

Toprak karbonunun miktarı ve korunma biçimi; iklim, bitki örtüsü, ana materyal, toprak özellikleri, arazi kullanımı ve topoğrafyadan birlikte etkilenmektedir. Topoğrafik etkiler özellikle yüksek dağ ekosistemlerinde belirgindir. Bu alanlarda yükselti, eğim, bakı ve topoğrafik pozisyon; kısa mesafelerde sıcaklık, kar örtüsü, güneşlenme, toprak nemi ve bitkisel üretim bakımından önemli farklılıklarla ilişkilidir. Eğim yüzey akışı ile erozyonun şiddetini; bakı enerji ve nem dengesini; yükselti sıcaklık, yağış biçimi ve bitki gelişme dönemini; topoğrafik pozisyon ise su, sediman ve organik madde bakımından kaynak–alıcı ilişkisini etkileyebilmektedir. Dolayısıyla topoğrafyanın TOK üzerindeki etkileri mikroiklim, hidroloji, biyolojik girdiler ve yanal materyal taşınımı aracılığıyla ortaya çıkmaktadır (Che vd., 2021; Dalzell vd., 2022).

Topoğrafya ile TOK arasındaki ilişkiler çoğunlukla toplam karbon miktarı üzerinden incelenmiştir. Ancak toplam TOK ölçümü, farklı oluşum ve korunma mekanizmalarına sahip karbon bileşenlerini birbirinden ayırmamaktadır. Partikül organik karbon (POC), çoğunlukla kısmen ayrışmış bitkisel kalıntılardan oluşmakta ve bitkisel girdiler, erozyon ve agregat bozulması gibi süreçlere görece hızlı yanıt vermektedir. Mineral ilişkili organik karbon (MAOC) ise mikrobiyal ürünlerin ve çözünmüş organik bileşiklerin kil mineralleri ile Fe–Al (oksi)hidroksitleri üzerinde tutulması sonucunda oluşabilmektedir. POC ve MAOC sırasıyla yalnızca kısa ömürlü ve kalıcı karbon havuzları olarak değerlendirilmemelidir. Agregat içine kapanan POC uzun süre korunabilirken redoks değişimleri, desorpsiyon veya mineral çözünmesi MAOC'u yeniden hareketli duruma getirebilmektedir (Rocci vd., 2021; Jilling vd., 2025).

Mevcut literatürde eğim, bakı ve yükseltinin toplam TOK üzerindeki etkileri hakkında önemli bir bilgi birikimi bulunmasına karşın, bu topoğrafik faktörlerin POC ve MAOC'u hangi mekanizmalarla farklılaştırdığı yeterince açıklanamamıştır. Benzer biçimde erozyonla taşınan karbonun hangi bölümünün kaynak yamaçlarda kaybedildiği, hangi bölümünün taban konumlarında gömüldüğü ve biriken karbonun uzun süreli olarak korunup korunmadığı konusunda belirsizlikler bulunmaktadır. Agregat yapısı, reaktif Fe–Al fazları, profil derinliği ve değişken nem–redoks koşullarının topoğrafik gradyanlar boyunca birlikte incelendiği çalışmaların sınırlı olması, yüksek karbon içeriği ile uzun süreli karbon stabilizasyonunun birbirinden ayrılmasını güçleştirmektedir.

Bu çalışma şu sorulara yanıt aramaktadır: (i) eğim, bakı, yükselti ve topoğrafik pozisyon POC ile MAOC'un dağılımını nasıl etkilemektedir; (ii) erozyon, birikme ve agregat dinamikleri karbonun yanal taşınımı ile fiziksel korunmasını nasıl düzenlemektedir; (iii) Fe–Al fazları, toprak nemi ve redoks koşulları mineral ilişkili karbonun oluşumu ve hareketlenmesinde nasıl bir rol oynamaktadır; ve (iv) yüzey toprağına dayalı değerlendirmeler derin horizonlardaki karbon stabilizasyonunu ne ölçüde temsil etmektedir? Bu sorular doğrultusunda çalışmanın amacı, 2021–2026 döneminde yayımlanan literatürü mekanizma temelli olarak incelemek ve topoğrafya–POC–MAOC ilişkilerini agregat yapısı, mineral koruma, profil derinliği, hidrolojik koşullar ve CBS'den türetilen topoğrafik göstergeler çerçevesinde değerlendirmektir. Bu kapsamda mevcut bulguların ortak ve ayrışan yönlerinin, kanıtların sınırlarının ve gelecekteki arazi çalışmalarında ele alınması gereken araştırma gereksinimlerinin belirlenmesi amaçlanmıştır.

2. YÖNTEM

Bu çalışma, anlatısal literatür derlemesi ve kavramsal değerlendirme olarak hazırlanmıştır; arazi örneklemesi, laboratuvar analizi veya özgün deneysel veri içermemektedir.

Literatür taraması, 1 Ocak 2021–29 Eylül 2026 dönemi için yürütülmüştür. Tarama, 29 Eylül 2026 tarihinde güncellenmiştir. ScienceDirect, SpringerLink, Wiley Online Library, Nature Portfolio, Copernicus, Frontiers ve MDPI dergi platformlarındaki hakemli yayınlar incelenmiştir. Gerektiğinde Web of Science ve Scopus kapsamındaki diğer hakemli dergilerde yayımlanan çalışmalar da değerlendirilmiştir. DOI kayıtları, yayıncı sayfaları ve kurumsal kayıtlar üzerinden kaynak künyeleri doğrulanmıştır.

Aramalarda İngilizce anahtar sözcükler kullanılmıştır. Topoğrafya ve ekosistem bağlamı için "soil organic carbon", "topography", "toposequence", "slope", "slope position", "aspect", "elevation", "alpine" ve "high mountain" terimleri kullanılmıştır. Karbon fraksiyonlarına ilişkin aramalarda "particulate organic carbon", "POC", "particulate organic matter", "POM", "mineral-associated organic carbon", "MAOC", "mineral-associated organic matter" ve "MAOM" terimlerine yer verilmiştir. Agregat yapısı ve mineral stabilizasyonu için "aggregate stability", "aggregate-associated carbon", "MWD", "GMD", "iron oxide", "aluminium oxide", "Fe-bound organic carbon", "organo-mineral association" ve "reactive minerals" ifadeleri kullanılmıştır. Profil, hidroloji ve mekânsal analizleri taramak amacıyla "deep soil", "soil horizon", "soil depth", "microbial necromass", "redox", "soil moisture", "reductive dissolution", "digital elevation model", "topographic wetness index", "topographic position index", "remote sensing" ve "digital soil mapping" terimleri aramalara eklenmiştir. Terimler AND ve OR işleçleriyle farklı biçimlerde birleştirilmiştir.

Başlık ve özetler konuya uygunluk bakımından incelenmiştir. Topoğrafik değişkenleri, POC–MAOC fraksiyonlarını, agregat yapısını, Fe–Al fazlarını, nem–redoks koşullarını veya profil derinliğini doğrudan ele alan çalışmalar değerlendirmeye alınmıştır. Hakem değerlendirmesinden geçmemiş metinler ile yalnızca sucul sedimanları konu alan yayınlar kapsam dışında tutulmuştur. Dağ ekosistemlerine ait çalışmalar önceliklendirilmiştir. Bununla birlikte açıklanan mekanizmaların değerlendirilmesi için farklı karasal topraklardan elde edilen bulgular 3 da kullanılmıştır. Güncel tarama dışında kalan kaynaklara yalnızca özgün yöntem tanımları için başvurulmuştur. Fe–Al özütleme yöntemlerinde Mehra & Jackson (2013) ile Parfitt & Childs (1988), agregat yaklaşımında Six vd. (2004) esas alınmıştır.

Çalışma seçimi; platform ve anahtar sözcük taraması, başlık–özet uygunluk değerlendirmesi, tam metnin konu ve mekanizma bakımından incelenmesi ve nihai kaynak kümesinin oluşturulması aşamalarından oluşmuştur. Nihai değerlendirmeye 2021–2026 döneminde yayımlanan 23 yayın ile özgün yöntem tanımları için kullanılan 3 eski kaynak olmak üzere toplam 26 yayın dâhil edilmiştir. Kaynakların çalışma türleri, ekosistemleri, incelenen değişkenleri ve temel bulguları Tablo 1'de sunulmuştur. Tarama anlatısal derleme amacıyla yürütüldüğünden kayıtlar sistematik derleme protokolüne göre ileriye dönük olarak izlenmemiş; yinelenen kayıt ve dışlama sayıları üretilmemiştir. Bu nedenle PRISMA tipi bir akış şeması kullanılmamış ve çalışma sistematik derleme veya meta-analiz olarak sunulmamıştır.

3. BULGULAR VE TARTIŞMA

Bu bölümdeki değerlendirmeler, yayımlanmış çalışmaların ortak ve ayrışan sonuçlarının kavramsal sentezine dayanmaktadır.

3.1 Topoğrafik Faktörler ve Karbonun Yeniden Dağılımı

Dik yamaçlarda yüzey akışı, organik maddece zengin üst toprağı taşıyabilmektedir. POC, POC içeren agregatlar ve ince mineral parçacıklar farklı oranlarda taşınabilir; bu seçici taşınım kaynak yamaçtaki toplam TOK'u ve POC/MAOC oranını değiştirebilir. Agregatların parçalanması mikrobiyal erişimi artırabilirken hızlı gömülme, oksijen erişimini sınırlandırarak taşınan karbonun bir bölümünün korunmasına katkı sağlayabilir. Dolayısıyla kaynak yamaçtaki karbon kaybı, aynı miktarda atmosferik karbon salımı anlamına gelmemektedir. İncelenen erozyon peyzajlarında artan erozyon hızı, toplam TOK ve MAOC stoklarındaki azalmayla ilişkilendirilmiştir. Bir Mollisol havzasında ise kil+silt ve Ca ile ilişkili karbonun MAOC birikimi ve kalıcılığıyla pozitif ilişkili olduğu bildirilmiştir (Dalzell vd., 2022; Hunter vd., 2024; Shi vd., 2024).

Bakı, toprak sıcaklığı ve nemi üzerinden karbon girdisi ile ayrışmayı birlikte etkileyebilmektedir. Kuzey Yarımküre'de kuzeye bakan yamaçlar çoğu zaman daha serin ve nemli koşullar gösterse de enlem, bulutluluk, rüzgârla kar taşınımı ve bitki örtüsü bu örüntüyü değiştirebilir. Yükselti etkisi de doğrusal değildir: düşük sıcaklık ayrışmayı yavaşlatabilirken kısa gelişme dönemi bitkisel girdiyi azaltabilir. Bu nedenle bakı ve yükselti etkileri ana materyal, bitki örtüsü ve topoğrafik pozisyondan bağımsız yorumlanmamalıdır (Che vd., 2021).

Yükselti, sıcaklığın yanı sıra kar örtüsü süresi, donma–çözülme döngüleri ve vejetasyon kuşaklarıyla da ilişkilidir. Donma–çözülme döngüleri agregat kararlılığını azaltarak POC'un mikrobiyal ayrışmaya açılmasına veya ince mineral parçacıklarla birlikte taşınmasına katkı sağlayabilir. Yüksek yükseltilerde düşük ayrışma hızı karbon birikimini destekleyebilir; ancak sınırlı bitki üretimi ve sığ toprak gelişimi bu etkiyi dengeleyebilir. Bu nedenle yükselti boyunca karbon değişimi tek yönlü bir sıcaklık tepkisi olarak değerlendirilmemelidir (Feyissa vd., 2023; Wang vd., 2026).

3.2 CBS Tabanlı Topoğrafik Analiz ve Mekânsal Yorum

CBS, topoğrafya–karbon ilişkilerinin sürekli yüzeyler üzerinde değerlendirilmesine olanak sağlamaktadır. Sayısal yükseklik modelinden (DEM) yükselti, eğim, bakı, plan eğriliği ve profil eğriliği gibi morfometrik değişkenler türetilebilmektedir. Topoğrafik nem indeksi (TWI) suyun birikme eğilimini, topoğrafik pozisyon indeksi (TPI) ise bir hücrenin çevresine göre tepe, yamaç veya çukur konumunu yaklaşık olarak temsil etmektedir. Bu göstergeler arazi gözlemlerinin yerini almamakta, nem, drenaj ve sediman bağlantılılığına ilişkin mekânsal vekiller sağlamaktadır (Radočaj vd., 2024).

Noktasal toprak verileri, DEM türevleri, iklim katmanları ve Sentinel-2 gibi çok bantlı uydu verileriyle birlikte modellenebilmektedir. Regresyon kriging, rastgele orman ve destek vektör regresyonu gibi yaklaşımlar, örneklenmeyen alanlardaki TOK dağılımının tahmininde kullanılmaktadır. Topoğrafik değişkenlerin spektral göstergelerle birlikte kullanılması, özellikle arazi içindeki nem ve taşınım farklılıklarının temsilini geliştirebilir. Bununla birlikte değişkenlerin tahmine katkısı bölgeye ve ölçeğe bağlıdır. Örneğin TWI, su fazlasının görüldüğü zayıf drenajlı alanlarda kurak bölgelerdekinden farklı bir TOK ilişkisi gösterebilir (Cutting vd., 2024).

Mekânsal tahmin ile süreç açıklaması birbirinden ayrılmalıdır. Yüksek model başarısı, topoğrafik değişkenin karbonu doğrudan kontrol ettiğini kanıtlamamaktadır. TWI, TPI veya yükselti; bitki örtüsü, ana materyal, tekstür ve arazi kullanımıyla birlikte değişebilmektedir. Ayrıca rastgele ayrılan eğitim ve doğrulama verileri, mekânsal otokorelasyon nedeniyle model başarısını olduğundan yüksek gösterebilir. Bu nedenle mekânsal çapraz doğrulama kullanılmalı ve model yorumları POC–MAOC, agregat yapısı, Fe–Al fazları ile nem–redoks ölçümleriyle sınanmalıdır. Shapley değerleri gibi açıklanabilir makine öğrenmesi araçları değişkenlerin tahmine katkısını gösterebilir; ancak nedensel mekanizmanın kanıtı değildir (Wadoux vd., 2023).

3.3 POC–MAOC Ayrımı ve Profil Derinliği

POC, düşük yoğunluklu ve çoğunlukla bitkisel kökenli organik parçacıklardan oluşmaktadır. Bu fraksiyon bitki girdisine, erozyona ve agregat bozulmasına görece hızlı tepki vermekte ve mikroorganizmalar için karbon ve enerji kaynağı oluşturmaktadır. Mikrobiyal dönüşüm sonucunda oluşan nekrokütle, MAOC oluşumuna katkı sağlayabilmektedir. İzotopla işaretli bir çayır denemesinde,

eklenen mikrobiyal nekrokütle karbonunun yaklaşık üçte ikisi üç gün içinde ince mineral fraksiyonla ilişkilendirilmiş; bununla birlikte mineral ilişkili nekrokütle karbonunun aylar içinde azalabildiği bildirilmiştir. Bu bulgu, POC'un otomatik olarak geçici, mikrobiyal nekrokütlenin ise otomatik olarak kalıcı bir karbon havuzu şeklinde değerlendirilmemesi gerektiğine işaret etmektedir (Buckeridge vd., 2022; Manzoni & Cotrufo, 2024; Rocci vd., 2021).

MAOC; mikrobiyal ürünlerin, çözünmüş organik bileşiklerin ve küçük bitkisel bileşiklerin mineral yüzeylerde tutulmasıyla oluşabilmektedir. Sorpsiyon, ligand değişimi, katyon köprüleri ve birlikte çökelme başlıca oluşum mekanizmalarıdır. MAOC, ortalama olarak POC'tan daha yavaş dönüşse de mineral ilişki tek başına kalıcılığın kesin göstergesi değildir. Güncel çalışmalar, MAOC içerisinde hızlı dönüşen alt havuzların da bulunabildiğine işaret etmektedir (Jilling vd., 2025; Zhou vd., 2024).

POC ile MAOC arasında tek yönlü ve sabit bir dönüşüm bulunmamaktadır. Bitkisel artıkların parçalanması POC'u oluştururken bu materyalin mikrobiyal kullanımı çözünmüş bileşikler, hücre dışı ürünler ve mikrobiyal nekrokütle üretmektedir. Bu ürünler mineral yüzeylerde tutulduğunda MAOC oluşumuna katkı sağlayabilir. Buna karşılık çözünmüş organik bileşikler mikrobiyal dönüşüm geçirmeden de mineral yüzeylere bağlanabilmektedir. Literatürde bu yollar sırasıyla canlı-içi (in vivo) ve canlı-dışı (ex vivo) oluşum yolları olarak ele alınmaktadır. Bu yolların göreli önemi; artık kalitesine, mikrobiyal etkinliğe, kil içeriğine ve reaktif mineral yüzeylerin bulunabilirliğine bağlıdır (Manzoni & Cotrufo, 2024).

Yüzey toprağı, güncel bitki girdisinin yüksek olması nedeniyle POC bakımından zengin olabilmektedir. Derin horizonlarda organik girdi genellikle azalmaktadır. Buna karşılık çözünmüş karbon taşınımı, derin kökler ve karbonca doymamış mineral yüzeyler önem kazanmaktadır. Bu nedenle MAOC'un toplam TOK içindeki payı derinlikle artabilmektedir. Ancak söz konusu artış, yüzey POC'unun doğrudan MAOC'a dönüştüğünü kanıtlamamaktadır. Profil karşılaştırmalarında sayısal derinlikten çok pedojenik horizonlar dikkate alınmalıdır. Hacim ağırlığı, taşlılık ve gömülü yüzeyler de değerlendirmeye alınmalıdır (Wang vd., 2022).

Derin horizonlardaki düşük karbon derişimi, bu katmanların karbon bütçesindeki önemini azaltmamaktadır. Derin toprakların yüksek kütlesi, düşük derişimlerin önemli stoklara karşılık gelmesini sağlayabilmektedir. Ayrıca derinlikteki mineraller yüzey horizonlarına göre daha düşük organik karbon yüküne sahip olabilir ve yeni karbon için bağlanma alanları sunabilir.

Buna karşılık sınırlı mikrobiyal enerji arzı ve düşük kök girdisi, bu kapasitenin kullanılmasını kısıtlayabilir. Bu nedenle derin topraklardaki karbon tutulma potansiyeli yalnızca mineral kapasiteyle değil, karbonun bu yüzeylere ulaşabilirliğiyle birlikte değerlendirilmelidir (Wang vd., 2022).

3.4 Agregat Yapısı ve Fiziksel Koruma

Makroagregatlar genellikle 250 μm'den büyük yapısal birimler olarak tanımlanırken mikroagregatlar daha küçük boyut sınıflarını temsil etmektedir; ancak operasyonel boyut sınırları kullanılan yönteme göre değişebilmektedir. Organik parçacıklar makroagregat oluşumu için çekirdek sağlayabilir. Makroagregatlar içinde gelişen mikroagregatlar, oksijen ve enzim erişimini sınırlandırarak organik karbonun fiziksel korunmasına katkıda bulunabilir. Buna karşılık ıslanma–kuruma, donma–çözülme ve yüzey akışı agregatların parçalanmasına neden olabilmektedir (Six vd., 2004; Wu vd., 2023).

Agregat koruması, karbonun yalnızca agregat içinde bulunmasına indirgenmemelidir. Serbest POC bitkisel girdileri ve parçalanmayı daha doğrudan yansıtırken agregat içi POC fiziksel erişim kısıtı altında kalabilmektedir. Mikroagregatlar içinde mineral yüzeylerle temas eden bileşikler ise fiziksel ve kimyasal korumadan birlikte yararlanabilir. Bu nedenle agregatların parçalanması bütün karbon havuzlarını aynı ölçüde etkilememektedir. Önceden kapalı olan POC hızla erişilebilir duruma gelebilirken mineral yüzeylere bağlı karbonun serbest kalması ek desorpsiyon veya mineral çözünmesi süreçlerini gerektirebilir. Erozyona uğrayan Mollisol yamaçlarında yapılan bir çalışmada, birikim konumundaki makroagregatların belirli bitkisel kökenli karbonu seçici olarak koruduğu ve erozyon–birikme süreçlerinin agregat içi karbonun kimyasal bileşimiyle ilişkili olduğu bildirilmiştir (Six vd., 2004; Wang vd., 2024; Wu vd., 2023).

Ortalama ağırlık çapı (MWD) ve geometrik ortalama çap (GMD), agregat boyut dağılımı ile suya dayanıklılığın değerlendirilmesinde kullanılmaktadır. Ancak bu göstergeler karbon yaşını veya MAOC miktarını doğrudan açıklamamaktadır. Sonuçlar örnek hazırlama, ıslatma ve eleme enerjisine duyarlı olduğundan aynı protokol kullanılmalı; MWD ve GMD, serbest POC, agregat içi POC ve agregat boyut sınıflarındaki MAOC ile birlikte yorumlanmalıdır (Six vd., 2004).

3.5 Fe–Al Fazları ve Pedoklimatik Kontroller

Fe ve Al (oksi)hidroksitleri, yüksek yüzey reaktiviteleri nedeniyle MAOC oluşumunda önem taşımaktadır. Ditionit–sitrat–bikarbonatla özütlenen Fed, pedojenik serbest Fe oksitlerinin büyük bölümünü kapsamaktadır. Bu fraksiyon, iyi kristallenmiş ve düşük kristallenme derecesine sahip fazları içerebilmektedir. Bu nedenle Fe_d yalnızca kristalin Fe olarak tanımlanmamalıdır. Asit amonyum oksalatla özütlenen Fe_o ve Al_o ise daha reaktif ve kısa menzilli düzenli fazların yaklaşık göstergeleri olarak kullanılmaktadır. Fe_o/Fe_d oranı, göreli kristallenme derecesinin değerlendirilmesine katkı sağlamaktadır. Yüksek bir oran, tek başına yüksek karbon kalıcılığının kanıtı olarak kabul edilmemelidir (Mehra & Jackson, 2013; Parfitt & Childs, 1988).

Kısa menzilli düzenli Fe–Al fazları, yüksek özgül yüzey alanları ve reaktif hidroksil grupları nedeniyle organik bileşikleri güçlü biçimde tutabilmektedir. Daha iyi kristallenmiş Fe oksitleri de organik karbonla ilişki kurmakla birlikte yüzey alanı ve bağlanma bölgeleri mineral türüne göre değişmektedir (Schweizer vd., 2021). Organik bileşikler mineral yüzeyine adsorbe olabileceği gibi Fe veya Al ile birlikte çökelebilir. Birlikte çökelme, organik karbonun oluşan mineral yapıya veya düzensiz yüzeylere dâhil olmasına katkı sağlayabilir. Sphagnum sulak alanlarında yapılan geniş ölçekli bir karşılaştırmada, bitkinin asidik ve fenolik ürünleri ile reaktif Fe–Al fazlarındaki artış arasında ilişki kurulmuş; metal bağlı karbonun MAOC birikimiyle ilişkili olduğu bildirilmiştir (Zhao vd., 2023). Bu nedenle toplam Fe miktarı yerine Fe fazının kristallenme derecesi, yüzey reaktivitesi ve organik maddeyle birlikteliği değerlendirilmelidir

Pirofosfatla özütlenen Fe_p ve Al_p, organik bileşiklerle kompleksleşmiş metal fraksiyonları için yöntemsel göstergelerdir. Pirofosfat bazı inorganik fazları da etkileyebilmektedir. Bu nedenle söz konusu fraksiyonlar, belirli bir bağ türünün doğrudan ölçümü olarak değerlendirilmemelidir. Seçici özütleme sonuçları mineralojik ve spektroskopik yöntemlerle desteklenmelidir (Parfitt & Childs, 1988).

Toprak nemi, redoks koşulları üzerinden Fe aracılı karbon stabilizasyonunu etkileyebilmektedir. Orta düzeyde nem; bitki üretimini, mikrobiyal dönüşümü ve MAOC öncüllerinin oluşumunu destekleyebilir. Suya doygunluk ise oksijen difüzyonunu sınırlandırır; Fe(III)'ün indirgenmesi Fe oksitlerini çözebilir ve ilişkili karbonu hareketlendirebilir. Drenaj sonrasında Fe(II)'nin yeniden yükseltgenmesi yeni reaktif yüzeyler oluşturabilir; organik karbon bu yüzeylerde tutulabilir veya Fe ile birlikte çökelebilir. Bu nedenle değişken su tablasına sahip taban topraklarında Fe–karbon ilişkisi mevsimsel olarak değişebilmektedir (Giannetta vd., 2022; Jia vd., 2024).

Redoks salınımlarının net etkisi süreçlerin zamanlamasına bağlıdır. İndirgenme sırasında Fe ile birlikte çözünen karbon gözenek suyunda kalabilir, mikrobiyal olarak kullanılabilir veya yanal akışla taşınabilir. Yeniden yükseltgenme hızlı gerçekleşirse yeni oluşan Fe fazları bu karbonun bir bölümünü tekrar tutabilir. Karbon sistemden uzaklaşmışsa aynı mineral yenilenmesi net bir stabilizasyon sağlamayabilir. Al fazları Fe gibi redoks tepkimesi göstermese de pH ve kompleksleşme koşullarındaki değişimlerden etkilenmektedir. Bu farklılık, Fe ve Al fraksiyonlarının ayrı değerlendirilmesini gerekli kılmaktadır (Giannetta vd., 2022; Jia vd., 2024).

pH; mineral yüzey yükünü, Al çözünürlüğünü ve mikrobiyal etkinliği etkilemektedir. Kil içeriği ise mineral yüzey alanını ve su tutma kapasitesini artırabilmektedir. Ancak kil yüzdesi tek başına MAOC kapasitesini açıklamaz; kil minerali türü, Fe–Al kaplamaları, özgül yüzey alanı ve mevcut karbon doygunluğu da dikkate alınmalıdır (Jia vd., 2024; Kleber vd., 2021). Topoğrafik konum ile tekstür birlikte değişebildiğinden istatistiksel modellerde bu etkilerin ayrıştırılması gerekmektedir.

3.6 Mekanistik sentez ve bilgi boşlukları

Literatür, topoğrafik etkilerin ardışık ve karşılıklı etkileşimli süreçler üzerinden ortaya çıktığına işaret etmektedir. Topoğrafya mikroiklim ve hidrolojiyle birlikte değişmekte; bu koşullar erozyon, birikme, agregat yapısı ve mineral reaktivitesini etkileyebilmektedir. Söz konusu süreçler POC–MAOC dağılımına ve karbonun kalıcılığına katkıda bulunmaktadır. Bununla birlikte ilişkiler doğrusal olmamakla birlikte bitki örtüsü, ana materyal, toprak yaşı ile arazi kullanımı tarafından değiştirilebilmektedir (Che vd., 2021; Dalzell vd., 2022; Giannetta vd., 2022).

Tepe konumlarında iyi drenaj ve sınırlı yukarı yamaç katkısı baskın olabilmektedir. Bitkisel girdiler yüzeyde POC oluşumunu desteklerken erozyon, POC'u ve ince mineral parçacıkları sistemden uzaklaştırabilir. Mineral yüzeylerin karbonla düşük doygunluğu yeni MAOC oluşumu için kapasite sağlayabilse de düşük nem veya sınırlı mikrobiyal dönüşüm bu kapasitenin kullanılmasını kısıtlayabilir.

Bu nedenle tepe konumundaki düşük toplam TOK yalnızca hızlı ayrışmayla açıklanmamalıdır (Che vd., 2021; Feyissa vd., 2023).

Yamaç konumları taşınma, geçici depolanma ve yeniden aşınmanın birlikte gerçekleşebildiği geçiş alanlarıdır. Agregatların taşınma sırasında parçalanması POC'u ayrışmaya açabilir; ince mineral parçacıklarla temas ise çözünmüş ve mikrobiyal kökenli karbonun tutulmasına katkı sağlayabilir. Net sonuç eğim uzunluğuna, yüzey örtüsüne, akışın sürekliliğine ve sedimanın arazide kalma süresine bağlıdır. Bu nedenle yamaç ortasındaki tek bir örnekleme noktası dinamik yamaç süreçlerini yeterince temsil etmeyebilir (Dalzell vd., 2022).

Taban konumlarında sediman birikimi, POC'un gömülmesine ve MAOC taşıyan ince fraksiyonların yoğunlaşmasına katkı sağlayabilir. Yüksek nem, oksijen kısıtı yoluyla mineralizasyonu yavaşlatabilir; ancak uzun süreli suya doygunluk Fe oksitlerinin indirgen çözünmesini ve ilişkili karbonun hareketlenmesini artırabilir. Dönemsel kuruma ise yeni Fe fazlarının oluş masına ve karbonun yeniden tutulmasına olanak verebilir. Bu nedenle taban konumlarının karbon sekestrasyon potansiyeli, yalnızca depolanan karbon miktarına değil; birikme, ayrışma, çözünme ve dışa taşınma akılarının dengesine bağlıdır (Giannetta vd., 2022; Jia vd., 2024).

Başlıca bilgi boşluğu, POC–MAOC fraksiyonları ile agregat sınıflarının aynı topoğrafik dizi üzerinde birlikte incelendiği çalışmaların azlığıdır. Benzer biçimde Fe_d–Fe_o–Fe_p, Al_d– Al_o–Al_p ve sürekli nem–redoks verileri çoğu çalışmada bütünleştirilmemektedir. Tek zamanlı örnekleme; kar erimesi, yaz kuraklığı ve değişken su tablasının etkilerini açıklamakta yetersiz kalmaktadır. Yüzey toprağına dayalı çalışmalar, derin horizonlardaki mineral koruma kapasitesini gözden kaçırabilir. Birikim alanındaki yüksek TOK değeri ise yerinde stabilizasyon ile yukarı yamaçtan taşınan karbonun ayrılmasına tek başına olanak vermeyebilir. Bir karst yamaç çalışmasında, yamaç konumu boyunca partikül organik madde (POM), mineral ilişkili organik madde (MAOM), mikrobiyal nekrokütle, lignin belirteçleri ve değişebilir Fe birlikte değerlendirilmiştir; ancak benzer bütünleşik tasarımlar yüksek dağ sistemlerinde hâlen sınırlıdır. Gelecek çalışmalarda profil ve yamaç ölçeğinde karbon kütle dengelerinin kurulması gerekmektedir (Wang vd., 2022; Zou vd., 2026).

3.7 İncelenen Çalışmaların Genel Özellikleri ve Temel Bulguları

Tablo 1, değerlendirmeye alınan çalışmaların genel özelliklerini ve temel bulgularını karşılaştırmalı olarak göstermektedir. Derleme, meta-analiz ve yöntem makalelerinde tek bir çalışma alanı veya standart örnekleme derinliği bulunmadığından ilgili hücrelerde bu durum belirtilmiştir. Bulgular, kaynaklarda incelenen koşullar ve raporlanan ilişkilerle sınırlandırılmıştır

Tablo 1: İncelenen Çalışmaların Genel Özellikleri ve Temel Bulguları

Çalışma Alanı / Ekosistem	Topoğrafik Faktör	Toprak Derinliği	Karbon Fraksiyonu	Diğer Temel Parametreler	Temel Bulgu	Kaynak ve Yıl
Kuzeybatı İngiltere tarımsal çayırları	–	0–10 cm (0–5 ve 5–10 cm; ayrıca 10–20 cm)	Mikrobiyal nekrokütle ve MAOM	13C/15N, mikrobiyal biyokütle, ince mineral fraksiyonu	İşaretli nekrotik C'nin yaklaşık üçte ikisi üç içinde mineral fraksiyonla ilişkilense de mineral ilişkili C sekiz ay içinde azalmıştır.	Buckeridge vd. 2022
Alpin çayır toprağı	Yükselti, bakı	A ve B horizonları	TOK ve Al/Fe ilişkili C	pH, Fe/Al seçici özütlemeleri, bitki ve iklim değişkenleri	İncelenen gradyanda yükselti ve bakı, Al–Fe fazlarıyla ilişkili TOK dağılımındaki farklılıklarla ilişkilendirilmiştir.	Che vd. 2021
Yağışlı tarım arazileri	TWI ve diğer DEM türevleri	0–10 cm	TOK	Sentinel-2, rastgele orman, destek vektör regresyonu, nem verileri	TWI çoğu modelde önemli bir değişken olmuş; çalışma	Cutting vd. 2024

					alanında TOK ile negatif ilişki göstermiştir.	
Erozyona açık tarımsal peyzaj	Yamaç konumu, erozyon, birikme	0-150 cm	TOK	DEM, arazi kullanımı, sediment yeniden dağılımı	Topoğrafya ve arazi kullanımı TOK tahminine katkı sağlamış; aşağı yamaçta birikmesi karbonun kısmen korunmasıyla ilişkilendirilmiştir.	Dalzell vd. 2022
Güneybatı Çin alpin orman ve çayırları	Yükselti	0–10 ve 10–20 cm	TOK ve stabilizasyon göstergeleri	Bitki örtüsü, iklim, toprak özellikleri	Karbon miktarı ve potansiyel stabilizasyon mekanizmaları yükselti ve ekosistem tipine göre farklılaşmıştır.	Feyissa vd. 2023
Ilıman hidromorfik ve çeltik toprakları	Hidrolojik konum, redoks rejimi	Elüviyal üst horizon ve illüviyal alt horizon	TOK ve Fe ilişkili C	Fe türleşmesi, X-ışını soğurma spektroskopisi, mikroagregatlar, redoks	Redoks çevrimleri Fe dönüşümleri ve mikroagregat içi/dışı C dağılımındaki değişimlerle ilişkilendirilmiştir.	Giannetta vd. 2022
Oregon Coast Range, ormanlı erozyon peyzajı	Erozyon hızı, tepe konveksliği	0-140 cm	TOK, POC ve MAOC	Δ14C, tekstür, toprak kalınlığı, ışık algılama ve uzaklık ölçme	İncelenen 16 alanda modellenen erozyon hızı arttıkça toplam TOK ve MAOC stokları üstel olarak azalmıştır.	Hunter vd. 2024

Zou vd. 2026

4. SONUÇ ve ÖNERİLER

İncelenen literatür, topoğrafyanın yüksek dağ topraklarındaki TOK dağılımını tek başına belirleyen bir değişken olmadığını; mikroiklim, hidroloji ve yanal materyal taşınımı aracılığıyla etkili olduğunu göstermektedir. Eğim erozyon ve birikme süreçleriyle, bakı enerji ve nem dengesiyle, yükselti sıcaklık ve bitki gelişme dönemiyle, topoğrafik pozisyon ise kaynak–alıcı ilişkileriyle bağlantılıdır. Bununla birlikte bu ilişkiler doğrudan POC veya MAOC değişiminin kanıtı değildir; agregat yapısı, tekstür, mineral yüzey özellikleri ve redoks koşulları temel aracı değişkenlerdir.

POC güncel bitkisel girdilere ve fiziksel bozulmaya görece hızlı yanıt verirken agregat oluşumu ve mikrobiyal dönüşüm süreçlerine de katkı sağlamaktadır. MAOC çoğunlukla daha uzun dönüş süreleriyle ilişkilendirilse de mineral ilişki kalıcılığı garanti etmemektedir. Özellikle indirgen koşullarda Fe oksitlerinin çözünmesi, desorpsiyon ve kök kaynaklı bileşikler mineral ilişkili karbonu yeniden hareketlendirebilir. Benzer biçimde taban konumlarındaki POC gömülmesi ve ince mineral birikimi karbon stokunu artırabilir; ancak yüksek stok, uzun süreli stabilizasyon veya net sekestrasyonla eşdeğer değildir.

Mevcut kanıtların önemli bir bölümü yüzey toprağına ve tek zamanlı örneklemeye dayandığından, topoğrafik konumların uzun süreli karbon dengesi üzerindeki etkisi belirsizliğini korumaktadır. Gelecekteki çalışmalarda yüzey ve derin horizonlardaki toplam TOK, serbest ve agregat içi POC, MAOC, MWD/GMD, tekstür, hacim ağırlığı ve taşlılık birlikte değerlendirilmelidir. Fed, Feo, Fep, Ald, Alo ve Alp fraksiyonları pH ve kil minerolojisiyle birlikte yorumlanmalı; sürekli nem, sıcaklık, redoks potansiyeli ve su tablası ölçümleri tek zamanlı örneklemeyi tamamlamalıdır. Erozyon ve birikme akılarının karbon bütçesine dâhil edilmesi, yüksek karbon içeriği ile uzun süreli karbon stabilizasyonunun birbirinden ayrılmasına katkı sağlayacaktır.

Abstract
Soil erosion is a major land-degradation process that threatens the sustainability of soil resources and reduces land productivity. In this study, the ICONA erosion-risk model was applied within a Geographic Information Systems (GIS) environment to determine the spatial distribution of erosion risk in Bayburt Province. Slope, geology, land use, and land cover, which are key factors influencing erosion processes, were evaluated within the model framework. Slope values derived from a Digital Elevation Model were classified into five classes, while geological units were categorized according to their lithological characteristics and susceptibility to erosion. Slope and geology were integrated using the ICONA evaluation matrix to generate the potential erosion map. Based on CORINE land-cover classes, vegetation cover was grouped into four density classes (<25%, 25-50%, 50-75%, and >75%). Land-use classes were adapted to the categories defined in the ICONA model and evaluated together with vegetation cover to generate the soil-protection map. The potential erosion and soil-protection layers were then integrated using the ICONA matrix to produce the final erosion-risk map. The results showed that 11.25% of the study area was classified as very low risk, 17.40% as low risk, 23.13% as moderate risk, 32.50% as high risk, and 15.72% as very high risk. High and very high risk areas together accounted for 48.22% of the study area, indicating that nearly half of the province is susceptible to erosion. The findings highlight the need to incorporate erosion susceptibility into land-use planning and to develop appropriate soil-conservation practices, particularly in high-risk areas. Integrating the ICONA model with GIS provides a practical approach for spatial erosion-risk assessment and for identifying priority areas for soil conservation and sustainable land management.
Keywords: ICONA, soil erosion, erosion risk, Geographic Information Systems, land use.

INTRODUCTION

Soil is a fundamental natural resource for sustaining agricultural production and maintaining ecosystem functions, and it plays a key role in sustainable environmental management (Doran & Parkin, 1994). Soil degradation is defined as the decline or loss of soil functions and is recognized as a major environmental problem threatening the sustainability of terrestrial ecosystems (Oldeman, 1997; Jie et al., 2002; Yücesoy & Edis, 2025).

Soil erosion is one of the major causes of soil degradation. The removal of topsoil rich in organic matter and nutrients reduces soil quality and fertility and consequently has adverse effects on agricultural production (Lal, 1998; García-Ruiz et al., 2015; Parlak et al., 2022). In addition, soil erosion negatively affects ecosystem integrity and biodiversity (Pimentel & Burgess, 2013; Asuoha et al., 2019; Firoozi & Firoozi, 2024). The fact that soil loss by erosion greatly exceeds the rate of soil formation through natural processes further emphasizes the severity of this problem (Verheijen et al., 2009).

Soil erosion is one of the major environmental problems in Türkiye. Approximately 86% of the country's soils are reported to be affected by erosion at varying degrees of severity, while 20.6% are classified as having moderate or higher erosion risk (Erpul et al., 2020). Türkiye's topographic structure,

climatic conditions, and inappropriate land-use practices are among the main factors that intensify erosion (Kılıç, 2022).

Because erosion results from the interaction of several environmental factors, spatial assessment methods are important for identifying erosion-prone areas. In this context, GIS-based erosion models are widely used not only to determine the spatial distribution of erosion risk but also to support the planning of soil management and conservation practices (Panagos et al., 2015). Among these models, ICONA enables the integration of key factors affecting erosion processes, including geology, slope, land use, and vegetation cover density, within a GIS environment (Everest et al., 2025). Owing to its limited data requirements and practical structure, the model can be used to identify the spatial distribution of erosion-susceptible areas (Yücesoy & Edis, 2025; Şeker et al., 2026). These characteristics make ICONA particularly suitable for erosion-risk assessment over large areas.

In this study, the ICONA model was implemented in a GIS environment to determine the spatial distribution of soil erosion risk within Bayburt Province. Slope, geology, land use, and land cover characteristics were evaluated together to reveal the spatial pattern of erosion risk. The main objectives were to determine the distribution of different erosion-risk classes across the province, identify areas with high and very high risk, and contribute to the identification of priority areas for soil conservation practices. The results are expected to provide a scientific basis for sustainable land management and soil conservation activities in Bayburt Province.

MATERIALS AND METHODS

General characteristics of the study area

Bayburt Province is located in the eastern part of the Black Sea Region of Türkiye and is bordered by Trabzon to the north, Erzincan to the south, Gümüşhane to the west, and Erzurum to the east. The study area covers the entire administrative boundary of Bayburt Province and has an area of approximately 371,136 ha. Elevation ranges from 1,390 to 3,357 m above sea level, with a mean elevation of approximately 1,550 m (Anonymous, 2026a). The mean annual precipitation of the province is 450.1 mm (Anonymous, 2026b). The location map of the study area is presented in Figure 1.

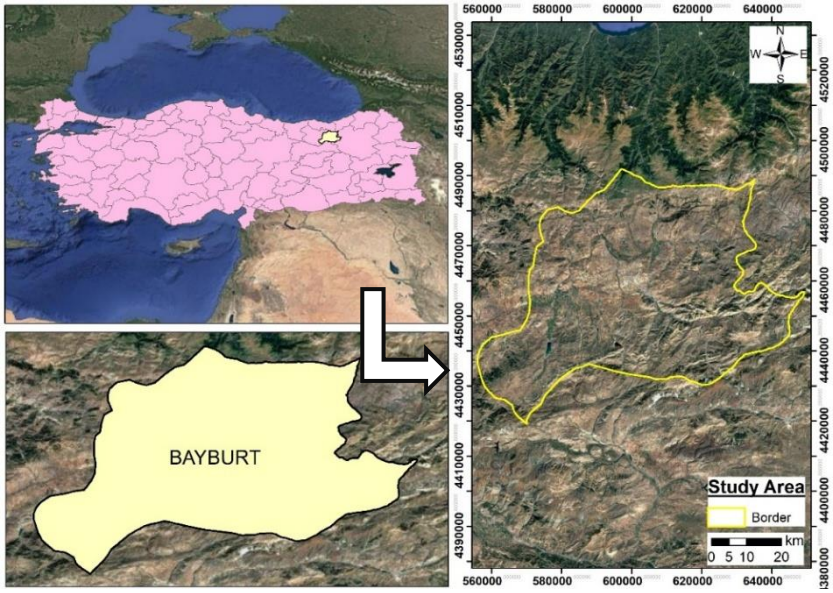

Figure 1. Location map of the study area

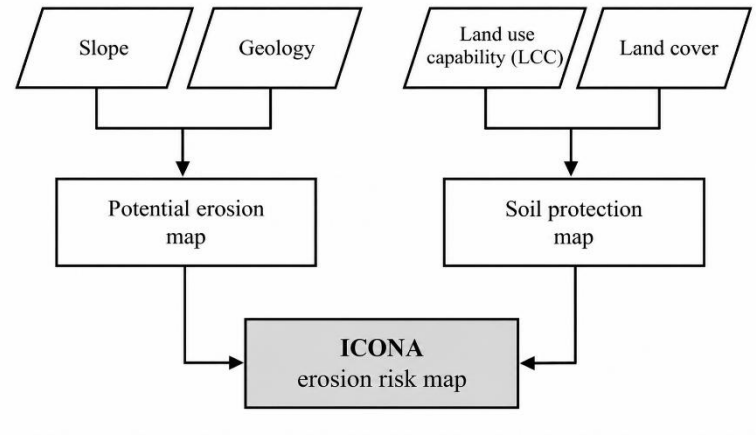
Slope, geology, land use capability (LCC), and land cover data were used as the primary input datasets for implementing the ICONA model. These datasets were processed in ArcGIS 10.8.2 to generate potential and actual erosion-risk maps. The methodological workflow and analysis stages followed in the study are presented in Figure 2.



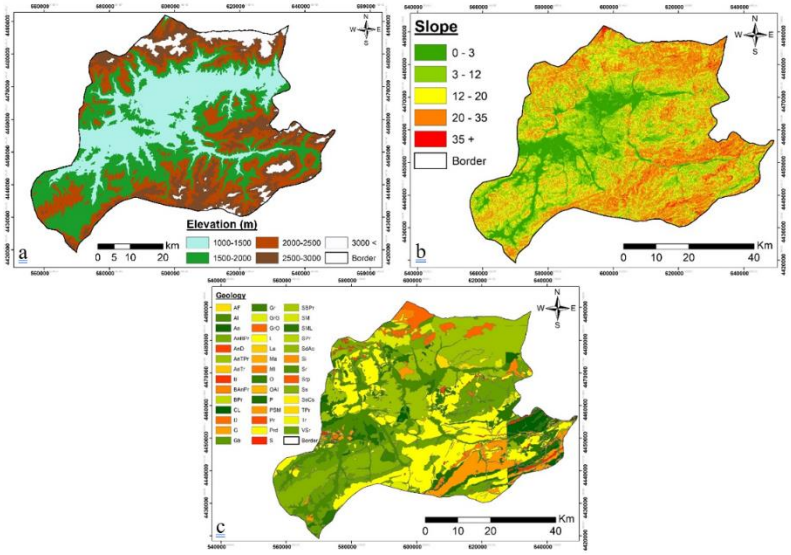


Figure 2. Workflow of the ICONA erosion model

RESULTS AND DISCUSSION

Bayburt Province has a highly rugged and mountainous topography. Elevation exceeds 2,000 m particularly in the northern and southern parts of the study area, while high and very high slope values occur across a substantial portion of the province (Figure 3a,b). This topographic setting is an important factor influencing surface runoff and erosion processes within the study area.

In terms of lithology, the study area is mainly characterized by limestone (22%), andesite (20%), volcanic-sedimentary rocks (15%), and conglomerate (8%) (Figure 3c). With respect to land use capability, Class VII and VIII lands are widely distributed throughout the study area. When considered together with the topographic and lithological characteristics, these features constitute important environmental factors controlling the spatial variation in erosion susceptibility.

The spatial distribution of land use capability classes shows that Class VII and VIII lands occupy extensive areas and are widely distributed across different parts of the study area. In contrast, Class I, II, and III lands occur in more limited and fragmented areas. Overall, lands with relatively high agricultural capability (Classes I-IV) are limited, whereas lands with greater land-use restrictions (Classes VI-VIII) are more widespread (Figure 4a). The rugged and mountainous topography of Bayburt, the extensive occurrence of steep slopes, its lithological characteristics, and the predominance of Class VII and VIII lands are therefore considered important factors influencing the spatial distribution of high erosion risk.

Figure 3. Elevation (a), slope (b), and geology (c) maps.

The areal distribution of land cover and land-use classes indicates that most of the study area consists of forest and semi-natural areas. This class accounts for 91.50% of the total area, whereas agricultural areas represent 6.59%. Artificial surfaces cover 1.70% of the study area, while water bodies have the smallest share at 0.21% (Figure 4b). These results show that natural and semi-natural land cover is clearly dominant, whereas agricultural and artificial land uses are more limited. Spatially, the land-cover classes display a fragmented and heterogeneous pattern across the study area (Figure 4b). The areal and proportional distribution of land-cover classes is presented in Table 1.

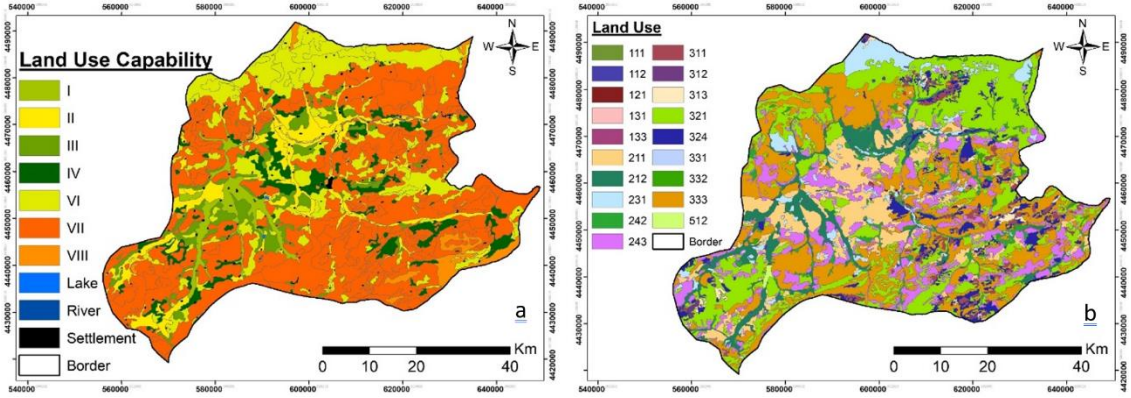

Figure 4. Land use capability (a) and land use (b) maps.

Table 1. Distribution of land-cover classes in the study area.

Land-cover classes	Area (ha)	Proportion (%)
1. Artificial surfaces	6,309.31	1.70
2. Agricultural areas	24,457.86	6.59
3. Forest and semi-natural areas	339,626.55	91.50
5. Water bodies	742.27	0.21
TOTAL	371,136.00	100.00

The vegetation cover-density classes indicate that most of the study area (90.96%) falls within the 50-75% cover class. Areas with 25-50% vegetation cover account for 4.63%, while areas with less than 25% cover represent 3.19%. Forest areas with the highest vegetation cover (>75%) constitute the smallest share, at 1.22% (Table 2). This distribution was considered an important component in determining the soil-protection level within the ICONA model.

Table 2. Distribution of vegetation cover-density classes in the study area.

Vegetation cover density	Cover type	Area (ha)	Vegetation cover (%)
<25%	Built-up, bare, or very sparsely vegetated areas	11,839.24	3.19
25-50%	Non-irrigated agricultural areas and rangelands	17,183.60	4.63
50-75%	Agricultural and natural areas expected to have more continuous/dense vegetation cover	337,636.19	90.96
>75%	Forest areas	4,527.86	1.22
	TOTAL	371,186.89	100.00

The potential erosion distribution obtained by jointly evaluating slope and geology is presented in Figure 5a, while the final ICONA erosion-risk map, generated after incorporating the soil-protection level, is shown in Figure 5b.

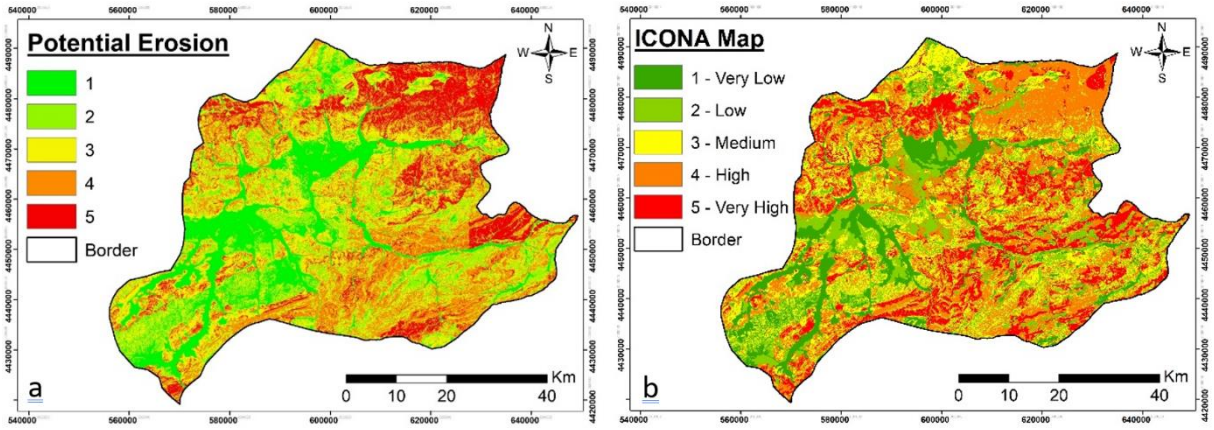

Figure 5. Potential erosion risk (a) and ICONA erosion-risk (b) maps.

The spatial distribution of erosion-risk classes according to the ICONA model shows that areas with high and very high erosion risk are concentrated particularly in the northern, northeastern, eastern, and southeastern parts of the study area, while they occur in a more fragmented pattern elsewhere. The general correspondence of these areas with steep and rugged terrain indicates that topography has an important influence on increasing erosion risk. In contrast, areas with very low and low erosion risk form broader and more continuous zones in the central and southwestern parts of the study area, which may be associated with the relatively gentler topographic conditions in these locations. The areal and proportional distributions of the ICONA erosion-risk classes are presented in Table 3. Şeker et al. (2026) evaluated erosion risk using the ICONA model in a micro-watershed in Rize and reported that high-risk areas were concentrated particularly where steep slopes, erosion-susceptible lithology, and sparse vegetation occurred. Dutal (2026) reported that areas with high and very high erosion susceptibility in Geben Valley National Park accounted for 29.17% and 48.88%, respectively.

Table 3. Areal and proportional distribution of ICONA erosion-risk classes

Class value	Erosion class	Area (ha)	Proportion (%)
1	Very Low	41,752.80	11.25
2	Low	64,577.66	17.40
3	Moderate	85,843.76	23.13
4	High	120,619.20	32.50
5	Very High	58,342.58	15.72
	TOTAL	371,136.00	100.00

The distribution of erosion-risk classes showed that 120,619.20 ha (32.50%) of the study area was classified as high risk and 58,342.58 ha (15.72%) as very high risk. Together, these two classes covered 178,961.78 ha (48.22%) of the study area. The moderate-risk class covered 85,843.76 ha (23.13%), whereas the low and very low risk classes together accounted for 106,330.46 ha (28.65%). These findings indicate that erosion risk is substantial across a considerable portion of the study area. Yücesoy and Edis (2025) reported that high and very high erosion-risk classes in the Terme Stream Watershed accounted for 32.2% and 35.6%, respectively. In a study conducted in the southwestern part of the Biga Peninsula using the ICONA model, Everest et al. (2025) classified 42.32% of the area as moderate risk, 21.82% as high risk, and 2.35% as very high risk. They also reported that high-risk areas were particularly associated with steep slopes and sparse vegetation cover.

CONCLUSION

In this study, the current status of soil erosion risk in Bayburt Province was evaluated using the ICONA model. The results showed that erosion risk varies considerably across the province and becomes pronounced in certain areas. In particular, the fact that high and very high risk classes together cover approximately half of the study area indicates that erosion is an important land-management issue in the region.

The distribution of high-risk areas indicates a close relationship between land characteristics and erosion risk. Therefore, erosion control should involve not only identifying existing risk but also developing

land-use practices compatible with the natural characteristics of the terrain. In high-risk areas, maintaining existing vegetation cover, adopting practices that reduce surface runoff and soil loss, and incorporating erosion risk into land-use decisions are particularly important.

The ICONA model enabled different land characteristics to be evaluated jointly within a GIS environment and facilitated the identification of priority areas for erosion control. The resulting maps can provide a useful basis for soil conservation and land-use planning in Bayburt. Future studies incorporating field observations and more detailed spatial datasets could further support model validation and contribute to more robust conservation decisions at the local scale.

FUNGAL DISEASES OF TOMATO (SOLANUM LYCOPERSİCUM L.): MAJOR PATHOGENS, SYMPTOMS AND MANAGEMENT STRATEGIES

DOMATESİN (SOLANUM LYCOPERSICUM L.) FUNGAL HASTALIKLARI: BAŞLICA PATOJENLER, BELİRTİLER VE MÜCADELE STRATEJİLERİ

Abstract
Tomato (*Solanum lycopersicum* L.) is the second most important vegetable crop worldwide after potato and is a key source of income and nutrition, particularly for smallholder farmers in tropical and subtropical regions. However, tomato production is severely constrained by a wide range of foliar, stem, fruit and soil-borne diseases caused mainly by fungal and fungal-like pathogens. Warm, humid and fluctuating climatic conditions favour the onset and rapid spread of these diseases, leading to substantial yield and quality losses and consequent economic damage. The most important diseases include seedling damping-off, Septoria leaf spot, early blight, late blight, anthracnose, powdery mildew, southern blight, Fusarium wilt, Verticillium wilt and buckeye rot. This review synthesizes current knowledge on these major tomato diseases, focusing on their causal agents, symptomatology and epidemiology, together with their agronomic and economic significance. For each disease, the main diagnostic symptoms and available management options are summarized, including cultural practices, use of resistant cultivars, seed and soil treatments, biological control and rational fungicide applications within an integrated disease management framework. By combining information from published literature and practical field experience, this review aims to provide a concise reference for researchers, extension specialists and growers seeking to improve sustainable disease management in tomato production systems
Keywords: Tomato, Fungal diseases, Control methods, IPM

Özet
Domates (*Solanum lycopersicum* L.), dünya genelinde patatesten sonra en önemli ikinci sebze ürünü olup özellikle tropikal ve subtropikal bölgelerdeki küçük ölçekli üreticiler için önemli bir gelir ve besin kaynağıdır. Bununla birlikte domates üretimi, başta fungal ve fungus benzeri patojenlerin neden olduğu yaprak, gövde, meyve ve toprak kökenli çok sayıda hastalık tarafından ciddi biçimde sınırlandırılmaktadır. Sıcak, nemli ve değişken iklim koşulları, bu hastalıkların ortaya çıkmasını ve hızla yayılmasını kolaylaştırarak önemli verim ve kalite kayıplarına, dolayısıyla ekonomik zararlara yol açmaktadır. Başlıca hastalıklar arasında fide çökerteni, Septorya yaprak lekesi, erken yanıklık, geç yanıklık antraknoz, külleme, güney yanıklığı, Fusarium solgunluğu, Verticillium solgunluğu ve meyvelerde görülen Phytophthora çürüklüğü yer almaktadır. Bu derlemede, domatesin söz konusu önemli hastalıklarına ilişkin güncel bilgiler; hastalık etmenleri, belirtileri ve epidemiyolojilerinin yanı sıra tarımsal ve ekonomik önemleri bakımından ele alınmaktadır. Her hastalık için tanıda kullanılan başlıca belirtiler ve mevcut mücadele seçenekleri özetlenmekte; kültürel uygulamalar, dayanıklı çeşit kullanımı, tohum ve toprak uygulamaları, biyolojik mücadele ve akılcı fungisit kullanımı entegre hastalık yönetimi çerçevesinde değerlendirilmektedir. Yayımlanmış literatürden elde edilen bilgiler ile uygulamaya yönelik saha deneyimlerini bir araya getiren bu derleme, domates üretim sistemlerinde sürdürülebilir hastalık yönetimini geliştirmeyi amaçlayan araştırmacılar, tarımsal yayım uzmanları ve üreticiler için özlü bir başvuru kaynağı sunmayı hedeflemektedir.
Anahtar kelimeler: Domates, fungal hastalıklar, mücadele yöntemleri, entegre mücadele.

GİRİŞ

Domates üretiminde hastalıkların etkisi yalnızca bitki ölümüyle sınırlı değildir. Yaprak alanının azalması fotosentetik kapasiteyi düşürürken, kök ve iletim dokularının zarar görmesi su ve besin maddesi alımını sınırlandırmaktadır. Meyve enfeksiyonları ise ürünün doğrudan pazarlanabilirliğini azaltmaktadır. Hastalık nedeniyle yaprak örtüsünü kaybeden bitkilerde meyvelerin güneş yanıklığına açık hale gelmesi, primer enfeksiyonların dolaylı kalite kayıpları da oluşturabileceğini göstermektedir (UC IPM, t.y., 2013c, 2013a, 2023).

Açık alan ve örtü altı yetiştiriciliğinde hastalık baskısı aynı değildir. Yağış ve sıçrayan suyla yayılan etmenler açık alanda öne çıkarken, seralarda uzun üretim dönemi, bitki yoğunluğu ve nem yönetimi önem kazanmaktadır. Toprakta kalıcı yapılar oluşturan patojenler ise ardışık yetiştiricilik dönemleri arasında inokulumun korunmasına neden olmaktadır. Bu nedenle farklı üretim bölgelerinde hazırlanmış mücadele programlarının yerel koşullara uyarlanmadan kullanılması uygun değildir (UC IPM, t.y., 2013h, 2013e, 2013l).

Funguslar ile oomyceteler arasında biyolojik ve taksonomik farklılıklar bulunmaktadır. *Alternaria, Septoria, Colletotrichum* ve *Fusarium* gerçek funguslar içerisinde yer alırken, *Phytophthora* ve *Pythium* geleneksel anlamda fungus benzeri organizmalar olarak adlandırılan oomycetelerdir (Kamoun ve ark., 2015). Bu ayrım, yalnızca terminolojik değildir; etmenlerin enfeksiyon biyolojisini ve mücadelede seçilecek aktif maddelerin etkinlik spektrumunu da ilgilendirir. Bütün domates hastalıklarını sıcak ve nemli koşullarla açıklamak da yetersizdir. Örneğin *Fusarium* solgunluğu ile Verticillium solgunluğu farklı sıcaklık eğilimleri gösterirken, külleme gelişimi uzun süreli serbest yaprak suyuna bağlı değildir (UC IPM, 2013h, 2013e, 2013l; FRAC, 2026).

Bu derlemenin amacı, seçilmiş önemli hastalıkların tanısı ile mücadele kararları arasındaki bağlantıyı ortaya koymak ve araştırıcılar, yayım uzmanları ve üreticiler için kullanılabilir bir başvuru metni sunmaktır. Hastalıklar; belirtileri sıralanan bağımsız sorunlar olarak değil, ortak inokulum kaynakları ve yetiştiricilik uygulamaları üzerinden etkileşen bir üretim sistemi içinde değerlendirilmiştir.

YÖNTEM

Çalışma, erişilebilir hakemli araştırmalar ile üniversitelerin bitki patolojisi ve entegre mücadele yayınlarının birlikte değerlendirildiği anlatısal bir derlemedir. Eylül 2026 itibarıyla doğrulanabilen kaynaklardan yararlanılmıştır. Tür adlarının açıklanmasında taksonomik araştırmalar, mücadele etkinliğinin tartışılmasında ise deneysel çalışmalar esas alınmıştır. Kurumsal yayım kaynakları, belirtilerin tanımlanması ve yetiştiricilik önlemlerinin açıklanmasında kullanılmıştır. Makale künyeleri ve DOI eşleşmeleri 11 Eylül 2026 tarihinde Crossref ve Europe PMC kayıtları üzerinden kontrol edilmiştir. Kurumsal kaynakların başlıkları ve güncelleme bilgileri ilgili resmî sayfalardan doğrulanmıştır. Çalışma bir sistematik derleme veya meta-analiz değildir; araştırmalar arasında birleşik etki büyüklüğü hesaplanmamıştır.

Ana kapsam, öz bölümünde belirtilen on hastalık grubudur. *Fusarium* kök ve kök boğazı çürüklüğü, solgunluk hastalığından ayrılması amacıyla ayrıca açıklanmıştır. Domateste görülen kurşuni küf, yaprak küfü, beyaz çürüklük ve diğer fungal hastalıklar bu kapsamın dışında bırakılmıştır. Farklı ülkelerdeki fungisit listeleri, Türkiye için ruhsatlı kullanım önerisi olarak aktarılmamıştır.

Başlıca hastalıklar

Fide çökerteni

Çökerten, tek bir etmenin oluşturduğu özgül bir hastalıktan çok, çıkış öncesi veya çıkış sonrası fide ölümlerini kapsayan bir hastalık grubudur. Domateste başlıca *Pythium* spp., *Phytophthora* spp. ve *Rhizoctonia* spp. ile ilişkilidir. Çıkış öncesinde tohum veya genç fide toprak altında çürür ve üretim alanında düzensiz çıkış görülür. Çıkış sonrasında ise gövdenin toprak seviyesinde koyulaşması, incelmesi ve dayanıklılığını kaybetmesi sonucunda fide devrilir (UC IPM, 2013b).

Yetersiz drenaj, sıkışmış veya aşırı ıslak yetiştirme ortamı enfeksiyon riskini artırmaktadır. Etmenlere göre sıcaklık gereksinimi değiştiğinden bütün çökerten vakaları yalnızca serin koşullara bağlanmamalıdır. Sağlıklı tohum ve fide, temiz viyol ve uygun yetiştirme ortamı kullanımı önceliklidir. Sulama, kök bölgesinde uzun süreli su doygunluğu oluşturmayacak şekilde düzenlenmelidir. Tohum uygulamalarının seçimi, saptanan etmenin fungus veya oomycete oluşuna göre yapılmalıdır. Fide kaybının önlenmesi, yeniden dikim maliyetinin ve üretim takvimindeki gecikmenin azaltılması bakımından önemlidir (UC IPM, 2013b, 2013i).

Septoria yaprak lekesi

Septoria lycopersici tarafından oluşturulan hastalık genellikle alt yapraklardan başlayarak üst yapraklara ilerlemektedir. Küçük, dairesel, açık kahverengi veya gri merkezli ve koyu kenarlı lekeler tipiktir. Lekelerin merkezinde görülen siyah noktacıklar, fungusun piknitleridir. Leke sayısı arttığında yapraklar sararır, nekroze olur ve işlevini kaybeder. Meyve enfeksiyonu seyrektir; başlıca ekonomik etki yaprak alanının azalması üzerinden ortaya çıkar (Meadows ve ark., 2021).

Etmen, bulaşık bitki artıkları ve bazı Solanaceae konukçuları üzerinde varlığını sürdürebilir. Yağmur sıçraması, ıslak yapraklarla temas eden işçiler ve ekipman sporların yayılmasına katkı sağlamaktadır. Yaprak ıslaklığının azaltılması, malçlama, bitkilerin desteklenmesi ve bulaşık artıkların yönetimi mücadeleyi destekler. Erken yanıklıkta görülen daha büyük ve belirgin halkalı lekelerden farklı olarak, *Septoria* lekeleri çoğunlukla küçük ve piknitlidir. Ancak karışık enfeksiyonlarda yalnızca leke görünümüne dayanmak yeterli olmayabilir. Koruyucu uygulamalar, sağlıklı yaprakların enfeksiyonunu sınırlandırmayı hedeflemeli; mevcut nekrozların iyileşmesi beklenmemelidir (Meadows ve ark., 2021).

Erken yanıklık

Domateste erken yanıklık, klasik kaynaklarda çoğunlukla *Alternaria solani* ile ilişkilendirilmiştir. Bununla birlikte büyük sporlu *Alternaria* türlerinin çok lokuslu değerlendirilmesi, domatesle ilişkili bazı etmenlerin *A. linariae* altında ele alınmasını sağlamıştır. *A. tomatophila* bu adın sinonimleri arasındadır. Eski kayıtların tamamının yeni bir ad altında otomatik olarak birleştirilmesi yerine, izolatların tanısında kullanılan yöntemlerin dikkate alınması gerekir (Woudenberg ve ark., 2014; Meadows ve ark., 2025).

Belirtiler çoğunlukla yaşlı yapraklarda başlayan kahverengi-siyah lekeler ve leke içindeki konsantrik halkalarla tanınmaktadır. Çevre dokuda sararma ve ilerleyen dönemde yaprak kaybı görülür. Meyvede, özellikle sap bağlantısı çevresinde koyu renkli, çökük ve derimsi lezyonlar gelişebilir. Etmen bulaşık artıklarda korunur; konidiler hava hareketleri ve sıçrayan suyla yayılır. Yaprak yüzeyindeki nem ve bitkinin fizyolojik durumu enfeksiyon gelişimini etkiler (Meadows ve ark., 2025; UC IPM, 2013c).

Mücadelede dengeli besleme, bitki artıklarının yönetimi, kendiliğinden çıkan domates ve patates bitkilerinin uzaklaştırılması, uygun münavebe ve yaprak ıslaklığını azaltan uygulamalar birlikte kullanılmalıdır. Çeşitler arasındaki duyarlılık farkları yararlı olmakla birlikte, tolerans ifadesi bağışıklık anlamına gelmez. Fungisit programı, hastalık riski ve yerel duyarlılık verileriyle ilişkilendirilmelidir. Ticari ürün adını değiştirmek, aktif maddeler aynı etki mekanizmasındaysa etkili bir direnç yönetimi sağlamaz (Meadows ve ark., 2025; UC IPM, 2013c; FRAC, 2026).

Geç yanıklık

Geç yanıklık, *Phytophthora infestans* tarafından oluşturulan ve uygun koşullarda hızla ilerleyen bir oomycete hastalığıdır. Yapraklarda başlangıçta suda haşlanmış görünümlü, düzensiz lekeler oluşur; bunlar kısa sürede genişleyerek kahverengi nekrozlara dönüşür. Nemli koşullarda yaprak alt yüzeyinde, lezyonun ilerleyen kenarında beyazımsı sporulasyon görülebilir. Yaprak sapı ve gövde enfeksiyonlarına, meyvede genellikle sertliğini başlangıçta koruyan kahverengi lezyonlar eşlik edebilir (UC IPM, 2013f). Yüksek nemin ılıman sıcaklıklarla uzun süre birlikte görülmesi epidemiyi desteklemektedir. Bulaşık fideler, çevredeki enfekteli konukçular ve hava yoluyla taşınan inokulum dikkate alınmalıdır. Geç yanıklığın yönetimi, hastalıksız fide kullanımı, çevredeki inokulum kaynaklarının azaltılması ve sık gözlemle başlamaktadır. Duyarlılığı daha düşük çeşitlerin kullanımı korumayı güçlendirebilir; ancak etmen popülasyonunun özellikleri önemlidir. Kimyasal koruma gerektiğinde oomycetelere etkili ve hedef kullanım için ruhsatlı ürünler seçilmeli, uygulama zamanı enfeksiyon riskiyle ilişkilendirilmelidir (UC IPM, 2013f; FRAC, 2026).

Antraknoz

Domates antraknozunun önemli etmenlerinden biri *Colletotrichum coccodes*'tir. Hastalık özellikle olgun ve aşırı olgun meyvelerde belirginleşmektedir. Dairesel, çökük lekeler zamanla genişler; yüzeyde koyu renkli yapılar ve nemli koşullarda somon renkli spor kitleleri görülebilir. Aynı etmen köklerde siyah noktacıklarla karakterize çürüklük oluşturabilmektedir. Dolayısıyla meyve enfeksiyonu ile kök kolonizasyonu aynı üretim alanında birlikte değerlendirilebilir (UC IPM, 2013a).

Meyve lekeleri, ürünün görünümünü ve depolama dayanıklılığını etkileyerek doğrudan ayıklama kaybına neden olur. Hasadın geciktirilmemesi, hastalıklı meyvelerin ayrılması ve meyvelerin ıslak toprakla temasının azaltılması yararlıdır. Olgunlaşma döneminde yağmurlama sulamanın sınırlandırılması ve Solanaceae dışındaki uygun bitkilerle münavebe inokulum yönetimini desteklemektedir. Hastalık baskısı ve yetiştirme koşulları değerlendirilmeden her üretim sistemi için zorunlu bir fungisit programı öngörülmemelidir (UC IPM, 2013a).

Külleme

Domateste külleme birden fazla etmenle ilişkilidir. *Leveillula taurica* enfeksiyonlarında yapraklarda düzensiz sarı alanlar ve ilerleyen dönemde nekroz görülmektedir. Beyaz sporulasyon, yaprakların alt veya üst yüzeyinde belirginleşebilir. Örtü altı üretiminde önemli olan ve yayım kaynaklarında *Oidium*

neolycopersici adıyla yer alan etmen ise yaprak yüzeyinde belirgin beyaz, unumsu koloniler oluşturmaktadır. Bu farklı görünümler nedeniyle bütün külleme enfeksiyonlarında aynı belirti dağılımı beklenmemelidir (UC IPM, 2023, 2013h).
Konidiler hava hareketleriyle yayılır. Külleme, uzun süreli serbest su gereksinimi bakımından birçok yaprak lekesi hastalığından ayrılır; yaprakların kuru görünmesi enfeksiyon riskinin olmadığı anlamına gelmez. Yaprak nekrozu ve işlev kaybı, meyvelerde güneş yanıklığı ve kalite azalmasına katkı sağlayabilir. Seralarda düzenli gözlem, dengeli bitki gelişimi ve uygun havalandırma temel önlemlerdir. Gerektiğinde erken dönemde uygulanan ruhsatlı fungisitler veya biyolojik ürünler programı destekleyebilir. Kükürt içeren ürünlerde sıcaklığa ve yağ uygulamalarıyla aralığa ilişkin etiket koşulları özellikle dikkate alınmalıdır (UC IPM, 2023, 2013h).

Fusarium solgunluğu
Fusarium solgunluğunun etmeni *Fusarium oxysporum* f. sp. *lycopersici*'dir. Köklerden giren etmen ksilemi kolonize eder. Alt yapraklarda sararma, bazen bitkinin yalnızca bir tarafında belirginleşen solgunluk ve gövde boyunca ilerleyebilen iletim demeti kahverengileşmesi tipiktir. Belirtiler, bitkinin su gereksiniminin arttığı meyve gelişimi döneminde daha belirgin hale gelebilir (UC IPM, 2013e).
Etmen toprakta uzun süre canlı kalabilmekte; bulaşık fide, toprak, ekipman ve bazı durumlarda tohumla taşınabilmektedir. Hastalık genellikle sıcak koşullarda öne çıkmaktadır. Mücadelede çeşidin yalnızca "*Fusarium* dayanıklı" olarak tanımlanması yeterli değildir. Konukçu dayanıklılığını aşma yeteneği bakımından tanımlanan üç temel ırka karşı çeşit veya anacın reaksiyonu ayrı değerlendirilmelidir. Belirli bir ırka dayanıklılık, diğer ırklara dayanıklılığı zorunlu kılmaz (UC IPM, 2013e; Stokes ve ark., 2026).
Dayanıklı çeşit veya anaç, temiz fide, bulaşık toprağın taşınmasının önlenmesi ve inokulum azaltıcı uygulamalar programın temelini oluşturmaktadır. McGovern'ın değerlendirmesi, fiziksel, biyolojik ve kimyasal yöntemlerin konukçu dayanıklılığıyla birlikte ele alınması gerektiğini ortaya koymaktadır (McGovern, 2015). Enfeksiyon geliştikten sonra yalnızca yapraktan yapılan bir uygulamayla kök ve iletim dokusu kolonizasyonunun ortadan kaldırılması beklenmemelidir.
Fusarium solgunluğu, *F. oxysporum* f. sp. *radicis-lycopersici* kaynaklı kök ve kök boğazı çürüklüğünden ayrılmalıdır. İkinci hastalıkta kök korteksinde çürüme ve kök boğazında lezyonlar daha belirgindir; iç dokudaki renk değişimi çoğunlukla gövdenin alt bölümünde yoğunlaşır. Serin toprak koşullarının hastalığı desteklemesi de ayırıcı epidemiyolojik bir özelliktir. Bununla birlikte kesin ayrım, belirti gözlemine ek olarak laboratuvar incelemesi gerektirebilir (McGovern, 2015; UC IPM, 2013d).

Verticillium solgunluğu
Verticillium dahliae, domateste Verticillium solgunluğunun önemli etmenidir. Alt yapraklarda kenardan içeri doğru daralan V biçimli sararma ve nekroz alanları görülebilir. Bitkiler gelişme geriliği gösterir; gövdenin özellikle alt kesimindeki iletim dokusunda açık kahverengi renk değişimi oluşabilir. *Fusarium* solgunluğuyla belirti benzerliği bulunduğundan, yalnızca renk tonu veya solmanın tek taraflılığı kesin tanı için kullanılmamalıdır (UC IPM, 2013l).
Etmen mikrosklerotlarıyla toprakta kalabilmekte ve geniş konukçu dizisi nedeniyle kısa münavebe programlarından sınırlı ölçüde etkilenebilmektedir. Hastalık, *Fusarium* solgunluğuna göre daha serin koşullarda öne çıkma eğilimindedir. Uygun dayanıklılığa sahip çeşit ve anaç seçimi ile bulaşık toprağın taşınmasının engellenmesi önemlidir. Dayanıklılığın ırka bağlı olduğu dikkate alınmalı; bir çeşitteki dayanıklılık özelliği bütün yerel izolatlara genellenmemelidir. Hastalık bitkileri öldürmeden de gelişmeyi ve pazarlanabilir verimi azaltabildiğinden, değerlendirme yalnızca ölüm oranına dayandırılmamalıdır (UC IPM, 2013l, 2013k).

Phytophthora meyve çürüklüğü
İngilizce literatürde "buckeye rot" olarak adlandırılan hastalık, domates meyvelerinde *Phytophthora* türlerinin oluşturduğu çürüklüktür. *P. parasitica* ve *P. capsici* bu hastalıkla ilişkilendirilen etmenler arasındadır. Toprakla temas eden veya toprak sıçramasına maruz kalan meyvelerde açık ve koyu kahverengi konsantrik bantlar görülebilir. Aynı etmen grubu köklerde çürüklük ve buna bağlı gelişme geriliği ile solmaya da neden olabilir (UC IPM, 2013g).
Topraktaki serbest su, kötü drenaj ve aşırı sulama enfeksiyon için önemlidir. Yükseltilmiş yetiştirme yatakları, drenajın iyileştirilmesi, meyvelerin toprakla temasının azaltılması ve sulamanın düzenlenmesi temel mücadele önlemleridir. Kök bölgesi ile meyve enfeksiyonu birlikte izlenmelidir. Toprak su yönetimindeki sorunu çözmeden yalnızca meyveye yönelik koruma uygulamak, inokulumun

sürekliliğini ortadan kaldırmaz. Kimyasal uygulama gerektiğinde hedef etmenin oomycete olduğu dikkate alınmalı ve ürünün ilgili hastalık için ruhsatı doğrulanmalıdır (UC IPM, 2013g; T.C. Tarım ve Orman Bakanlığı, t.y.).

Tablo 1. Seçilmiş domates hastalıklarında ön tanıyı destekleyen özellikler

Hastalık	Ön tanıda öne çıkan özellik	İlk yönetim önceliği
Çökerten	Çıkış kaybı veya toprak seviyesinden devrilme	Fide ve yetiştirme ortamı hijyeni
Septoria yaprak lekesi	Küçük, açık merkezli ve piknitli lekeler	Su sıçraması ve yaprak ıslaklığı
Erken yanıklık	Yaşlı yapraklarda halkalı nekrotik lekeler	Artık yönetimi ve bitki gelişimi
Geç yanıklık	Hızla genişleyen lekeler, nemde beyaz sporulasyon	Erken saptama ve risk döneminde koruma
Antraknoz	Olgun meyvede dairesel, çökük lekeler	Zamanında hasat ve meyve hijyeni
Külleme	Beyaz koloniler veya sarı alanlarla sporulasyon	Düzenli gözlem ve erken müdahale
Güney yanıklığı	Kök boğazında beyaz misel ve küresel sklerotlar	Bulaşık alan ve kök boğazı yönetimi
Fusarium solgunluğu	Solma ve gövde boyunca damar kahverengileşmesi	Irka uygun dayanıklılık ve temiz fide
Verticillium solgunluğu	V biçimli sararma ve gelişme geriliği	Dayanıklılık ve toprak taşınmasının önlenmesi
Phytophthora meyve çürüklüğü	Toprağa yakın meyvede kahverengi halkalı bantlar	Drenaj ve meyve toprak temasının azaltılması

Tablo, ilgili hastalık bölümlerinde belirtilen kaynaklardan sentezlenmiştir. Belirtiler tek başına kesin tanı için yeterli değildir.

Entegre hastalık yönetimi

Tanı ve üretim alanının izlenmesi

Mücadele kararının ilk aşaması, belirtilerin dağılımı ve gelişme hızının üretim koşullarıyla birlikte değerlendirilmesidir. Yalnızca tek bir yaprağın görüntüsü; kök çürüklüğü, iletim demeti enfeksiyonu veya karışık enfeksiyonun ayırt edilmesi için yeterli değildir. İnceleme, yaprakların iki yüzünü, gövde kesitini, kök boğazını, kökleri ve meyveleri kapsamalıdır. Aynı bitkide birden fazla etmenin bulunabileceği göz önünde tutulmalıdır (Meadows ve ark., 2021; UC IPM, 2013e, 2013l).

İzolasyon yapılabilen etmenlerde kültürel ve morfolojik incelemeler moleküler verilerle desteklenebilir. *Alternaria* türlerinin ayrımında çok lokuslu yaklaşımın sağladığı çözünürlük, yalnızca belirti veya tek bir karaktere dayalı tanının sınırlarını göstermektedir (Woudenberg ve ark., 2014). Tanı sonucunun yönetim açısından değeri, "fungus bulundu" ifadesinden daha ileri gitmesine bağlıdır. Özellikle solgunluk etmenlerinde tür, konukçu özelleşmesi ve gerektiğinde ırk bilgisinin, çeşit veya anaç seçiminde kullanılabilir olması gerekir (Stokes ve ark., 2026).

Sağlıklı üretim materyali ve kültürel önlemler

Mücadele programı dikimden önce başlamalıdır. Üretim alanının hastalık geçmişi, önceki ürünler ve drenaj durumu incelenmeli; fide kaynağı ile çeşit seçimi bu bilgilere göre belirlenmelidir. Hastalıkla bulaşık materyalin taşınmasını engelleyen ekipman temizliği, fide hijyeni ve alanlar arasındaki iş akışının düzenlenmesi, sonraki uygulamaların başarısını desteklemektedir (UC IPM, 2013i).

Kültürel önlemler, enfeksiyon sürecinin hangi aşamasını hedeflediğine göre seçilmelidir. Malç ve bitki destekleme, topraktan yaprağa veya meyveye sıçramayı azaltabilir. Havalandırma, yaprakların kuruma süresini etkileyebilir. Drenaj ve sulama kontrolü ise oomycete kök ve meyve enfeksiyonlarında doğrudan önem taşır. Buna karşılık iyi havalandırılan bir serada toprak kökenli solgunluk etmeni ortadan kalkmış olmaz. Önlemlerin etkisi, hedef etmenin biyolojisiyle açıklanmalıdır (Meadows ve ark., 2021; UC IPM, 2013h, 2013g).

Dayanıklı çeşitler ve aşılı fide

Dayanıklı çeşit veya anaç kullanımı, özellikle toprak kökenli hastalıklarda öncelikli seçeneklerden biridir. Bununla birlikte dayanıklılık değerlendirmesi; etmen, ırk, anaç ve kalem kombinasyonu ile üretim ortamını kapsamalıdır. Tohum veya fide etiketindeki dayanıklılık kodlarının ilgili etmenle eşleştirilmesi gerekir. Bir hastalığa dayanıklı anaç seçimi, diğer kök hastalıklarına karşı koruma sağlandığını göstermez (Stokes ve ark., 2026; UC IPM, 2013k).

El-Komy ve ark. (2026), solarizasyon, *Trichoderma asperellum* suş karışımı ve dayanıklı anaca aşılama uygulamalarını domates *Fusarium* solgunluğuna karşı tek başına ve kombinasyonlar halinde değerlendirmiştir. Üçlü uygulama, çalışmanın sera ve tarla koşullarında hastalığı baskılama bakımından öne çıkmıştır. Bu sonuç, farklı mekanizmaları birleştirmenin yararlı olabileceğine ilişkin deneysel kanıt sunmaktadır. Ancak kullanılan anaç, antagonist karışımı ve uygulama koşulları değiştirilerek aynı etkinliğin elde edileceği varsayılmamalıdır.

Tohum ve yetiştirme ortamı uygulamaları

Tohum koruma uygulamalarının temel hedefi, çimlenme ve erken fide döneminde enfeksiyon riskini azaltmaktır. Uygulamanın başarısı, hedef patojenin doğru belirlenmesine bağlıdır. Tek bir ürünün hem *Rhizoctonia* hem bütün oomycete etmenlere aynı ölçüde etkili olduğu kabul edilmemelidir. Uygun yetiştirme ortamı, kontrollü sulama ve hijyen, tohum uygulamasının tamamlayıcılarıdır (UC IPM, 2013b; FRAC, 2026).

Toprak veya substratın fiziksel yöntemlerle işlenmesi, başlangıç inokulumunu azaltmaya yöneliktir. Buhar uygulaması, özellikle kontrollü yetiştirme ortamlarında değerlendirilebilir. Solarizasyonun etkinliği ise toprakta oluşan sıcaklık ve uygulama koşullarıyla ilişkilidir. Bu yöntemler toprağın daha sonra yeniden bulaşmasını önlemez. Bu nedenle işlem sonrasında temiz fide, ekipman ve yetiştirme materyali kullanımı sürdürülmelidir. Fiziksel uygulamaların biyolojik mücadele ve dayanıklılıkla birleştirilmesi, tek yönteme bağımlılığı azaltabilecek bir seçenektir (McGovern, 2015; UC IPM, 2013d; El-Komy ve ark., 2026).

Biyolojik mücadele ve kanıtların yorumlanması

Domates hastalıklarına karşı biyolojik mücadelede *Trichoderma* ve *Bacillus* cinslerine ait suşlar önemli araştırma konularıdır. Antagonistik etkinlik; patojene doğrudan etki, kök çevresinde yerleşme ve bitkinin savunma yanıtlarının değişmesi gibi süreçlerle ilişkili olabilir. Ancak bir mikroorganizmanın tür adı, biyolojik etkinliğini tek başına açıklamaz. Suşun özellikleri, formülasyon, canlılık, uygulama yeri ve zamanlaması birlikte değerlendirilmelidir (Bandara ve Kang, 2024; Zhang ve ark., 2025; Xu ve ark., 2026).

Bandara ve Kang (2024), *T. virens* uygulama zamanının domates gelişimi ve rizosferin baskılayıcı özellikleri üzerindeki etkisini araştırmıştır. Dikim sırasında yapılan uygulama, incelenen koşullarda bitki gelişimi ve bazı baskılayıcılık ölçütleri bakımından öne çıkmıştır. Bununla birlikte çalışmada kullanılan rizosfer metabolitleri ve uçucu bileşik deneyleri, ticari tarlada gerçekleşecek hastalık kontrolüyle aynı ölçüt değildir. Bu ayrım, mekanizmayı destekleyen sonuçların doğrudan geniş ölçekli üretim önerisine dönüştürülmemesi gerektiğini göstermektedir.

Zhang ve ark. (2025), *Rhizophagus irregularis* ve *T. harzianum* uygulamalarının domates köklerinde *F. oxysporum* kolonizasyonunu azalttığını ve savunma hormonlarıyla ilişkili değişiklikler oluşturduğunu bildirmiştir. Ancak birlikte uygulama, tekli uygulamalara göre ilave baskılama sağlamamıştır. Bu bulgu, "daha fazla yararlı mikroorganizma daha yüksek koruma sağlar" varsayımının her kombinasyon için geçerli olmadığını ortaya koymaktadır. Mikrobiyal karışımların uyumluluğu ve katkısı deneysel olarak sınanmalıdır.

Xu ve ark. (2026) tarafından yürütülen çalışmada *B. velezensis* BV25, hem doğrudan antagonistik özellikler hem de sera koşullarında *Fusarium* solgunluğunu baskılayıcı etki göstermiştir. Savunmayla ilişkili enzim aktiviteleri ve genomik bulgular, olası mekanizmaları desteklemiştir. Bununla birlikte bir biyosentetik gen kümesinin saptanması, ilgili metabolitin her üretim koşulunda aynı düzeyde oluştuğunu kanıtlamaz. Laboratuvar inhibisyonu, sera hastalık şiddeti ve tarla verimi birbirinden farklı sonuç değişkenleridir.

Bu çalışmalar birlikte değerlendirildiğinde, biyolojik mücadele adaylarının seçimi için hastalık baskılama yanında kök bölgesinde kalıcılık, bitki gelişimi, uygulama maliyeti ve diğer üretim girdileriyle uyumluluğun da izlenmesi gerektiği sonucuna ulaşılmaktadır. *Fusarium*'a karşı alınan olumlu sonuçlar, *Septoria*, külleme veya geç yanıklığa doğrudan genellenmemelidir. Her hedef hastalık için uygulama yeri ve etkinliğin yeniden değerlendirilmesi gerekir.

Fungisitlerin rasyonel kullanımı

Fungisit seçimi, doğru tanıyı izlemelidir. FRAC sınıflandırması aktif maddeleri etki mekanizması ve direnç ilişkileri bakımından gruplandırmaktadır. Farklı ticari adlarla satılan ürünler aynı grupta yer alabileceğinden, yalnızca marka değişimi yeterli değildir. Programda ardışık uygulamalar, izin verilen uygulama sayısı ve karışım bileşenleri birlikte değerlendirilmelidir. Bütün hastalıklar için tek bir sabit ilaçlama aralığı önermek yerine, ürün etiketi ve hastalık riski esas alınmalıdır (FRAC, 2026).

Türkiye'de ürün seçimi yapılırken domates, hedef hastalık, yetiştirme biçimi ve uygulama yöntemi için güncel ruhsat ve etiket bilgileri Tarım ve Orman Bakanlığı Bitki Koruma Ürünleri Veri Tabanı üzerinden doğrulanmalıdır (T.C. Tarım ve Orman Bakanlığı, t.y.). Yabancı yayım kaynaklarındaki dozlar ve hasat öncesi bekleme süreleri Türkiye'ye doğrudan aktarılamaz. Derleme kapsamında belirli bir ticari ürün reçetesi yerine, uygulamanın hedefi ve direnç yönetimi ilkeleri değerlendirilmiştir.

Agronomik ve ekonomik değerlendirme

Bir mücadele yönteminin başarısı, yalnızca hastalık şiddetindeki azalma üzerinden belirlenmemelidir. Fide dönemindeki kayıplar yeniden dikim gereksinimi oluştururken, yaprak hastalıkları üretim süresini ve meyve kalitesini etkileyebilir. Meyve çürüklükleri doğrudan ayıklama kaybı yaratır. Solgunluk hastalıkları ise bitki canlılığını azaltarak hasat boyunca biriken kayıplara neden olabilir (UC IPM, 2013b, 2013a, 2013e, 2013l).

Üretim sistemi açısından karşılaştırma yapılırken pazarlanabilir verim, kalite sınıfları, fide veya anaç maliyeti, işçilik ve uygulama giderleri birlikte kaydedilmelidir. Hastalık baskısının düşük olduğu bir sezonda pahalı bir uygulamanın ekonomik getirisi sınırlı kalabilir; yüksek baskı altında ise aynı uygulama üretimin devamlılığını sağlayabilir. Bu nedenle farklı yıllar ve lokasyonlardan elde edilen veriler, tek sezonluk sonuçlara göre daha güçlü bir değerlendirme zemini oluşturur.

Sentezlenen bilgiler, ortak kültürel önlemlerin birden fazla hastalık için yarar sağlayabileceğini göstermektedir. Bununla birlikte her önlemin bütün etmenlerde eşdeğer etkisi bulunmamaktadır. Ekonomik karşılaştırmada, önlenen kayıpla uygulama maliyeti arasındaki ilişki kadar, yöntemin üretici tarafından düzenli uygulanabilirliği de dikkate alınmalıdır. Bu değerlendirme özellikle küçük işletmelerde ekipman, sağlıklı fideye erişim ve teknik bilgi gibi sınırlamalarla birlikte yapılmalıdır.

SONUÇ

Domateste fungal ve oomycete hastalıklarının sürdürülebilir yönetimi, başlangıç inokulumunun azaltılması ve enfeksiyon koşullarının sınırlandırılmasıyla başlamaktadır. Doğru tanı, hastalıksız fide ve yetiştirme materyali, etmen ve ırka uygun dayanıklılık, su yönetimi ve sanitasyon programın temel bileşenleridir. Biyolojik ve kimyasal uygulamalar, bu temeli güçlendirecek biçimde seçilmelidir.

Güncel çalışmalar, biyolojik mücadelede suş ve zamanlama etkilerinin önemli olduğunu; fiziksel uygulamalar, aşılama ve antagonistlerin bazı koşullarda birlikte yarar sağlayabildiğini göstermektedir. Buna karşılık her kombinasyon ek yarar üretmemektedir. Türkiye'de farklı yetiştirme sistemlerini temsil eden çok yıllı denemeler, yerel etmen ve ırk dağılımının belirlenmesi, fungisit duyarlılığının izlenmesi ve biyolojik ürünlerin pazarlanabilir verim üzerinden değerlendirilmesi öncelikli araştırma alanlarıdır. Üreticiye aktarılacak programlar, bu verilerle desteklenen ve uygulama sonucuna göre güncellenen programlar olmalıdır.

Abstract
Agricultural production faces increasingly significant challenges. Diseases caused by fungal pathogens lead to substantial economic losses worldwide by reducing crop yield and quality. Although conventional synthetic pesticides have long been widely used to control these pathogens, their continuous and intensive use has contributed to persistent problems, including environmental pollution, disruption of ecological balance, food safety risks, and pesticide residues. These adverse effects highlight the need to develop sustainable, environmentally friendly alternatives for disease management in agricultural production. Among approaches aimed at reducing reliance on chemical inputs, biological control using biocontrol agents stands out as a promising strategy for environmentally sustainable agriculture, owing to its potential to effectively suppress target pathogens.
In the present study, the biocontrol efficacy of selected *Trichoderma* spp., including *T. asperellum*, *T. harzianum*, *T. harnatum*, and a commercial *T. harzianum*-based product, obtained from different hosts and sources, was evaluated against *Fusarium avenaceum*, *F. citricola*, *F. acuminatum*, and *Monilinia laxa*. The antagonistic activity of the tested *Trichoderma* isolates was investigated against *Fusarium* species associated with disease development and yield losses in woody plants, as well as against *M. laxa*, an important fungal pathogen responsible for severe fruit rot, particularly in stone fruits. The antagonistic potential of the isolates was assessed under in vitro conditions using dual-culture and double-plate assays. In the dual-culture assays, the effects of the *Trichoderma* isolates on the radial mycelial growth of the target pathogens were evaluated, and their ability to inhibit pathogen growth was determined. Double-plate assays were additionally performed to investigate the potential contribution of volatile or diffusible antifungal compounds to the antagonistic interactions.
The results demonstrated that *T. harzianum* isolated from the nut rhizosphere exhibited strong antagonistic activity, significantly inhibiting the mycelial growth of *F. acuminatum*. Furthermore, the *T. asperellum* isolate obtained from the apple rhizosphere and the commercial *T. harzianum*-based product showed high efficacy against *Monilinia laxa*, indicating their potential as promising biological control agents against this important fruit pathogen.
Keywords: Antogonistic activity, in vitro, mycoparasitic fungus

Özet
Tarımsal üretimde fungal patojenlerin neden olduğu hastalıklar, ürün verimi ve kalitesinde küresel ölçekte ciddi ekonomik kayıplara yol açmaktadır. Bu patojenlerle mücadelede uzun yıllardır konvansiyonel sentetik pestisitler yaygın olarak kullanılsa da, bu kimyasalların sürekli ve yoğun kullanımı çevre kirliliği, ekolojik dengenin bozulması, gıda güvenliği riskleri ve kalıntı problemleri gibi kronik sorunları beraberinde getirmiştir. Bu olumsuzluklar, tarımsal üretimde sürdürülebilir, çevre dostu ve alternatif hastalık yönetim stratejilerinin geliştirilmesini zorunlu kılmaktadır. Kimyasal girdilere olan bağımlılığı azaltmayı hedefleyen yaklaşımlar arasında, biyo-ajanların kullanımıyla şekillenen biyolojik

mücadele, hedef patojenleri etkili bir şekilde baskılama potansiyeliyle çevre dostu tarım modellemelerinde güçlü bir alternatif olarak öne çıkmaktadır. Bu çalışmada, farklı konukçu ve kaynaklardan elde edilen *Trichoderma* spp. izolatlarının; *T. asperellum, T. harzianum, T. harnatum* ve ticari *T. harzianum* esaslı bir ürünün, *Fusarium avenaceum, F. citricola, F. acuminatum* ve *Monilinia laxa*'ya karşı biyolojik mücadele etkinliğinin belirlenmesi amaçlanmıştır. Test edilen *Trichoderma* izolatlarının, odunsu bitkilerde hastalık gelişimi ve verim kayıplarıyla ilişkili *Fusarium* türleri ile özellikle sert çekirdekli meyvelerde önemli bir hastalık etmeni olan ve ciddi meyve çürüklüklerine neden olan *M. laxa* üzerindeki antagonistik aktiviteleri in vitro koşullarda değerlendirilmiştir. İzolatların antagonistik potansiyeli, ikili kültür ve çift petri (double-plate) testleri kullanılarak belirlenmiştir. İkili kültür testlerinde, *Trichoderma* izolatlarının test edilen patojenlerin radyal misel gelişimi üzerindeki etkileri değerlendirilmiş ve patojen gelişimini engelleme düzeyleri belirlenmiştir. Ayrıca, antagonistik etkileşimlerde uçucu veya difüze olabilen antifungal bileşiklerin olası katkısını araştırmak amacıyla çift petri testleri gerçekleştirilmiştir.
Elde edilen sonuçlar, ceviz rizosferinden izole edilen *T. harzianum* izolatının güçlü antagonistik aktivite gösterdiğini ve *F. acuminatum*'un misel gelişimini önemli ölçüde engellediğini ortaya koymuştur. Ayrıca, elma rizosferinden elde edilen *T. asperellum* izolatı ile ticari *T. harzianum* esaslı ürünün *Monilinia laxa*'ya karşı yüksek etkinlik gösterdiği ve bu nedenle söz konusu önemli meyve patojenine karşı umut vadeden biyolojik mücadele ajanları olabileceği belirlenmiştir.
Anahtar kelimeler: Antagonistik aktivite, in vitro, mikoparazitik fungus

INTRODUCTION

The genus *Fusarium* comprises a diverse group of filamentous ascomycetous fungi that are widely distributed in agricultural and natural ecosystems and includes numerous economically important plant pathogens. Members of the genus are associated with a broad range of diseases affecting cereals, legumes, vegetables, fruit crops, ornamentals, and forest plants, causing root rot, crown rot, stem and fruit diseases, vascular wilts, and seedling diseases. The importance of *Fusarium* extends beyond direct crop losses because several species are also capable of producing mycotoxins that pose significant risks to food and feed safety (Dean et al., 2012; Ma et al., 2013; Munkvold et al., 2021).
Stone fruit production is significantly affected by *Monilinia laxa*, a destructive fungal pathogen associated with brown rot, blossom blight, and spur infections (Uysal, 2024).

MATERIALS AND METHODS

In this study, two phytopathogenic Fusarium isolates (*F. citricola*, *F. acuminatum*) and *T. asperellum, T. harzianum, T. harnatum* strain as biocontrol agents which had been previously characterised with molecular techniques were used in in vitro assays. The pathogens and antagonistic fungi were grown at 26 ± 1ºC for 7 days on potato dextrose agar (PDA). The fungal discs with a 5 mm diameter of 7-day-old fresh cultures were used in all experiments.

Dual Culture Assay

Dual culture tests were conducted according to the method proposed by (Rahman et al, 2009). Briefly, mycelium discs (5 mm) of *Fusarium* spp. and *Trichoderma* isolates were taken from the margins of 7-day-old cultures and placed at a distance of 3 cm in a PDA medium. Plates prepared by inoculating only pathogens were considered as a control group. All groups were incubated at 26 ± 1 ºC for 7 days.

Isolation of Fungi

For the isolation of the target fungal pathogens, symptomatic plant tissues showing root, crown, stem, or fruit rot were collected from the respective hosts. Samples were thoroughly washed under running tap water and blotted dry with sterile paper towels. Small tissue pieces were excised from the margins between healthy and necrotic tissues and surface-disinfested by immersing them in 0.1% sodium hypochlorite (NaOCl) for 1–3 min, depending on tissue tenderness. The disinfected tissues were rinsed with sterile distilled water and blotted dry. Small pieces approximately 2–3 mm in size were then aseptically transferred onto appropriate isolation media and incubated under suitable conditions. Emerging fungal colonies were subcultured onto fresh media and purified for subsequent morphological and molecular identification (Agrios, 2005).
Trichoderma isolates were obtained from the rhizosphere soil of the respective host plants, including apricot, hazelnut, apple, and strawberry. Rhizosphere soil samples were collected from the root zone of

the plants and processed for the isolation of *Trichoderma* spp. The recovered isolates were purified and maintained on appropriate culture media for subsequent morphological identification and antagonistic assays against the target fungal pathogens. The isolation of *Trichoderma* from rhizosphere soil was performed following commonly used procedures for the recovery of *Trichoderma* spp. from soil and plant-associated environments (Elad et al., 1981; Papavizas, 1985).

Molecular Identificatıon of The Fungi Used

Dna Extraction

The isolates were grown on potato dextrose agar (PDA) at 24°C for 10–12 days. Genomic DNA was extracted using the Qiagen DNeasy Blood & Tissue Kit (Qiagen, Madison, WI, USA) according to the manufacturer's protocol.

The internal transcribed spacer (ITS) region was amplified using the ITS1 and ITS4 primer pair for *Trichoderma* spp. and *Monilinia laxa* (White et al., 1990, Kroon et al. 2004). PCR amplification was performed with an initial denaturation at 94°C for 4 min, followed by 35 cycles of denaturation at 94°C for 60 s, annealing at 58°C for 60 s, and extension at 72°C for 60 s, followed by a final extension at 72°C for 5 min., The RPB2 region was amplified using the primer pair fRPB2-5F/fRPB2-7cR for *Fusarium* spp. (Liu et al., 1999). PCR amplification was performed with an initial denaturation at 95°C for 5 min, followed by 35 cycles of denaturation at 95°C for 1 min, annealing at 48°C for 2 min, a temperature increase of 0.2°C s^{-1} to 72°C, and extension at 72°C for 2 min, followed by a final extension at 72°C for 10 min (Table 1). PCR reactions were performed in a final volume of 50 µL, consisting of 5 µL of DNA template (approximately 10 ng), 26 µL of Thermo Scientific™ PCR Master Mix, 15 µL of nuclease-free water (Merck), and 2 µL of primers.

Agarose Gel Electrophoresis and PCR Product Selection

The PCR products were separated by electrophoresis on a 1.5% agarose gel prepared in 1× TAE buffer (40 mM Tris-acetate, 1 mM EDTA, pH 8.0). To prepare the agarose gel, 1.5 g of agarose was added to 100 mL of 1× TAE buffer in an Erlenmeyer flask and heated in a microwave oven until completely dissolved. After the solution had cooled to a suitable temperature, 5 µL of Nucleic Acid Gel Staining Solution (per 100 mL of gel) was added and thoroughly mixed. The molten agarose was then poured into a horizontal electrophoresis chamber fitted with an appropriate comb and allowed to solidify.

Following electrophoresis, the gel was visualized using a UV transilluminator imaging system. Isolates producing positive bands of the expected size corresponding to the target gene regions were identified, and the respective PCR products were submitted for sequencing.

The internal transcribed spacer (ITS) regions of ITS-4 and ITS-5, all *Trichoderma* spp and *Fusarium* spp. the all isolates were amplified and the obtained gene sequences were compared with the ones deposited in GenBank. All the fungi with the sequences deposited in GenBank.

Statistical analysis

The antagonistic activity of the *Trichoderma* isolates against the pathogen was evaluated using the dual-culture technique. The percentage inhibition of radial mycelial growth (PIRG) was calculated according to Skidmore and Dickinson (1976) using the following formula: PIRG (%) = [(C − T) / C] × 100, where C represents the radial growth of the pathogen in the control treatment and T represents the radial growth of the pathogen in the presence of the *Trichoderma* isolate. Each treatment was evaluated using two experimental replicates, and the mean radial growth and percentage inhibition values were calculated. Because only two replicates were available for each treatment, the results were evaluated using descriptive statistics, and no inferential statistical tests were performed.

Results and Discussion

Molecular identification of the fungal isolates

Molecular identification was performed using ITS sequences for the Trichoderma isolates and *Monilinia laxa*, whereas the RPB2 region was used for the identification of the Fusarium isolates. PCR amplification produced products of the expected sizes for the target regions, and positive amplification products were selected for sequencing. The obtained sequences were compared with sequences deposited in GenBank to support the identification of the fungal isolates.

The antagonistic activities of the tested Trichoderma isolates against the target Fusarium species were evaluated using the dual-culture assay. Differences were observed among the Trichoderma isolates in their ability to suppress the radial mycelial growth of the tested pathogens. The percentage inhibition of radial mycelial growth (PIRG) was calculated based on the radial growth of the pathogens in the control plates and in the presence of Trichoderma isolates.

The antagonistic activity of the tested *Trichoderma* isolates against *Fusarium acuminatum* varied among the isolates. The pathogen showed a mean radial growth of 53.0 mm in the control treatment, whereas the presence of *Trichoderma* isolates reduced pathogen growth to 23.0–30.0 mm. The highest inhibition rate was observed for T-5 (*Trichoderma harnatum*) isolated from strawberry, with 56.6% inhibition and a mean pathogen growth of 23.0 mm. This was followed by T-2 (*T. harzianum*) isolated from walnut, with 54.7% inhibition, and T-3 (*Trichoderma asperellum*) isolated from apple, with 51.9% inhibition. The T-4 *T. harzianum* isolate and T-1 *T. harzianum* isolate obtained from apricot showed 45.3% and 43.4% inhibition, respectively (Table 2) (Figure1). These results indicate that all tested *Trichoderma* isolates suppressed the mycelial growth of *F. acuminatum* compared with the pathogen control, with T-5 showing the highest observed antagonistic activity. The inhibitory effect may be associated with competition for nutrients and space, mycoparasitism, and the production of antifungal metabolites, which are among the mechanisms commonly reported for *Trichoderma* spp. (Elad et al., 1981; Papavizas, 1985).

Table 2. Antagonistic activity of Trichoderma isolates against Fusarium acuminatum based on dual-culture assay.

Isolate no	Isolate source	Pathogen fungal growth (mm)	Trichoderma growth (mm)	Inhibition of radial growth (%)	Growth differences (T - P) (mm)
T-1	Apricot- *T. harzianum*	30,00	63,50	**43,4%**	33,50
T-2	Walnut-*T. harzianum*	24,00	58,00	**54,7%**	34,00
T-3	Apple- *Trichoderma asperellum*	25,50	66,00	**51,9%**	40,50
T-4	*Trichoderma harzianum*	29,00	60,00	**45,3%**	31,00
T-5	Strawberry- *T. harnatum*	23,00	61,00	**56,6%**	38,00
Control	*Fusarium acuminatum*	53,00	0,00	**0,0%**	-

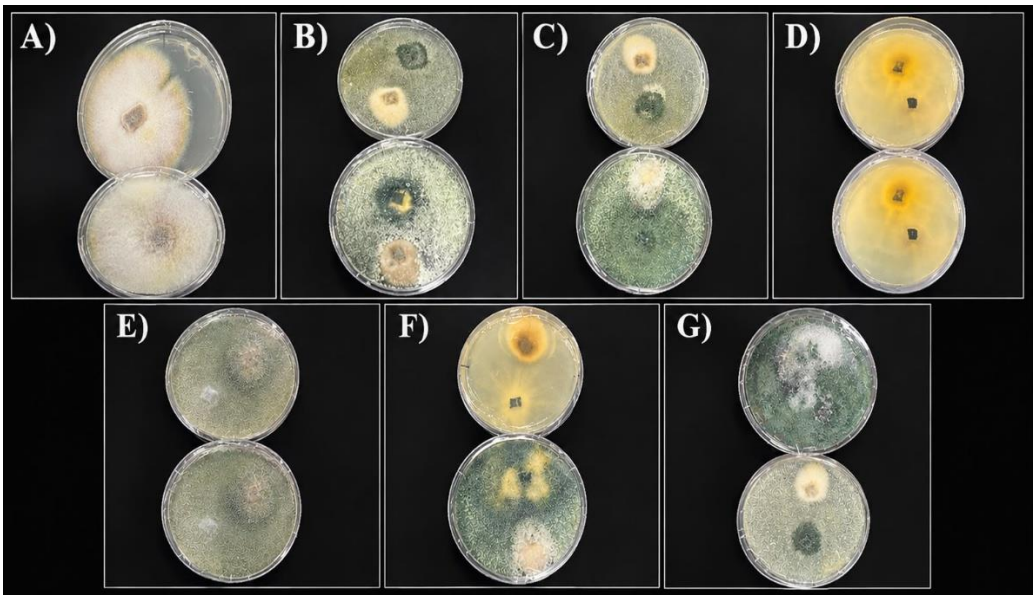

Figure 1. Dual-culture assays of different *Trichoderma* isolates against *Fusarium acuminatum*: A) *Fusarium acuminatum* control, B) *Trichoderma harzianum* isolate isolated from Walnut, C) *T. harzianum* commercial fertilizer product, D) *Trichoderma asperellum* isolated from apple , E) *Trichoderma harzianum* isolated from Strawberry , F) *Trichoderma harzianum* isolated from, G) Trichoderma harzianum Apricot

The growth of *Fusarium citricola* was markedly reduced in the presence of all tested *Trichoderma* isolates. Compared with 46.0 mm growth in the control, pathogen growth ranged from 12.5 to 18.0 mm in the dual-culture treatments. The greatest suppression was obtained with T-3 (*Trichoderma asperellum*) from apple and T-4 (*T. harzianum*), both providing 72.8% inhibition. T-2 (*T. harzianum*) from walnut also showed strong activity (70.7%), while T-5 (*Trichoderma harnatum*) and T-1 (*T. harzianum*) resulted in 62.0% and 60.9% inhibition, respectively (Table 3) (Figure2). The marked reduction in pathogen growth suggests a strong antagonistic interaction between the tested *Trichoderma* isolates and *F. citricola*. This activity may involve rapid colonization, competition, and antifungal metabolite production. As the experiment was based on two replicates, the findings are considered preliminary and should be validated in further studies.

Table 3. Antagonistic activity of Trichoderma isolates against Fusarium citricola based on dual-culture assay.

Isolate no	**Isolate source**	**Pathogen fungal growth (mm)**	**Trichoderma growth (mm)**	**Inhibition of radial growth (%)**	**Growth differences (T - P) (mm)**
T-1	Apricot- *T. harzianum*	18,00	71,50	**60,9%**	53,50
T-2	Walnut-*T. harzianum*	13,50	72,50	**70,7%**	59,00
T-3	Apple- *Trichoderma asperellum*	12,50	71,50	**72,8%**	59,00
T-4	*Trichoderma harzianum*	12,50	74,00	**72,8%**	61,50
T-5	Strawberry- *T. harnatum*	17,50	71,00	**62,0%**	53,50
Control	*Fusarium citricola*	46,00	0,00	**0,0%**	-

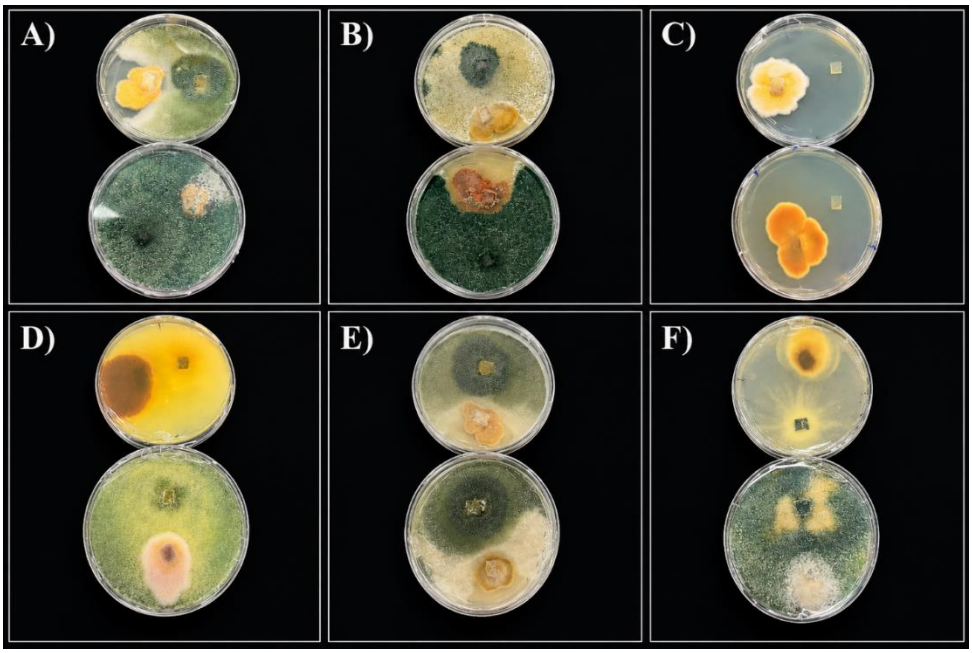

Figure 2. Dual-culture assays of different *Trichoderma* isolates against *Fusarium citricola*: A) *T. harzianum* commercial fertilizer product, B) *Trichoderma harzianum* isolate isolated from Walnut, C) *Fusarium citricola* control, D) *T. harzianum* commercial fertilizer product, E) *Trichoderma harzianum* isolated from Strawberry- T. F) *Trichoderma asperellum* isolated from Apple, G) *Trichoderma harzianum* commercial fertilizer product

The antagonistic activity of the tested *Trichoderma* isolates against *Monilinia laxa* varied among the treatments. The mean radial growth of *M. laxa* was 46.0 mm in the pathogen control, whereas the presence of *Trichoderma* isolates reduced pathogen growth to 12.5–18.0 mm. The highest inhibition was observed with the *Trichoderma asperellum* isolate obtained from the apple rhizosphere (T-3) and the commercial *T. harzianum*-based product (T-4), both showing a mean pathogen growth of 12.5 mm and 72.83% inhibition. These treatments were followed by the hazelnut-rhizosphere isolate (T-2) with 70.65% inhibition, while the strawberry (T-5) and apricot (T-1) isolates showed 61.96% and 60.87% inhibition, respectively (Table 4) (Figure 3). The strong inhibitory activity observed in T-3 and T-4 indicates their potential as biological control agents against *M. laxa*. The observed antagonism may be associated with competition for nutrients and space, mycoparasitism, and the production of antifungal metabolites, mechanisms commonly reported for *Trichoderma* spp. (Elad et al., 1981; Papavizas, 1985).

Table 4. Antagonistic activity of Trichoderma isolates against Monilia laxa based on dual-culture assay.

Isolate no	Isolate source	Pathogen fungal growth (mm)	Trichoderma growth (mm)	Inhibition of radial growth (%)	Growth differences (T - P) (mm)
T-1	Apricot- *T. harzianum*	18,00	71,50	**60,9%**	53,50
T-2	Walnut- *T. harzianum*	13,50	72,50	**70,7%**	59,00

Control	*Monilia laxa*	46,00	0,00	**0,0%**	-

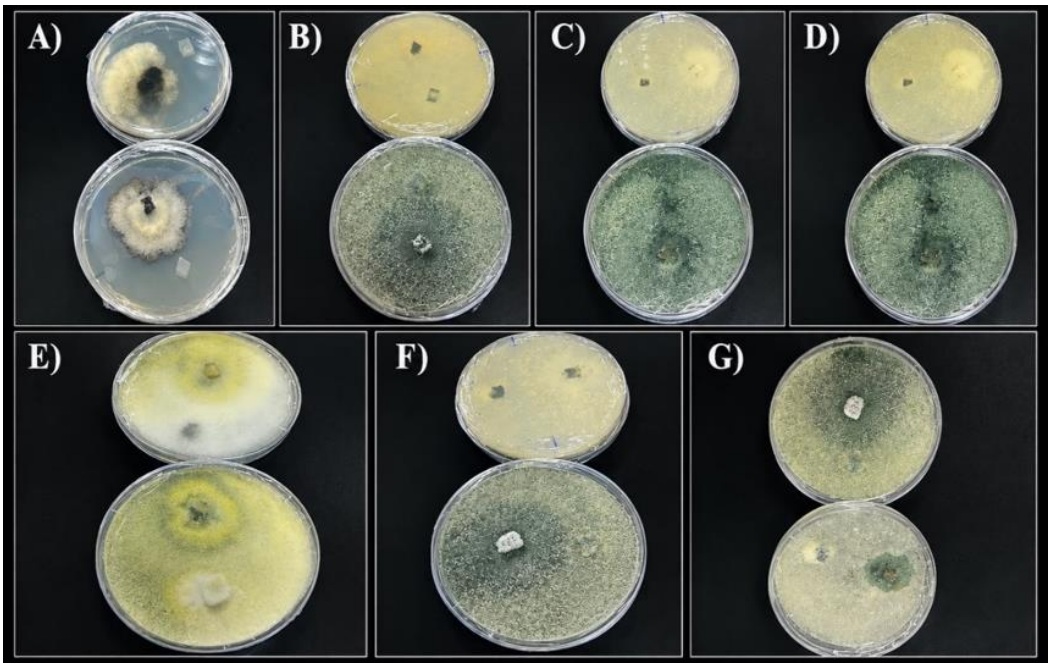

Figure 3. Dual-culture assays of different *Trichoderma* isolates against *Monilia laxa* A) *Monilia laxa* control, B) *Trichoderma harzianum* isolate isolated from Walnut, C) *T. harzianum* commercial fertilizer product, D) *Trichoderma asperellum* isolate isolated from apple, E) *Trichoderma harzianum* isolated from Apricot , F) *Trichoderma harzianum* isolate , G) *Trichoderma harzianum* isolate isolated from Strawberry

The antagonistic potential of *Trichoderma* spp. against *Fusarium* species has been widely demonstrated in previous studies. Several reports have shown that *T. harzianum*, *T. asperellum*, and other *Trichoderma* species can effectively restrict the mycelial growth of different *Fusarium* pathogens in dual-culture assays. For example, *T. harzianum* has been reported to inhibit *Fusarium oxysporum* through competition for nutrients and space, as well as mycoparasitic interactions, while *T. asperellum* has also shown considerable antagonistic activity against different *Fusarium* species (Bunbury-Blanchette and Walker, 2019; Modrzewska et al., 2022).

In addition to *Fusarium*, biological control approaches have also been investigated against *Monilinia laxa*, an important pathogen of stone fruits. Previous in vitro studies have demonstrated that microbial antagonists can substantially suppress the mycelial growth of *M. laxa*, highlighting the potential of biological control as an alternative or complementary approach to conventional disease management.

Conclusion

Overall, the results indicate that the tested Trichoderma isolates differed in their antagonistic activity against the target pathogens. The walnut-rhizosphere *T. harzianum* isolate showed strong activity against *F. acuminatum*, whereas the apple-rhizosphere *T. asperellum* isolate and the commercial *T. harzianum*-based product showed high inhibitory activity against *M. laxa*. These findings demonstrate that selected Trichoderma isolates may have potential as biological control agents against important fungal pathogens of woody and fruit crops.

However, the present study was conducted under in vitro conditions and therefore the observed antagonistic activity cannot be directly extrapolated to disease suppression under greenhouse or field conditions. Environmental factors, host–microbe interactions, pathogen population structure, formulation stability, and application timing may substantially influence biocontrol efficacy under natural conditions.

Taken together, the findings provide preliminary evidence for the biocontrol potential of selected *Trichoderma* isolates and indicate that strain selection is a critical factor in the development of effective biological control strategies against *Fusarium* spp. and *Monilinia laxa*.

Abstract
Phytopathogenic fungi are among the major constraints affecting agricultural production, causing considerable yield and quality losses in a wide range of crops. The management of fungal diseases has traditionally relied heavily on synthetic fungicides and other chemical pesticides. However, the intensive and continuous use of these chemicals has raised increasing concerns regarding environmental contamination, adverse effects on non-target organisms, pesticide residues in food, and the development of resistant pathogen populations. Therefore, the development of environmentally friendly and sustainable disease management strategies that can reduce dependence on synthetic agrochemicals has become increasingly important. In this context, biological control using beneficial microorganisms represents a promising alternative approach for the sustainable management of plant diseases. The present study aimed to evaluate the in vitro biocontrol potential of different *Trichoderma* spp. isolates against *Fusarium oxysporum*, a phytopathogenic fungus associated with disease development and yield losses in woody plants. The *Trichoderma* isolates evaluated in this study included *T. asperellum* obtained from the apple rhizosphere, as well as *Trichoderma harzianum* isolates obtained from strawberry, walnut, and apricot hosts and a commercial *T. harzianum*-based fertilizer product. The antagonistic activity of the isolates against *F. oxysporum* was investigated using dual culture assays and double-plate assays under in vitro conditions. In the dual culture tests, the effects of the *Trichoderma* isolates on the radial mycelial growth of *F. oxysporum* were evaluated, and the percentage inhibition of mycelial growth was determined. Double-plate assays were additionally performed to assess the potential role of volatile or diffusible antifungal metabolites in the antagonistic interactions. The results demonstrated that the *T. asperellum* isolate obtained from the apple rhizosphere exhibited a significant inhibitory effect on the mycelial growth of *F. oxysporum* in the dual culture assay. This finding indicates that the isolate has considerable antagonistic potential and may be a promising candidate for further evaluation as a biological control agent. In contrast, no statistically significant differences were detected among the treatments in the control assays. Overall, the findings suggest that selected *Trichoderma* isolates, particularly *T. asperellum* from the apple rhizosphere, may have potential for the biological suppression of *F. oxysporum* and could contribute to the development of sustainable alternatives to conventional chemical disease management.
Key words: *Trichoderma asperellum*, *Trichoderma harzianum*, *Fusarium oxysporum*, biological control, antagonistic activity

Özet
Fungal patojenler, tarımsal üretimi sınırlandıran başlıca etmenlerden biri olup, çok sayıda bitkide önemli verim ve kalite kayıplarına neden olmaktadır. Fungal hastalıkların mücadelesinde geleneksel olarak sentetik fungisitler ve diğer kimyasal pestisitler yoğun bir şekilde kullanılmaktadır. Bununla birlikte, bu

kimyasalların yoğun ve sürekli kullanımı; çevre kirliliği, hedef dışı organizmalar üzerindeki olumsuz etkiler, gıdalarda pestisit kalıntıları ve patojen popülasyonlarında dayanıklılığın gelişmesi gibi nedenlerle giderek artan endişelere yol açmaktadır. Bu nedenle, sentetik tarım kimyasallarına olan bağımlılığı azaltabilecek çevre dostu ve sürdürülebilir hastalık yönetimi stratejilerinin geliştirilmesi giderek daha fazla önem kazanmaktadır. Bu bağlamda, yararlı mikroorganizmaların kullanıldığı biyolojik mücadele, bitki hastalıklarının sürdürülebilir yönetimi açısından umut vadeden alternatif bir yaklaşım olarak öne çıkmaktadır.

Bu çalışmada, farklı konukçulardan elde edilen *Trichoderma* spp. izolatlarının, odunsu bitkilerde hastalık gelişimi ve verim kayıpları ile ilişkilendirilen fitopatojenik bir fungus olan *Fusarium oxysporum*'a karşı in vitro biyolojik mücadele potansiyelinin belirlenmesi amaçlanmıştır. Çalışmada değerlendirilen *Trichoderma* izolatları; elma rizosferinden elde edilen *T. asperellum* ile çilek, ceviz ve kayısıdan elde edilen *Trichoderma harzianum* izolatları ve ticari *T. harzianum* içerikli gübre ürününden elde edilen izolatı kapsamaktadır. İzolatların *F. oxysporum*'a karşı antagonistik aktiviteleri, in vitro koşullarda ikili kültür ve çift petri (double-plate) testleri kullanılarak araştırılmıştır. İkili kültür testlerinde, *Trichoderma* izolatlarının *F. oxysporum*'un radyal misel gelişimi üzerindeki etkileri değerlendirilmiş ve misel gelişiminin engellenme oranları belirlenmiştir. Ayrıca, antagonistik etkileşimlerde uçucu veya difüze olabilen antifungal metabolitlerin olası rolünü değerlendirmek amacıyla çift petri testleri gerçekleştirilmiştir.

Elde edilen sonuçlar, elma rizosferinden elde edilen *T. asperellum* izolatının, ikili kültür testlerinde *F. oxysporum*'un misel gelişimi üzerinde önemli düzeyde engelleyici etki gösterdiğini ortaya koymuştur. Bu sonuç, söz konusu izolatın güçlü bir antagonistik potansiyele sahip olduğunu ve biyolojik mücadele ajanı olarak daha ileri çalışmalar için umut vadeden bir aday olabileceğini göstermektedir. Buna karşılık, kontrol testlerinde uygulamalar arasında istatistiksel olarak önemli bir fark belirlenmemiştir. Genel olarak elde edilen bulgular, özellikle elma rizosferinden elde edilen *T. asperellum* olmak üzere, bazı *Trichoderma* izolatlarının *F. oxysporum*'un biyolojik olarak baskılanmasında potansiyel taşıdığını ve geleneksel kimyasal hastalık yönetimine sürdürülebilir alternatiflerin geliştirilmesine katkı sağlayabileceğini göstermektedir.

Anahtarlar kelimeler: *Trichoderma asperellum*, *Trichoderma harzianum*, *Fusarium oxysporum*, biyolojik mücadele, antagonistik aktivite, ikili kültür, in vitro

Introduction

Fusarium oxysporum is a widely distributed soilborne fungal pathogen and an important causal agent of vascular wilt and root and crown diseases in numerous economically important crops. The *F. oxysporum* species complex comprises both pathogenic and non-pathogenic strains, with pathogenic strains showing considerable host specialization and being classified into different formae speciales according to their host range. The pathogen has been reported from a wide range of plant species and is responsible for substantial yield and economic losses in agricultural production (Gordon, 2017; Edel-Hermann and Lecomte, 2019). Its ability to survive in soil and infect susceptible plants through the root system makes the management of *F. oxysporum* diseases particularly challenging. Therefore, the development of sustainable and effective biological control strategies against *F. oxysporum* is of considerable importance.

Among the microorganisms investigated for the biological control of *F. oxysporum*, *Trichoderma* spp. are considered important fungal antagonists because of their ability to rapidly colonize the rhizosphere and interact with plant pathogens. Their biocontrol activity can involve several mechanisms, including competition for nutrients and space, mycoparasitism, antibiosis, and the production of hydrolytic enzymes and secondary metabolites.

In addition to their direct antagonistic effects on pathogens, some *Trichoderma* strains can promote plant growth and enhance plant defense responses, contributing to overall plant health. Therefore, the selection and evaluation of effective *Trichoderma* isolates is an important step in developing sustainable management strategies for diseases caused by *F. oxysporum* (Harman et al., 2004; Benítez et al., 2004; Woo et al., 2023).

Materials And Methods

A phytopathogenic isolate of *Fusarium oxysporum* and three *Trichoderma* strains, namely *T. asperellum*, *T. harzianum*, and *T. harnatum*, were included in the in vitro experiments. The fungal

isolates had previously been identified and characterized using molecular methods. Prior to the assays, all fungal cultures were maintained on potato dextrose agar (PDA) and incubated at 26 ± 1 °C for 7 days. For each experiment, 5-mm-diameter mycelial plugs were excised from actively growing margins of the 7-day-old cultures and used as inoculum.

Dual Culture Assay

The dual-culture assay was performed following the procedure described by Rahman et al. (2009), with minor modifications. Briefly, 5-mm mycelial plugs were obtained from the actively growing margins of 7-day-old *Fusarium oxysporum* and *Trichoderma* cultures. A plug of each fungus was placed on the same PDA plate at an approximately 3-cm distance from each other. PDA plates inoculated only with *F. oxysporum* were used as pathogen controls. All plates were incubated at 26 ± 1 °C for 7 days, after which fungal growth was evaluated.

Isolation of Fungi

For the recovery of the fungal pathogen, symptomatic plant material exhibiting typical disease symptoms such as root, crown, stem, or fruit rot was collected from the relevant host plants. The samples were washed thoroughly with tap water and dried using sterile paper towels. Tissue sections approximately 2–3 mm in size were excised from the transition zone between healthy and diseased tissues. The sections were surface sterilized in 0.1% sodium hypochlorite (NaOCl) for 1–3 min, depending on the type and tenderness of the plant tissue, and subsequently rinsed with sterile distilled water. After drying, the disinfected tissue pieces were aseptically placed onto suitable isolation media and incubated under appropriate conditions. Fungal colonies emerging from the tissue pieces were transferred to fresh media and purified for further morphological and molecular characterization (Agrios, 2005).

Trichoderma isolates were recovered from rhizosphere soil collected from the root zones of the respective host plants, including apricot, walnut, apple, and strawberry. Soil samples were processed using standard procedures for the isolation of *Trichoderma* spp. from plant-associated soils. The resulting fungal colonies were purified and maintained on appropriate culture media until further identification and antagonism assays. The isolation procedure was based on methods previously described for the recovery of *Trichoderma* from soil and rhizosphere environments (Elad et al., 1981; Papavizas, 1985).

Molecular Identification of the Isolates

DNA Extraction

For molecular identification, the fungal isolates were cultivated on potato dextrose agar (PDA) at 24 °C for 10–12 days. Genomic DNA was subsequently extracted from the fungal material using the DNeasy Blood & Tissue Kit (Qiagen, Madison, WI, USA) following the manufacturer's instructions.

For the molecular characterization of *Trichoderma* isolates, the internal transcribed spacer (ITS) region was amplified using the ITS1 and ITS4 primers (White et al., 1990; Kroon et al., 2004). PCR amplification consisted of an initial denaturation step at 94 °C for 4 min, followed by 35 cycles of denaturation at 94 °C for 60 s, primer annealing at 58 °C for 60 s, and extension at 72 °C for 60 s. A final extension was performed at 72 °C for 5 min.

The RPB2 gene region was amplified for molecular identification of *Fusarium oxysporum* using the fRPB2-5F and fRPB2-7cR primer pair (Liu et al., 1999). The amplification program included an initial denaturation at 95 °C for 5 min, followed by 35 cycles consisting of denaturation at 95 °C for 1 min and annealing at 48 °C for 2 min. The temperature was then increased at a rate of 0.2 °C s^{-1} to 72 °C, followed by a 2-min extension at 72 °C. The reaction was completed with a final extension at 72 °C for 10 min.

PCR reactions were prepared in a total volume of 50 µL containing 5 µL of DNA template (approximately 10 ng), 26 µL of Thermo Scientific™ PCR Master Mix, 15 µL of nuclease-free water (Merck), and 2 µL of primer mixture. The primer sequences and amplification conditions are presented in Table 1.

Table 1. Primers and PCR conditions used for molecular identification of the fungal isolates.

Target gene region	Primer sequences	PCR protocol	Product length (bp)	References

Agarose Gel Electrophoresis and PCR Product Selection

The amplified PCR products were analyzed by electrophoresis using a 1.5% agarose gel prepared in 1× TAE buffer (40 mM Tris-acetate and 1 mM EDTA, pH 8.0). For gel preparation, 1.5 g of agarose was dissolved in 100 mL of 1× TAE buffer by heating in a microwave oven. After cooling, 5 µL of Nucleic Acid Gel Staining Solution was added per 100 mL of gel solution and mixed thoroughly. The prepared agarose was poured into a horizontal electrophoresis tray and allowed to polymerize. Following electrophoresis, DNA bands were visualized using a UV transilluminator imaging system. PCR products showing bands of the expected size were selected and submitted for sequencing.

The ITS region was amplified from the *Trichoderma* isolates using the ITS1 and ITS4 primer pair, whereas the RPB2 region was amplified from the *Fusarium oxysporum* isolate using the fRPB2-5F and fRPB2-7cR primers. The resulting sequences were compared with reference sequences available in the National Center for Biotechnology Information (NCBI) GenBank database to confirm the molecular identities of the fungal isolates.

Statistical analysis

The antagonistic effects of the *Trichoderma* isolates on *Fusarium oxysporum* were determined using the dual-culture assay. Inhibition of pathogen growth was expressed as the percentage inhibition of radial growth (PIRG), calculated according to Skidmore and Dickinson (1976) as follows: PIRG (%) = [(C − T) / C] × 100, where C is the mean radial growth of the pathogen in the control plates and T is the mean radial growth measured in the presence of a *Trichoderma* isolate. Each treatment was performed in duplicate, and the mean values for pathogen growth and PIRG were calculated. As only two replicates were included per treatment, the data were summarized using descriptive statistics without performing inferential statistical tests.

Results and Discussion

Molecular identification of the fungal isolates

Molecular identification was performed using ITS sequences for the Trichoderma isolates, whereas the RPB2 region was used for the identification of the Fusarium isolates. PCR amplification produced products of the expected sizes for the target regions, and positive amplification products were selected for sequencing. The obtained sequences were compared with sequences deposited in GenBank to support the identification of the fungal isolates.

The antagonistic activities of the tested Trichoderma isolates against the target Fusarium species were evaluated using the dual-culture assay. Differences were observed among the Trichoderma isolates in their ability to suppress the radial mycelial growth of the tested pathogens. The percentage inhibition of radial mycelial growth (PIRG) was calculated based on the radial growth of the pathogens in the control plates and in the presence of Trichoderma isolates.

The antagonistic potential of the evaluated Trichoderma isolates against *Fusarium oxysporum* demonstrated notable variation among strains. Compared to the pathogen control (mean radial growth

of 36.5 mm), the application of Trichoderma isolates restricted pathogen mycelial growth to a range of 20.0–30.0 mm (Table 2).

Among all tested strains, isolate T-3 (*Trichoderma asperellum*), obtained from apple, exhibited the strongest biocontrol efficacy, achieving a 45.2% inhibition rate and suppressing mean pathogen growth to 20.0 mm. Substantial growth suppression was also recorded for T-4 (*T. harzianum*; 39.7% inhibition, 22.0 mm growth) and T-2 (*T. harzianum* from walnut; 24.7% inhibition, 27.50 mm growth).

In contrast, isolates T-1 (*T. harzianum* from apricot) and T-5 (*T. harnatum* from strawberry) displayed lower inhibitory activity, each yielding an inhibition rate of 17.8% (30.0 mm growth). Overall, all Trichoderma isolates successfully suppressed F. oxysporum development, with T-3 showing the highest antagonistic performance. This growth suppression is likely mediated by space and nutrient competition, mycoparasitism, and antifungal metabolite synthesis (Elad et al., 1981; Papavizas, 1985)

Table 2. Antagonistic activity of Trichoderma isolates against Fusarium oxysporum based on dual-culture assay.

Isolate no	Isolate source	Pathogen fungal growth (mm)	Trichoderma growth (mm)	Inhibition of radial growth (%)	Growth differences (T - P) (mm)
T-1	Apricot- *T. harzianum*	30,00	56,00	**17,8%**	26,50
T-2	Walnut-*T. harzianum*	27,50	56,50	**24,7%**	29,00
T-3	Apple- *Trichoderma asperellum*	20	59,50	**45,2%**	39,50
T-4	*Trichoderma harzianum*	22	60,00	**39,7%**	38,00
T-5	Strawberry- *T. harnatum*	30	57	**17,8%**	27,00
Control	*Fusarium oxysporum*	36,50	0,00	**0,0%**	-

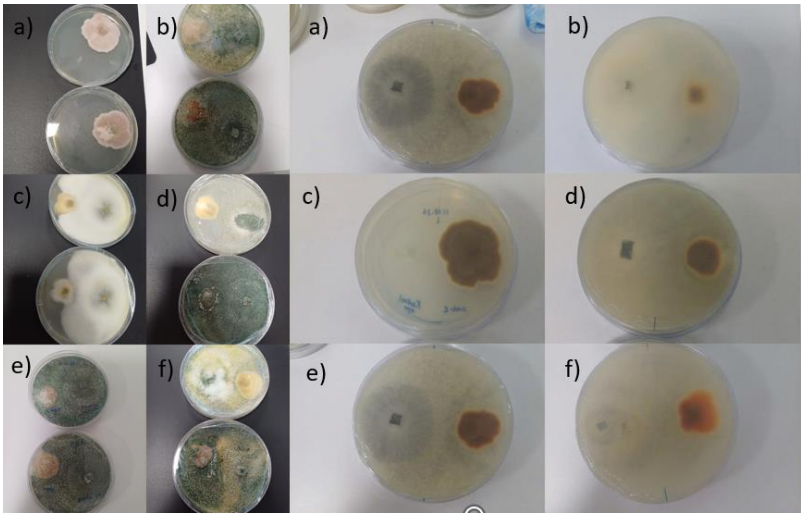

Figure 1. Dual-culture assays of *Fusarium oxysporum* against different Trichoderma isolates: a*) F. oxysporum* control, b) *Trichoderma harnatum* isolated from strawberry, c) *Trichoderma harzianum* derived from commercial fertilizer, d) *Trichoderma asperellum*

The antagonistic potential of *Trichoderma* spp. against *Fusarium* species has been widely demonstrated in previous studies. Several reports have shown that *T. harzianum*, *T. asperellum*, and other *Trichoderma* species can effectively restrict the mycelial growth of different *Fusarium* pathogens in dual-culture

assays. For example, *T. harzianum* has been reported to inhibit *Fusarium oxysporum* through competition for nutrients and space, as well as mycoparasitic interactions, while *T. asperellum* has also shown considerable antagonistic activity against different *Fusarium* species (Bunbury-Blanchette and Walker, 2019; Modrzewska et al., 2022).

Conclusion

The findings of this study revealed variation among the tested Trichoderma isolates in their ability to inhibit the growth of *Fusarium oxysporum*. The antagonistic interactions observed under in vitro conditions indicate that certain Trichoderma isolates could be promising candidates for the biological management of *F. oxysporum*. Such differences in inhibitory performance may be associated with the specific biological characteristics and antagonistic mechanisms of individual Trichoderma isolates.

Nevertheless, the results obtained in vitro should be interpreted with caution, as they do not necessarily reflect the biocontrol performance of Trichoderma under greenhouse or field conditions. The effectiveness of Trichoderma against *F. oxysporum* may be affected by several factors, including environmental conditions, interactions with the host plant and native microbial community, variability within pathogen populations, formulation characteristics, and the timing and method of application. Therefore, further experiments under controlled greenhouse and field conditions are necessary to determine the consistency and practical effectiveness of the selected Trichoderma isolates against *F. oxysporum*.

IMPORTANCE OF WHEAT PRODUCTION AND EVALUATION OF PLANT PROTECTION PROBLEMS IN SİVAS

SİVAS İLİNDE BUĞDAY ÜRETİMİNİN ÖNEMİ VE KARŞILAŞILAN BİTKİ KORUMA SORUNLARININ DEĞERLENDİRİLMESİ

Abstract
Wheat (*Triticum aestivum* L.) is a strategically important crop for human nutrition and food security. Root and crown diseases are among the major biotic constraints limiting wheat yield and quality. This review aims to evaluate the principal pathogens associated with root, crown and basal stem diseases of wheat, their symptoms, conditions influencing disease development, and integrated management approaches. Major pathogens include *Fusarium* spp., particularly *F. pseudograminearum* and *F. culmorum*, *Bipolaris sorokiniana*, *Rhizoctonia* species, *Gaeumannomyces tritici* and *Oculimacula* species. Oomycetes belonging to the genera *Pythium* and *Globisporangium* can also cause root rot. Infections may result in root and crown necrosis, poor plant growth, reduced tillering, premature senescence and impaired grain filling. Disease occurrence and severity are associated with soil temperature and moisture, inoculum density, cultivar susceptibility, crop rotation and other agronomic practices. Water stress, in particular, can exacerbate the adverse effects of certain crown rot diseases on yield. Because symptoms may overlap and multiple pathogens may coexist, reliable diagnosis requires field observations supported by morphological and molecular investigations. Healthy seed, appropriate cultivar selection, crop rotation tailored to the target pathogen, crop residue management and agronomic practices that reduce plant stress constitute the main components of integrated management. In conclusion, determining regional pathogen distribution and developing diagnosis-based management programmes are important for reducing losses caused by root and crown diseases in wheat.
Keywords: Wheat, root rot, crown rot, soilborne pathogens, disease diagnosis, integrated management.

Özet
Buğday (*Triticum aestivum* L.), insan beslenmesi ve gıda güvenliği açısından stratejik öneme sahip bir kültür bitkisidir. Buğday üretiminde verim ve kaliteyi sınırlandıran biyotik faktörler arasında kök ve kök boğazı hastalıkları önemli bir yer tutmaktadır. Bu derlemede, buğdayda kök, kök boğazı ve sap dibi hastalıklarıyla ilişkili başlıca etmenlerin, hastalık belirtilerinin, gelişimi etkileyen koşulların ve entegre mücadele yaklaşımlarının değerlendirilmesi amaçlanmaktadır. Başlıca patojenler arasında Fusarium spp., özellikle *F. pseudograminearum* ve *F. culmorum*, *Bipolaris sorokiniana*, *Rhizoctonia* türleri, *Gaeumannomyces tritici* ve *Oculimacula* türleri bulunmaktadır. Ayrıca *Pythium* ve *Globisporangium* cinslerine ait oomyceteler de kök çürüklüklerine neden olabilmektedir. Bu etmenlerin oluşturduğu enfeksiyonlar köklerde ve kök boğazında nekroz, zayıf gelişme, kardeşlenmede azalma, erken kuruma ve tane dolumunda yetersizlikle sonuçlanabilmektedir. Hastalıkların ortaya çıkışı ve şiddeti; toprak sıcaklığı ve nemi, inokulum yoğunluğu, çeşit duyarlılığı, ekim nöbeti ve diğer yetiştirme uygulamalarıyla ilişkilidir. Özellikle su stresi, bazı kök boğazı çürüklüklerinin verim üzerindeki olumsuz etkisini artırabilmektedir. Belirtilerin benzerliği ve birden fazla etmenin birlikte bulunabilmesi nedeniyle güvenilir tanıda saha gözlemlerinin morfolojik ve moleküler incelemelerle desteklenmesi önem taşımaktadır. Entegre mücadelede sağlıklı tohumluk kullanımı, uygun çeşit seçimi, hedef patojene göre planlanan ekim nöbeti, bitki artıklarının yönetimi ve bitki stresini azaltan yetiştirme uygulamaları temel bileşenlerdir. Sonuç olarak, bölgesel etmen dağılımının belirlenmesi ve tanıya dayalı mücadele programlarının geliştirilmesi, buğdayda kök ve kök boğazı hastalıklarından kaynaklanan kayıpların azaltılması açısından önemlidir.
Anahtar kelimeler: Buğday, kök çürüklüğü, kök boğazı çürüklüğü, toprak kökenli patojenler, hastalık tanısı, entegre mücadele.

GİRİŞ

Buğday (Triticum aestivum L.), dünya genelinde ekim alanı ve üretim miktarı bakımından ilk sırada yer alan önemli bir kültür bitkisidir. İnsan beslenmesinde temel besin kaynağı olma özelliğindedir. Dünya'nın ve Türkiye'nin neredeyse her bölümünde üretimi yapılan buğday; gerek çok büyük üretici kitlesini ilgilendirmesi, gerekse insanların temel gıdası olan ekmeğin hammaddesini oluşturması bakımından oldukça önemli bir üründür (Kızılaslan, 2004). Buğday üretiminde çeşitli yöntemlerle artış sağlanabilmesine karşın, önemli ürün kayıplarına yol açan çok sayıda faktör de bulunmaktadır. Buğday hastalıkları ve özellikle bunlardan da kök ve kök boğazı hastalıkları buğday verimini sınırlayan en önemli faktörler arasında yer almaktadır.

Türkiye'de kışlık buğdayda %43 (Hekimhan ve ark., 2004), Orta Anadolu Platosu'ndaki (OAP) makarnalık buğdayda ise %54 oranında kayıplar rapor edilmiştir (Bağcı ve ark., 2001). Aktaş ve ark. (1999), kök ve kök boğazı çürüklükleri sonucunda kışlık tahıllarda %36 oranında hastalık yoğunluğu bildirmiştir. Kışlık buğdayın ana ürün olduğu Orta Anadolu Platosu, yıllık 250-500 mm yağış alan 10 milyon hektarlık tarım arazisini kapsamaktadır (Benli ve ark., 2007). Dünyada hastalıklar nedeniyle oluşan verim kayıplarının; Amerika'nın Pasifik Kuzeybatı (PNW) bölgesindeki kışlık buğdayda %35'e (Smiley, 2005), Avustralya'da %25-58'e ulaştığı, hastalığın bazı durumlarda %89'a kadar kayıp yaşatabildiği (Klein, 1991; Chakraborty ve ark., 2010) ve Tunus'ta %49'a vardığı (Chekali, 2016) bildirilmiştir.

Buğdayda kök ve kök boğazı hastalıklarına neden olan en yaygın etmenler Fusarium spp. ve Rhizoctonia spp. olup bunların yanı sıra Drechslera sorokiniana, Pythium graminicolum, Pseudocercosporella herpotrichoides ve Ophiobolus graminis sıklıkla görülen patojenlerdir (Aktaş, 2001). Buğdayda görülen fungal hastalıklar; tohum ve başak hastalıkları, yeşil aksam ve yaprak hastalıkları ve kök, kökboğazı ve sap hastalıkları olmak üzere sınıflandırılabilir. Buğday bitkilerinin kök, kökboğazı ve sap kısmında yanıklık veya çürüklük benzeri simptomlara neden olan önemli fungal etmenler; Bipolaris, Fusarium, Gaeumannomyces, Pseudocercosporella, Pythium ve Rhizoctonia cinslerine bağlı fungus türleridir.

Biyotik stres faktörleri arasında; kışlık tahıllarda kök, kök boğazı ve sap çürümelerine neden olan Fusarium türleri, dünya çapında tahıl odaklı tarım sistemlerinin hakim olduğu hemen her yerde görülmektedir (Burgess ve ark., 2001). Hastalığa öncelikle Fusarium culmorum, F. pseudograminearum ve F. graminearum neden olmaktadır. Fusarium türlerinin genomik yapısı ve konakçıya özelleşme mekanizmaları üzerine yapılan araştırmalar, bu patojenlerin çevresel koşullara hızlı adapte olabildiğini ve virülans faktörlerinin genomik düzeyde çeşitlilik gösterdiğini ortaya koymaktadır (Ma ve ark., 2013). Bu durum, Sivas ili buğday ekim alanlarında saptanacak patojen profillerinin ve bunların patojenisite düzeylerinin belirlenmesinin, bölgesel mücadele stratejileri açısından önemini pekiştirmektedir.

Rhizoctonia cinsi dünyanın her yerinde ve ülkemizde yaygın olarak bulunan önemli toprak patojenlerinden birisidir. Fungus kendi içerisinde çeşitlilik gösteren, geniş ve kompleks bir gruptur (Carling ve Summer, 1992). Çevresel koşullara yüksek oranda adaptasyon göstermesi nedeniyle tüm dünyaya yayılmıştır ve dünyada ekonomik açıdan önemli 200'ü aşkın bitkide yıllık ortalama %20'den fazla ürün kaybına neden olmaktadır (Clarkson ve Cook, 1983; MacNish ve Neate, 1996; Cromey ve ark., 2002).

Rhizoctonia, dünya genelinde tarım alanlarında yaprak ve kök çürüklüğü hastalıklarına neden olan, ekonomik açıdan en önemli bitki patojenlerinden biridir. Rhizoctonia türleri sklerotları ile toprakta uzun süre canlı kalabilmektedir. Ayrıca saprofitik rekabetçiliği, patojenik özellikleri, çok hızlı gelişimi ve geniş konukçu dizisi nedeniyle sorun oluşturan bir cins olarak bilinmektedir. Bu nedenle hastalığın kimyasal mücadelesi zordur ve ancak sınırlı alanlarda kısmen başarılı olabilmektedir (Mohammadi ve ark., 2003).

Bipolaris sorokiniana arpa ve buğday bitkilerinde önemli bir patojen olup, ülkemizde özellikle iç kesimlerde ve dünyada ılıman iklim kuşağında önemli ekonomik kayıplara yol açmaktadır. Yapılan bir araştırmada, Orta Anadolu Bölgesi'nde hastalığın arpa ekim alanlarının 1/3'ünün bu hastalıkla bulaşık olduğu belirlenmiştir (Aktaş ve Tunalı, 1994). Göbelez (1952) ise B. sorokiniana'nın Konya Ereğli'sinde tarlalarda %50 yaygınlıkta olduğu ve farklı tarlalardan alınan arpa bitkilerinin %15-40 arasında bu patojenle bulaşık olduğunu belirlemiştir. B. sorokiniana'nın konidioforları koyu kahverengi, kısa ve çoğunlukla tek veya küçük gruplar halinde düz veya kıvrık, konidiosporları ise 3-10 bölmelidir. Hastalık etmeni bir yıldan diğerine tohumlarla ve tarlada kalan hastalıklı bitki artıklarıyla geçmektedir. Pseudocercosporella herpotrichoides'in vejetatif miselleri genellikle sarı ile kahverengi uzun hücrelere sahip olup, stroma miselleri ise çok hücreli kalın duvarlı ve poligonaldir. Bitkide yaralar içinde fungusun

miselleri bulunur. Sporları çoğunlukla 5-7 bölmeli olup, PDA besiyerinde az sayıda da olsa gelişebilen, ince uzun yapıdadır. Fungus enfekteli bitki artıklarında yaşamını sürdürür. İlkbahar yağışlarında fungusun hifleri genç yaprak kınlarına ulaşır ve yaprakları enfekte eder. Buğday ekiminin yoğun olduğu bölgelerde patojen profilinin saptanması, o bölgede alınacak kültürel tedbirler ve mücadele stratejilerine yol gösterebilmektedir.

Yapılması planlanan yüksek lisans tez çalışması kapsamında Sivas ili ve ilçelerindeki buğday ekim alanlarında görülebilecek kök, kökboğazı ve sap çürüklüğü hastalığı etmenlerinin belirlenmesi, hastalıkların yaygınlık ve bulunuş oranlarının ortaya çıkarılması hedeflenmektedir.

YÖNTEM

Sivas ili ve ilçelerine bağlı buğday ekim alanları incelenmiştir. Sörvey çalışmasında bitkilerin büyüme dönemleri esas alınacak ve buğdaylar süt olum dönemine ulaştığında (Zadoks skalasına göre 75. dönem; Zadoks ve ark., 1974) ilk sörvey çıkışı yapılmıştır. Bu amaçla söz konusu buğday tarlalarının farklı bölgelerinden rastgele seçilen buğday bitkileri kökleri ile birlikte alınarak etiketlenmiş, o tarlaya ait bilgiler ve alındığı tarihler not edilerek plastik torbalar içerisinde laboratuvara getirilmiştir. Tarlalara ait GPS konum bilgileri de alınmıştır. Laboratuvar ortamına getirilen materyaller, simptomatolojik inceleme ve izolasyon aşamalarına kadar canlılığını koruması amacıyla +4°C'de buzdolaplarında muhafaza edilmiştir. Araziden getirilen bitki materyalleri çeşme suyu altında dikkatlice yıkanarak toprak kalıntılarından arındırılmış; kök ve kök boğazı bölgeleri yaprak kınlarından temizlenerek incelemeye hazır hale getirilmiştir. Tarlalardan toplanan bitkiler incelenmeye alınmıştır. Bitkilerdeki kök ve kök boğazı semptomları, Wildermuth ve McNamara (1994) tarafından geliştirilen hastalık değerlendirme skalasına göre değerlendirilecektir.

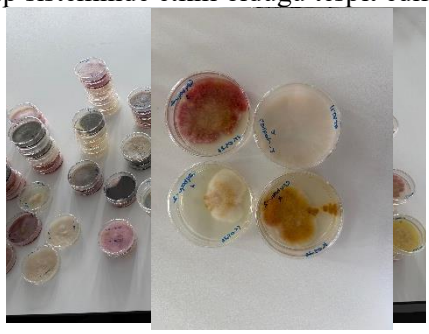
Hastalık çıkışı hesaplamasında simptomatolojik olarak incelenen 100 bitkiden sağlıklı olanların sayısı çıkarılacak ve oluşan fark ile hasta bitkilerin oranı belirlenecektir. Hastalık şiddetini belirlemek amacıyla Townsend ve Heuberger formülü uygulanacaktır (Karman, 1971):

Hastalık Şiddeti (%) = [Σ (Skala Değeri × Skala Değerine Dahil Olan Bitki Sayısı) / (Toplam Bitki Sayısı × En Yüksek Skala Değeri)] × 100

Bu şekilde her bir tarla için hesaplanan hastalık çıkışı ve hastalık şiddeti değerlerinin ortalamaları alınarak, Sivas ve ilçelerdeki ortalama değerler elde edilecektir.

İnfekteli buğday bitkileri simptomatolojik olarak incelendikten sonra kök, kök boğazı ve sap bölgelerinden standart mikolojik izolasyonlar yapılacaktır. Elde edilen izolatlar cins düzeyinde ayırt edilecek, bu fungusların izole edilme oranları hesaplanacaktır. İzolasyonlar sonucunda tanısı yapılan fungus türlerinin patojenisite çalışmaları Liddell ve ark. (1986) ile Wildermuth ve McNamara (1994)'ya göre yapılacaktır. Patojenisite çalışmaları 3 tekerrürlü olarak Sivas Bilim ve Teknoloji Üniversitesi (SBTÜ) iklim odalarında yürütülecektir.

ARAŞTIRMA BULGULARI VE TARTIŞMA



Sivas ili ve ilçelerindeki buğday ekim alanlarında gerçekleştirilen sörvey çalışmaları sonucunda, bitkilerin kök, kök boğazı ve sap bölgelerinde kahverengi lezyonlar, nekrotik çökmeler, iletim demetlerinde esmerleşme gibi tipik kök ve kök boğazı çürüklüğü simptomları gözlemlenmiştir. Aynı zamanda sörvey esnasında bitkilerde sarı pas ve septorya yaprak lekesi hastalıklarının bulgularına da rastlanmıştır.

Bitkilerin süt olum döneminde (Zadoks 75) yapılan incelemelerde, incelenen tarlaların büyük bir kısmında farklı düzeylerde hastalık çıkışı ve şiddeti saptanmıştır. Araziden toplanıp laboratuvara +4°C'de muhafaza edilerek getirilen örneklerin çalışmaları sonucunda fungal patojenlere rastlanmıştır.

Elde edilen bulgular, dünya genelinde ve Türkiye'nin tahıl üretim merkezlerinde kök ve kök boğazı çürüklüğü etmenlerinin yaygınlığını ortaya koyan önceki çalışmalarla büyük ölçüde paralellik göstermektedir. Kışlık buğdayda kök ve kök boğazı hastalıklarının ülkemizde %43 (Hekimhan ve ark., 2004), Orta Anadolu Platosu'nda ise yüksek oranlarda verim kayıplarına yol açabildiği bilinmektedir. Özellikle Fusarium türlerinin (F. culmorum, F. pseudograminearum ve F. graminearum) tahıl üretiminin olduğu alanlarda evrensel bir sorun olduğu ve bu türlerin genetik adaptasyon yetenekleri ile virülans çeşitliliğinin yüksek olduğu bilinmektedir. Sivas ili ekim alanlarında saptanan patojen profilleri, bu adaptasyon yeteneğinin bölgesel düzeydeki yansımasını açıkça göstermektedir.

Toprak patojeni olarak geniş bir konukçu dizisine sahip olan Rhizoctonia cinsinin, çevresel koşullara yüksek adaptasyon göstererek ekonomik kayıplara neden olduğu literatürle uyumludur (Carling ve

Summer, 1992; Clarkson ve Cook, 1983). Benzer şekilde, ılıman iklim kuşağında ve iç kesimlerde arpa ve buğdayda önemli kayıplara yol açan Bipolaris sorokiniana'nın (Aktaş ve Tunalı, 1994) Sivas koşullarında da buğday kök ve sap sisteminde etkili olduğu tespit edilmiştir.

Şekil 1. Buğday örneklerinden izole edilen kök ve kök boğazı patojeni fungus kültürlerinin genel görünümü.

SONUÇ

Buğday, Türkiye'de en çok yetiştirilen tahıl ürünlerinden biridir. Bu çalışma sonucu, buğday kök hastalıklarının, buğday üretimi için potansiyel bir tehdit olarak ortaya çıkan en önemli hastalıklardan biri olduğunu göstermiştir. Buğday kök hastalıklarının yaygınlık, bulunma oranı ve şiddeti Sivas ilinin bölgelerinde değişiklik göstermesine rağmen, hastalık şiddeti, bulunma oranına göre genellikle yaygın olarak belirlenmiştir. Sivas ilindeki hastalıklar, yüksek hastalık bulunma oranı ve şiddeti, muhtemelen çevresel koşulların varlığı, iklim değişikliği ve kültürel uygulamalardaki hatalardan kaynaklanmıştır. Buğday kök ve kökboğazı hastalıklarının bulunma oranı ve şiddeti üzerine etkili olan iklimsel ve biyofiziksel faktörlerin ayrıntılı araştırılmasına ihtiyaç vardır.

HASSAS HAYVANCILIK: SÜRDÜRÜLEBİLİR HAYVANCILIĞI DESTEKLEMEYE VE ÇEVRESEL RİSKLERİ AZALTMAYA YÖNELİK BİR YAKLAŞIM

PRECISION LIVESTOCK FARMING: AN APPROACH TO SUPPORTING SUSTAINABLE LIVESTOCK FARMING AND REDUCING ENVIRONMENTAL RISKS

Assos. Prof. Dr. Gökçe ÖZDEMİR
Sivas Cumhuriyet University, Faculty of Veterinary Medicine, Department of Animal Science, 58140, Sivas, TÜRKİYE
ORCID NO: 0000-0003-1977-130X

Özet
Hayvancılığı; ekonomik, sosyal ve çevresel olarak daha sürdürülebilir bir hale getirmek, yönetim stratejilerini desteklemek için; hayvanlardan iyi bir verimlilik ve üreme performansı elde etmek, hayvan sağlığı ve refahını korumak, hayvansal üretim sürecinde birim başına çevresel etkiyi azaltmak bir zorunluluktur. Hassas hayvancılık (Precision livestock farming, PLF), sürdürülebilir bir hayvancılığın bu amaçlarına ulaşabilmek için iyi bir potansiyele sahiptir. Sürdürülebilir bir hayvansal üretim sistemine geçiş yolunda yetiştiricilere büyük fırsatlar sunabilecek bir araç olarak hassas hayvancılık, hayvanların yaşamını iyileştirmeye odaklanan, gerçek zamanlı olarak hayvanları otomatik izleme ve yönetim sistemi aracılığıyla yetiştiricilerin hemen harekete geçebilmesine imkan sunan, aktif bir şekilde sürece dahil olabildikleri karar destek sistemlerini hayata geçiren, hayvan sağlığı ve refahı, ürün veriminin ve çevresel etkilerinin izlenmesi ve iyileştirilmesini mümkün kılan bir yaklaşımdır. Bu çalışmada, hassas hayvancılık uygulamalarının hayvansal üretim sürecinden kaynaklanabilen çevresel etkiyi azaltmak ve çevre dostu sürdürülebilir bir hayvancılık için potansiyelini ele almak ve bu konudaki genel tartışmaya katkıda bulunmak amaçlandı.
Anahtar Kelimeler: Hassas Hayvancılık, Sürdürülebilirlik, Çevre Etkileri, Hayvan Sağlığı, Hayvan Refahı.

Abstract
To make livestock farming more economically, socially, and environmentally sustainable and to support management strategies, it is essential to achieve good productivity and reproductive performance in animals, protect animal health and welfare, and reduce the environmental impact per unit in the livestock production process. Precision livestock farming (PLF) holds great potential for achieving these goals of sustainable livestock farming. As a tool that can offer farmers significant opportunities on the path to transitioning to a sustainable livestock production system, is an approach that focuses on improving animal welfare, enables producers to take immediate action through real-time automated animal monitoring and management systems, implements decision-support systems that actively involve producers in the process, and facilitates the monitoring and improvement of animal health and welfare, production efficiency, and environmental impacts. The aim of this study was to examine the potential of sustainable livestock farming practices to reduce the environmental impact that may arise from the livestock production process, to explore their potential for environmentally friendly and sustainable livestock farming, and to contribute to the broader discussion on this topic.
Key Word: Precision Livestock Farming, Sustainability, Environmental Impacts, Animal Health, Animal Welfare.

Giriş

Hayvancılık küresel boyutta dinamik bir sektör olup, doğal kaynaklar, arazi ve su kullanımı, karbon kısıtlamaları, çevre ve hayvan sağlığına dair tüm düzenlemelerden etkilenmektedir. Hassas hayvancılık uygulamalarının (Precision livestock farming, PLF), hayvansal üretime aktarılması ile; verimlilik, hayvan refahı, sağlığı ve sürü yönetimi gibi konularda gelişmeler sağlanmasının yanı sıra hayvansal üretim sürecinden kaynaklanabilen çevresel etkiyi minimize etmek gibi ikincil kazanımlarda sağlanmaktadır (Berckmans, 2017; Fournel et al., 2017; Tullo et al., 2019; Lovarelli et al. 2020; Kahraman ve Yılmaz, 2024).

Sürdürülebilir bir hayvansal üretim sistemine geçiş yolunda hassas hayvancılık, yetiştiricilere büyük fırsatlar sunabilecek bir araçtır. Hassas hayvancılık, hayvanların yaşamını iyileştirmeye odaklanan, gerçek zamanlı olarak hayvanları otomatik izleme ve yönetim sistemi aracılığıyla yetiştiricilerin hemen

harekete geçebilmesine imkan sunmaktadır. Hassas hayvancılık uygulamalarının benimsenmesi ile, hayvanlarının sağlığı ve refahının güvence altına alınması, verimlilik ve üreme performansının artırılması, hayvan başına verime karşılık çiftliklerin çevresel etkilerin azaltmasına katkı sağlanabildiği bildirilen birçok çalışma bulunmaktadır (Berckmans, 2014; Fournel et al., 2017; Tullo et al., 2019; Lovarelli et al. 2020; Kahraman ve Yılmaz, 2024).

Bu çalışmada, hassas hayvancılık uygulamalarının hayvansal üretim sürecinden kaynaklanabilen çevresel etkiyi azaltmak ve çevre dostu sürdürülebilir bir hayvancılık için potansiyelini ele almak ve bu konudaki genel tartışmaya katkıda bulunmak amaçlandı.

Hassas Hayvancılık

Hassas Hayvancılık (PLF), hayvan üretimini otomatik olarak izlemek, modellemek ve yönetmek için süreç mühendisliği prensip ve tekniklerinin hayvancılığa uyarlanması ile geliştirilmiş bir sistemdir (Berckmans, 2017; Fournel et al., 2017; Tullo et al., 2019). Hassas hayvancılık, hayvancılık bilgi teknoloji ve yönetim süreçlerini kullanılarak; hayvanların verimliliği ve performansı optimize etmek, kayıpları azaltmak, ürün kalitesini artırmak, mevcut kaynakları iyi şekilde kullanmak ve yoğun üretim sistemi içerisinde her bir hayvanın ihtiyacını daha iyi bir şekilde karşılamak için geliştirilen yeni bir araç olarak görülmektedir (Berckmans, 2017; Tullo et al., 2019; Lovarelli et al. 2020; Kahraman ve Yılmaz, 2024).

Hayvansal üretimde küresel boyutta; teknolojik gelişmelere dayanan hassas hayvancılık uygulamaları itici güç olarak kullanılmaktadır (Berckmans, 2014; Berckmans, 2017; Tullo et al., 2019; Losacco et al., 2025). Hassas hayvancılık, genel olarak çevresel sürdürülebilirlik, hayvan refahı ve kaynak kullanım verimliliği gibi acil endüstri sorunlarına da odaklanmaktadır. Bireysel hayvan yönetimini geliştirmek üzere tasarlanmış yapay zeka, nesnelerin interneti, bulut bilişimi, büyük veri analitiği ve makine öğrenimi tabanlı sistemlerin hayvansal üretim süreçlerine entegre edildiği hayvan odaklı bir yaklaşımıdır (Tedeschi et al., 2026; Vlaicu et al., 2024; Losacco et al., 2025). Hassas hayvancılık uygulamaları bütün olarak; sürdürülebilirlik, hayvan davranışı, sağlığı, refahı ile barınak koşulları gibi çok boyutlu hayvansal üretim yönlerini, yönetim stratejileri ve teknoloji kullanımını da kapsamaktadır (Place and Mitloehner, 2014; Tullo et al., 2019; Lovarelli et al. 2020).

Hassas hayvancılık uygulamaları; hayvanların biyolojik tepkilerinin tanımlanması, sınıflandırılması, hayvan davranışları, seslendirmeleri ve hayvan-çevre etkileşiminden kaynaklanan parametrelerin belirlenmesi, hayvanların biyolojik tepkilerinin modellemesi, hayvanların izlenmesi ve yönetimsel kararların alınması gibi adımları içermektedir (Berckmans, 2017; Fournel et al., 2017; Tullo et al., 2019; Kahraman ve Yılmaz, 2024). Bu amaçla; kamera, mikrofon, sensörler, internet bağlantıları ve bulut depolama gibi teknolojiler kullanılarak, çiftlikteki hayvanların fizyolojik, davranışsal parametreleri ile çevresel değişkenlerin otomatik olarak izlenmesi, kontrol edilmesi ve gerekli müdahalenin yapılması sağlanabilmektedir (Berckmans, 2014; Berckmans, 2017; Tullo et al., 2019; Kahraman ve Yılmaz, 2024). Bu sistem basamakları öncelikle sürekli olarak hayvanların ve ortamın takip edilmesi, verilerin toplanması, verilerin depolanması, hayvan sağlığı ve refahı ölçüm kriterlerini değerlendiren modellerin kullanılarak ölçümlerin yorumlanması ve her bir işlem çıktısı için hedef değerler doğrultusunda belirlenmiş kontrol sistemlerinin devreye sokulduğu bir iş akışını içermektedir (Fournel et al., 2017; Tullo et al., 2019; Kahraman ve Yılmaz, 2024).

Hassas hayvancılık uygulamaları sayesinde çiftliklerde; hayvan verimi, endemik hastalıkları, barınaklarının fiziksel ortamı gibi unsurlar doğrudan ve gerçek zamanlı izlenerek hayvanlar için uygun koşulların sağlanması ve bu yolla gelecekte sürdürülebilir bir hayvancılığa ulaşılmasının mümkün olabileceği bildirilmektedir (Berckmans, 2014; Fournel et al., 2017; Tullo et al., 2019; Kahraman ve Yılmaz, 2024). Hassas hayvancılık, gübre yönetimi, su tüketimi, yenilenebilir enerji kaynakları gibi çevresel etkilerin azaltılmasından sorumlu kaynak yönetiminin teşvik edilmesine kadar birçok alanda sürdürülebilir uygulamaların geliştirilmesine aracılık etmektedir (Vlaicu et al., 2024; Tedeschi et al., 2026; Losacco et al., 2025).

Çevresel riskleri azaltmaya ve sürdürülebilirliği desteklemeye yönelik hayvancılık stratejileri

Hayvancılık sektörü; arazi, su ve enerji gibi sınırlı doğal kaynaklar için giderek daha fazla rekabet etmektedir. Hava, su ve toprak kalitesi üzerinde etkiler yaratmaktadır. Bu etkinin, fosil yakıt kullanımı, ormansızlaşmadan kaynaklanan karbondioksit emisyonu, geviş getiren hayvanların gübresinden ve bağırsak fermantasyonundan kaynaklanan metan emisyonu ve yetiştirme sırasında gübre

uygulamasından kaynaklanan azot oksit emisyonuna katkılar şeklinde birçok yolla gerçekleştiği bildirilmektedir. Hayvancılığın, küresel sera gazı emisyonlarının yaklaşık %18'inden sorumlu olduğu bildirilmektedir (de Vries and de Boer, 2010; Gerber et al., 2013; Kaufmann, 2015; Tullo et al., 2019; Lovarelli et al. 2020; Şeremet Tuğalay ve Güler, 2022).

Barınaklarda mikro klima üzerinde kontrol sağlamaya olanak tanıyan hassas hayvancılık uygulamaları; hayvan sağlığı ve refahı ile, hayvancılığın çevresel sürdürülebilirliğine ulaşmak için iyi bir yaklaşım olarak önerilmektedir (Berckmans, 2014; Berckmans, 2017; Fournel et al., 2017). Bu ve benzeri hassas hayvancılık uygulamalarının çiftliklerde yaygınlaştırılması, hayvansal üretim süreçlerinden kaynaklanan çevresel kirleticilerin başında gelen havadaki sera gazı (GHG) ve amonyak (NH_3) emisyonlarında, su kaynaklarındaki nitrat ve antibiyotik kirliliğinde, topraktaki fosfor, antibiyotik ve ağır metal düzeylerinde azalma sağlanabildiği bildirilmektedir (Tullo et al., 2019; Kahraman ve Yılmaz, 2024).

Lovarelli et al. 2020, tarafından yürütülen bir çalışmada; sağlık, hayvan performansı ve üretim gibi hayvancılığın temel konuların sürdürülebilirliğin üç temel unsurunun bağlantıların kesiştiği alanın hassas hayvancılığı tanımladığı bildirilmektedir. Hassas hayvancılık uygulamalarının hayvancılık üretiminin sürdürülebilirliğine, olumlu etkileri olduğu ve ekonomik, sosyal, çevresel alanlardan birine müdahale edilmesi ile diğer alanların da etkilendiği vurgulanmaktadır. Hayvanların sağlık koşullarının iyileştirilmesi, ilaç maliyetlerini düşürmeyi, hayvan refahını iyileştirmeyi, üretim kayıplarını önlemeyi ve üretimi artırmayı aynı zamanda çevresel, ekonomik ve sosyal sürdürülebilirliğini de iyileştirmeyi sağladığı ve bu durumun ise, hassas hayvancılık ve sürdürülebilirlik arasındaki en umut verici bağlantıyı ortaya koyduğu bildirilmektedir (Lovarelli et al. 2020).

Hayvancılığın çevresel etkilerini azaltmak amacıyla temelde hayvancılık sisteminin yoğunlaştırılması için yapısal değişiklikler, teknik ve yönetimsel müdahaleler yapılmaktadır. Bu amaçla; üretim verimliliğinin, yetiştirmenin ve hayvan sağlığının iyileştirilmesi; gübredeki besin maddelerini ve enerjiyi dönüştürüp geri kazanmak için gübre yönetimi uygulamalarının kullanılması; yem gibi düşük emisyonlu girdilerin temin edilmesi; amino asitler, enzimler ve fitobiyotikler gibi bağırsak düzenleyici ürünlerin yem katkı maddesi olarak kullanılması, yeni teknoloji ve hassas hayvancılık uygulamalarının benimsenmesi gibi stratejiler hayvancılıkta sürdürülebilirliği sağlayacak çözüm önerileri arasında sayılmaktadır (Kaufmann, 2015; Tullo et al., 2019; Lovarelli et al. 2020).

Hayvan sağlığının iyileştirilmesi ve hayvanlardaki hastalık ve ölüm oranlarının azaltılması; karbon ayak izini azaltılması, bağırsak fermantasyonundan ve hayvan gübresinden kaynaklanan metan (CH_4) ve azot oksit (N_2O) emisyonlarını azaltılması potansiyeline sahip olduğu bildirilmektedir (de Vries and de Boer, 2010; Van Hertem et al., 2016; Galioto et al., 2017; Tullo et al., 2019; Kahraman ve Yılmaz, 2024). Ancak, farklı hayvancılık sistemleri, türler ve iklimler arasında değişebilen koşullarda genel sürdürülebilirlik sağlanabilmesi için, hiçbir önlem tam olarak tek başına emisyon azaltma potansiyel sahip olmadığından, en iyi sonuca ulaşmak için mevcut seçeneklerin birlikte ve seçilen bir kombinasyon şeklinde uygulanmasının faydalı olacağı da vurgulanmaktadır (Leinonen and Kyriazakis, 2016; Llonch et al., 2017; Grossi et al., 2019).

Uygulamada Karşılaşılan Bazı Riskler ve Zorluklar

Hassas hayvancılık, hayvan sağlığı ve refahını sürekli ve gerçek zamanlı olarak izlemek üzere tasarlanmıştır. Hayvancılığın çevresel etkileri ile mücadele temel hedefleri arasında değildir (Tullo et al., 2019). Ancak, bazı araştırmacıların bu perspektiften gerçekleştirdikleri analizleri hassas hayvancılığın çevresel etkilere yönelik kazanımları sağladığını doğrulanmaktadır. Henüz sürdürülebilirlik unsurları için geliştirilmiş özel yöntemleri kapsayan hassas hayvancılık uygulamaları üzerine araştırmalar sınırlı düzeydedir ve daha fazla çalışmaya ihtiyaç vardır (de Vries and de Boer, 2010; Place and Mitloehner, 2014; Kaufmann, 2015; Tullo et al., 2019; Lovarelli et al. 2020; Şeremet Tuğalay ve Güler, 2022).

Araştırmacılar ve üreticiler arasında yakın işbirliği kurulması gerekliliği ile çoğu çiftçi ve diğer paydaşların, karmaşık modelleri ve teknolojileri etkili bir şekilde kullanmak için eğitilmesi ve bu teknolojilerin yaygınlaştırılması, enerji, internet ekipman maliyeti ve temini gibi konunun ekonomik boyutları ile etik, veri güvenliği, rekabet ve refah gibi sosyal boyutları da dikkate alınması gereken zorluklardan bazılarıdır (Fournel et al., 2017).

Sonuç ve Öneriler

Uygun bir sürdürülebilir üretim için hassas hayvancılık, hem yoğun hem de yaygın yetiştirme sistemlerinde hayvanların izlenmesine olanak tanıyan, uygulanabilirliği olan, yakın gelecekte önemli bir çözüm araçtır.

Hayvancılık sektöründeki kaynak tüketimi, yaygın çevresel etkileri göz önüne alındığında, hassas hayvancılık uygulamalarının hayvancılık işletmelerinin çevresel performansını daha sürdürülebilir bir geleceğe doğru iyileştirme konusunda büyük bir potansiyel sahip olduğu yönde ortak görüşler bulunmaktadır.

Çevresel, ekonomik ve sosyal açıdan olumlu etkiler yaratarak; hayvan, çiftçi, toplum ve tüketicileri de kapsayacak şekilde yaygınlaşabilmesi için, sürekli iyileştirmeler gerektiği ve hayvancılık üretiminin sürdürülebilirliğini artırmak için daha fazla disiplinlerarası araştırmaya ihtiyaç duyulduğu görüşüne ulaşılmaktadır.

Abstract
This study aimed to spatially assess soil erosion risk in the Erfelek Watershed of Sinop Province, Türkiye, using the CORINE model integrated with Geographic Information Systems (GIS). Soil texture, soil depth, slope, and land cover were used as the main parameters of the erosion assessment. Soil-related layers were prepared using available soil data and information obtained from sampling points, while slope classes were derived from a digital elevation model with a 10 m spatial resolution. Land cover was evaluated based on CORINE 2018 land-cover classes. A common valid analysis area of 52,281.07 ha was used to ensure consistent comparison of the model outputs. Since spatially explicit stoniness data were unavailable for the study area, two alternative stoniness scenarios (S1 and S2) were developed to assess the influence of this parameter on erosion-risk estimates. Under S1, 49.12% of the analysis area was classified as low, 50.68% as moderate, and 0.20% as high potential erosion risk. Under S2, the proportion of low-risk areas decreased to 12.34%, whereas moderate- and high-risk areas increased to 57.96% and 29.71%, respectively. After incorporating the protective effect of land cover, actual erosion risk under S1 was classified as 82.94% low, 16.74% moderate, and 0.32% high. Under S2, the corresponding proportions were 46.04%, 46.10%, and 7.86%, respectively. The results demonstrate that alternative assumptions regarding stoniness can substantially alter the spatial distribution of erosion risk estimated by the CORINE model. Furthermore, land cover exhibited a pronounced protective effect, particularly by reducing the extent of high-risk areas. The scenario-based approach provides a practical framework for quantifying model uncertainty in regions where spatially detailed stoniness information is unavailable.
Keywords: CORINE, soil erosion, GIS, Erfelek Watershed

1. INTRODUCTION

Soil erosion is widely recognized as one of the major soil degradation processes threatening the functions of soil, one of the most important natural resources, within terrestrial ecosystems. Although soil erosion occurs under natural environmental conditions, it can be substantially accelerated by anthropogenic pressures such as inappropriate, unplanned, or non-purpose land use, intensive and poorly managed agricultural practices, land clearing and deforestation, and rangeland degradation caused by overgrazing. In particular, the removal of fertile topsoil by erosion can reduce soil health, quality, and productivity; impair soil functions such as water infiltration and storage and carbon and nutrient cycling; and adversely affect water resources through sediment transport. For these reasons, FAO identifies soil erosion as one of the major global threats to soil resources.

The occurrence and severity of soil erosion do not depend on a single parameter, but result from interactions among human activities, soil properties, topography, climate, and land cover/use. Soil structure, texture, depth, and surface roughness influence susceptibility to erosion, whereas topographic characteristics such as slope gradient, form, and length are particularly important in controlling runoff generation and erosion processes. Vegetation cover also determines the degree to which the soil surface

is exposed to or protected from the direct impact of rainfall and therefore influences the transition from potential erosion risk to the actual risk under existing land conditions. The CORINE erosion-risk approach similarly integrates these parameters to classify erosion risk spatially.

At the planning stage, assessment of erosion risk at watershed and regional scales requires the rapid and integrated evaluation of areas with different spatial characteristics. Geographic Information Systems (GIS) provide an effective framework for integrating soil, topographic, and land-cover data obtained from different sources within a common spatial structure and for visualizing areas with different levels of erosion risk.

One approach used for this purpose is the CORINE (Coordination of Information on the Environment) erosion model (1992), which was developed within the European Community to assess and map soil erosion risk and important land resources. The model provides a framework for generating comparable erosion-risk information, particularly over large areas. However, data availability was recognized as an important constraint during model development; consequently, CORINE is more appropriately regarded as a regional erosion-risk assessment approach than as a detailed process-based soil-loss model. For example, Everest and Özcan (2017) estimated erosion risk in the Dümrek Watershed using the CORINE method. They reported low, moderate, and high potential erosion risk over 66.80%, 22.25%, and 10.95% of the study area, respectively, whereas actual erosion risk was moderate over 38.67% and high over 61.33% of the area. They also identified slope and land cover as the factors exerting the strongest influence on erosion.

A key issue in applying the CORINE model at watershed or broader scales is the availability of all model inputs at sufficient spatial detail. Data availability has also been explicitly identified as an important limitation in studies concerning the development and application of the method. In particular, representing a spatially variable parameter such as surface stoniness by a single class when adequate data are unavailable may make model results dependent on the selected assumption. Accordingly, where the spatial distribution of stoniness cannot be determined, alternative conditions may be evaluated as separate scenarios to examine how uncertainty in this input is reflected in model outputs. This scenario-based treatment was adopted specifically in the present study. The standard CORINE method does not define an S1-S2 scenario procedure; therefore, this implementation constitutes a methodological distinction from conventional CORINE applications.

The aim of this study was to determine the spatial distribution of potential and actual soil erosion risk in the Erfelek Watershed, Sinop Province, Türkiye, using the CORINE model and GIS techniques. Soil texture, soil depth, slope, and land-cover characteristics were evaluated spatially. Because sufficiently detailed spatial data were not available to classify surface stoniness according to the 10% threshold used in the CORINE model, two alternative stoniness scenarios (S1 and S2) were developed. In addition to mapping potential and actual erosion risk across the watershed, the study therefore aimed to compare the influence of alternative assumptions regarding surface stoniness on model outputs.

2. MATERIALS AND METHODS

2.1. Study area

Sinop Province is located in northern Türkiye, in the central part of the Black Sea Region, between 41°12′-42°06′ N and 34°14′-35°26′ E. It is bordered by the Black Sea to the north, Kastamonu Province to the west, Çorum Province to the south, and Samsun Province to the southeast. The Erfelek Watershed, which constitutes the study area, is located in the northern part of Sinop Province and covers a total area of 52,281.07 ha (Figure 1). Sinop is influenced by the Black Sea climate and is characterized by humid and rainy conditions throughout the year. Owing to the strong maritime influence, seasonal temperature differences are relatively limited and coastal areas experience milder conditions. Precipitation is distributed throughout the year, with mean annual precipitation ranging from 679 to 1,077 mm. The mean annual temperature in central Sinop is approximately 14 °C, with mean temperatures of about 7 °C in winter and 20 °C in summer (Anonymous, 2026).

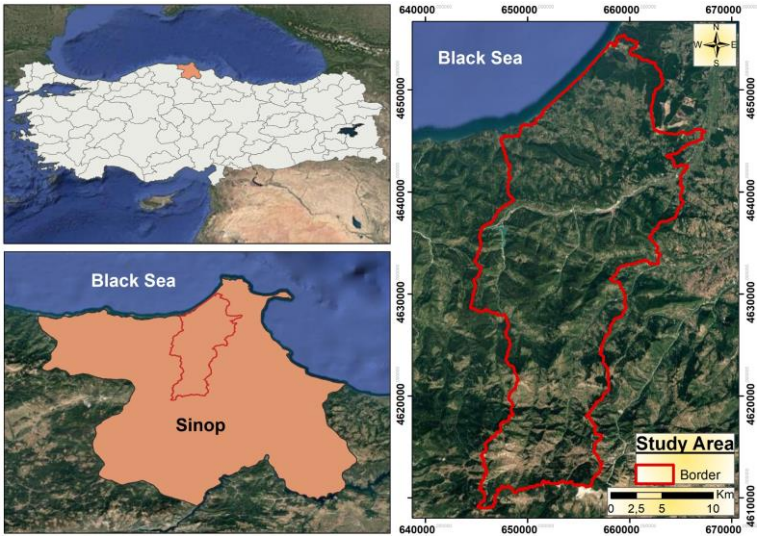

Figure 1. Location and spatial extent of the Erfelek Watershed within Sinop Province and Türkiye.

2.2. Preparation and Processing of Model Parameters

For preparation of the spatial data used in the CORINE model, the 52,281.07 ha Erfelek Watershed was adopted as the common study area. The model was implemented in a GIS environment to determine potential and actual soil erosion risk, using soil texture, soil depth, surface stoniness, slope, and land cover as the principal parameters (Figure 2).

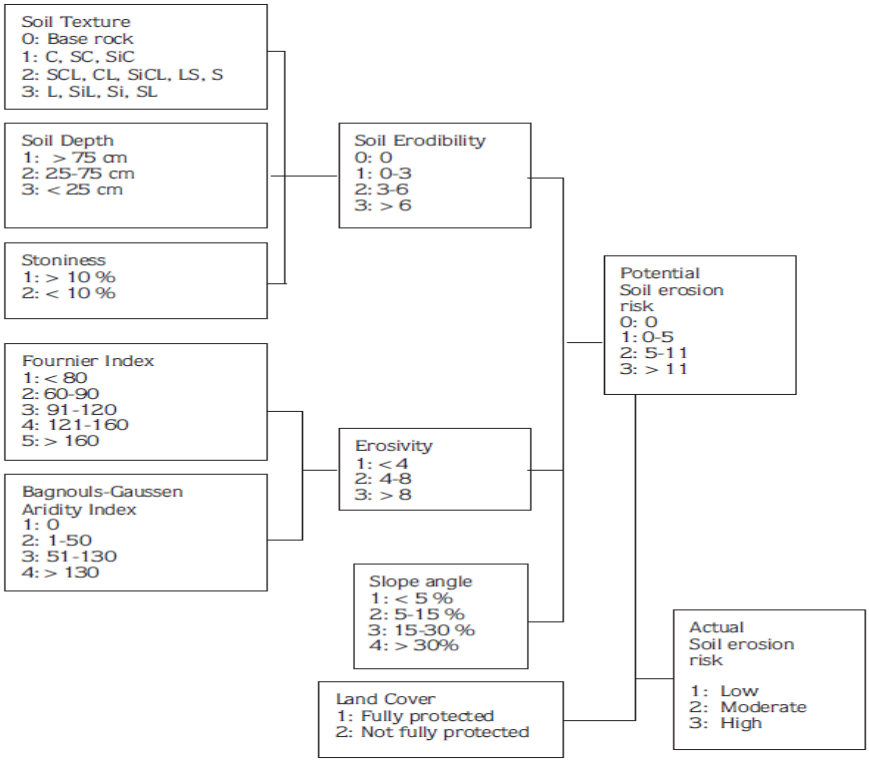

Figure 2. Flow diagram of the CORINE model.

Spatial layers of soil texture and soil depth were prepared using available soil data and information obtained from sampling points and were reclassified according to the CORINE methodology. Soil texture is an important property affecting aggregate stability and the detachment and transport of soil particles by rainfall and surface runoff. According to the CORINE classification approach, texture was evaluated in three classes: Class 1 represents soils with relatively low textural erodibility, Class 2 represents intermediate conditions, and Class 3 represents soils with relatively high textural erodibility (Figure ...). Soil depth, another property considered in determining soil erodibility, was also evaluated

in three classes: >75 cm, 25-75 cm, and <25 cm. Accordingly, soils deeper than 75 cm were assigned to Class 1, soils 25-75 cm deep to Class 2, and soils shallower than 25 cm to Class 3 (Figure ...).

Surface stoniness is another parameter used to determine soil erodibility in the CORINE model. However, because an adequate dataset describing the spatial distribution of surface stone cover was unavailable for the study area, two alternative scenarios, S1 and S2, were established for this parameter. Based on the 10% surface stone-cover threshold used in the CORINE approach, these scenarios represent two alternative model conditions rather than an observed spatial distribution of stoniness within the watershed. Thus, while all other model inputs were held constant, the effect of changing stoniness conditions on erosion-risk outputs was compared. Soil texture and depth classes were combined with the S1 and S2 stoniness scenarios to generate separate soil-erodibility layers for each scenario.

A 10 m spatial-resolution Digital Elevation Model (DEM) was used to represent the topographic factor. Slope values derived from the DEM as percentages were classified into four CORINE categories: <5%, 5-15%, 15-30%, and >30%. Combining soil erodibility and slope classes for each scenario produced the S1 and S2 potential erosion-risk layers (POT_S1 and POT_S2), which were subsequently classified as low, moderate, and high potential erosion risk.

In the final stage of the model, the protective effect of land cover against erosion was incorporated. CORINE Land Cover 2018 data were used, and land-cover classes were reclassified into two groups according to their soil-protection capacity: fully protected and not fully protected. Combining these land-cover protection classes with the S1 and S2 potential erosion-risk layers yielded actual erosion-risk layers (ACT_S1 and ACT_S2) for both scenarios. Actual erosion risk was also classified as low, moderate, or high. All spatial layers were harmonized to the same study-area boundary and spatial reference system before model analysis.

2.3.Soil texture

Soil texture influences both aggregate stability and the capacity of rainfall and surface runoff to detach and transport soil particles. In accordance with CORINE classification principles, soil texture information was converted into three relative erodibility classes. Class 1 represents soils with relatively low textural erodibility, Class 2 represents intermediate conditions, and Class 3 represents soils with relatively high textural erodibility. The resulting spatial distribution is presented in Figure 3. The map shows that Class 2 is widespread across the watershed, whereas Classes 1 and 3 occur in more spatially limited areas (Table 1).

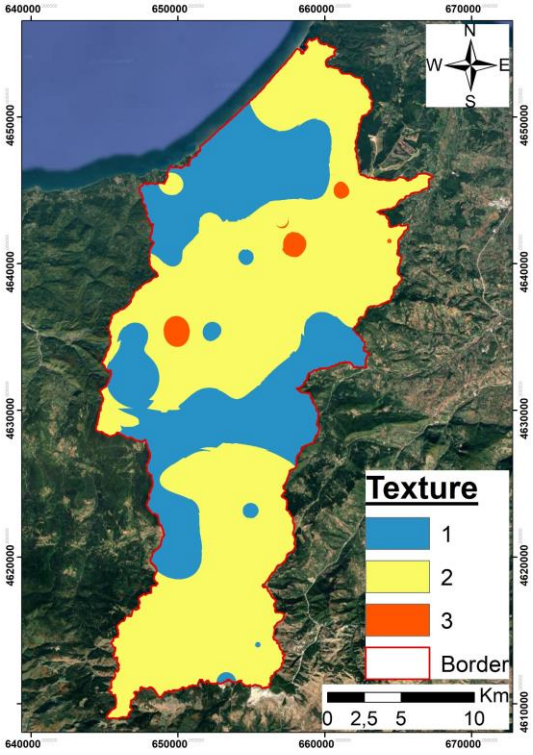

Figure 3. Spatial distribution of CORINE soil texture classes in the Erfelek Watershed.

Table 1. Areal and proportional distribution of CORINE soil texture classes.

Class	Texture	Area (ha)	Proportion (%)
1	Light-textured	16,918.87	32.36
2	Medium-textured	34,748.59	66.46
3	Heavy-textured	613.61	1.18
TOTAL		52,281.07	100.00

The distribution of soils in the Erfelek Watershed by texture class indicates that most of the study area consists of medium-textured soils (Class 2). This class covers 34,748.59 ha, corresponding to 66.46% of the total study area. Light-textured soils (Class 1) rank second, covering 16,918.87 ha (32.36%). Heavy-textured soils (Class 3) occupy only 613.61 ha (1.18%) and therefore have a very limited distribution within the watershed.

2.4. Soil depth

Soil depth affects erosion susceptibility because deep soil profiles generally have greater water-storage capacity, whereas shallow soils have a lower capacity to absorb and retain rainfall before surface runoff begins. Standard CORINE depth classes were adopted: soils deeper than 75 cm were assigned to Class 1, soils 25–75 cm deep to Class 2, and soils shallower than 25 cm to Class 3. The areal and proportional distribution of the soil depth classes is presented in Table 2, while their spatial distribution is shown in Figure 4. Moderately deep soils occupy a major part of the mapped watershed, whereas shallow soils occur in more localized areas.

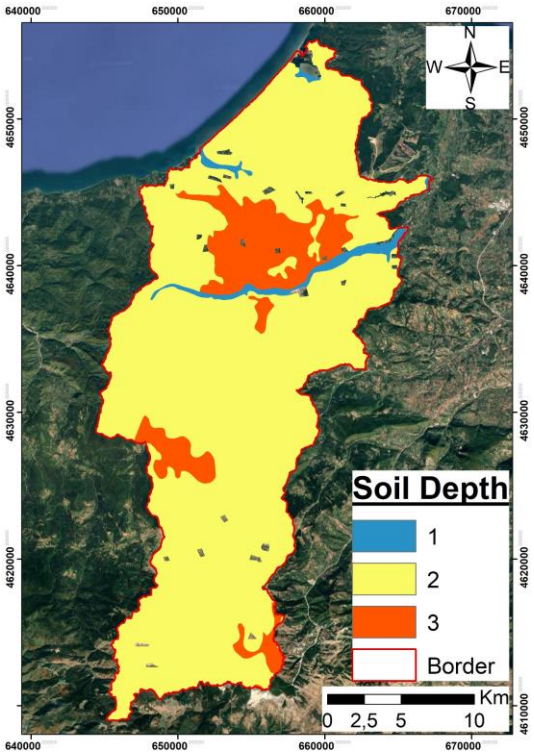

Figure 4. CORINE soil depth classes in the Erfelek Watershed.

Table 2. Areal and proportional distribution of CORINE soil depth classes in the Erfelek Watershed

Depth Class	Soil Depth	Erosion Susceptibility	Area (ha)	Proportion (%)
1	>75 cm	Low / less susceptible	1,047.66	2.00
2	25-75 cm	Moderately susceptible	45,037.18	86.15
3	<25 cm	Highly susceptible	6,196.23	11.85
TOTAL			52,281.07	100.00

The distribution of soils in the Erfelek Watershed by depth class shows that most of the study area consists of moderately deep soils (25-75 cm; Class 2). This class covers 45,037.18 ha, corresponding to 86.15% of the watershed. Shallow soils (<25 cm), which have greater susceptibility to erosion (Class 3), cover 6,196.23 ha (11.85%). In contrast, soils deeper than 75 cm, with lower erosion susceptibility

(Class 1), occupy only 1,047.66 ha (2.00%). This distribution demonstrates the clear dominance of moderately deep soils and the limited extent of deep soils with lower erosion susceptibility.

2.5. Surface stoniness scenarios

Surface stoniness is one of the components used to determine the CORINE soil-erodibility index. In the standard CORINE classification, areas with more than 10% surface stone cover are assigned a lower erodibility level because stones partially protect the soil surface from direct raindrop impact, whereas areas with less than 10% stone cover are considered to have limited protection. However, a sufficiently reliable dataset for mapping the spatial distribution of surface stoniness and classifying it according to the 10% threshold was unavailable for the study area. Therefore, two alternative scenarios (S1 and S2) were developed to evaluate the influence of stoniness conditions on CORINE model outputs. One scenario represents a surface stone-cover condition of >10%, while the other represents <10%; all other model parameters were held constant and potential erosion risk was calculated separately for each condition. In this way, the absence of detailed spatial stoniness data was addressed by evaluating model behavior under alternative conditions rather than by adopting a single assumption.

2.6. Slope classification

Slope was derived from a 10 m spatial-resolution Digital Elevation Model (DEM) and classified into four categories according to the CORINE methodology: <5%, 5-15%, 15-30%, and >30%. The areal and proportional distributions of the slope classes are presented in Table 3, and the slope map is shown in Figure 5.

Table 3. Areal and proportional distribution of slope classes.

Slope Class	Slope (%)	Area (ha)	Proportion (%)
1	0-5	3,002.28	5.74
2	5-15	9,932.20	19.00
3	15-30	17,387.87	33.26
4	>30	21,958.72	42.00
TOTAL		52,281.07	100.00

The distribution of slope classes in the Erfelek Watershed indicates that a substantial proportion of the study area consists of steep terrain. Areas with slopes >30% cover 21,958.72 ha (42.00%), while slopes of 15-30% account for 17,387.87 ha (33.26%). In comparison, slopes of 5-15% account for 19.00% of the watershed, and relatively flat areas with slopes of 0-5% account for only 5.74%. Thus, approximately 75.26% of the study area has slopes exceeding 15%, indicating a generally rugged topography. Because slope is a fundamental factor in determining potential erosion risk in the CORINE model, the extensive occurrence of steep terrain represents an important topographic control on the spatial distribution of erosion risk.

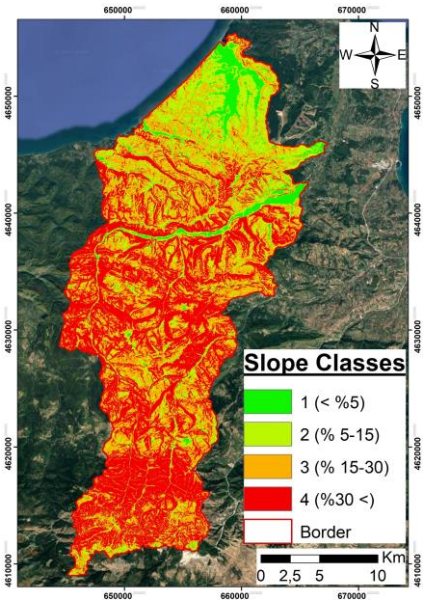

Figure 5. Slope classes of the study area.

The 15-30% and >30% slope classes are concentrated over broad, fragmented areas, particularly in the central and southern parts of the watershed. In contrast, the <5% and 5-15% slope classes are more evident in the northern part of the watershed and along valley floors.

2.7. Land-cover protection

CORINE 2018 land-cover data were divided into two categories according to their capacity to protect the soil surface. Areas with relatively continuous and protective cover were assigned to the fully protected class, whereas land-cover categories providing less protection were assigned to the not fully protected class.

This classification forms the principal distinction between potential and actual erosion risk. Potential risk reflects the inherent susceptibility before current land-cover protection is considered, whereas actual risk represents the erosion-risk class after existing land-cover conditions are incorporated into the model. The areal and proportional distribution of the land-cover protection classes is presented in Table 4, while their spatial distribution across the study area is shown in Figure 6.

Table 4. Areal and proportional distribution of land-cover protection classes.

Land-Cover Class	Protection Status	Area (ha)	Proportion (%)
1	Fully protected	31,535.52	60.32
2	Not fully protected	20,745.55	39.68
TOTAL		52,281.07	100.00

The distribution of land cover according to protection status shows that 31,535.52 ha (60.32%) of the Erfelek Watershed is classified as fully protected, whereas 20,745.55 ha (39.68%) is classified as not fully protected. The spatial distribution of the land-cover protection classes is presented in Figure 5.

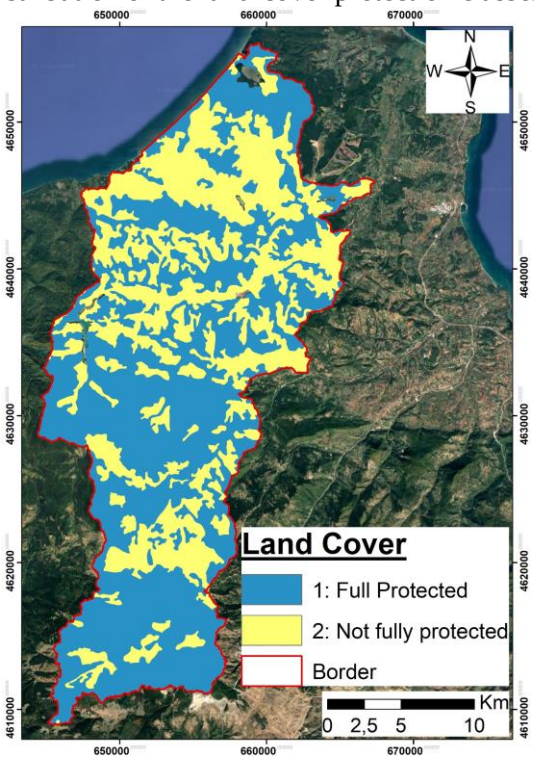

Figure 6. Spatial distribution of land-cover protection classes according to the CORINE model.

Of the study area, 60.32% (31,535.52 ha) is fully protected and 39.68% (20,745.55 ha) is not fully protected. Fully protected areas occupy broader areas particularly in the southern part of the watershed, whereas not fully protected areas show a more widespread and fragmented distribution in the northern and central parts. This difference in land cover influences the conversion of potential erosion risk into actual erosion risk in the CORINE model.

2.8. Mapping potential and actual erosion risk

Potential erosion risk was obtained by spatially integrating the soil-erodibility and topographic components of the CORINE framework.

The resulting potential erosion values were classified into low, moderate, and high risk categories. The procedure was performed separately for S1 and S2, producing two potential erosion-risk maps.
Actual erosion risk was subsequently assessed by combining the potential erosion-risk layer with the CORINE land-cover protection layer. This step was also performed separately for the two stoniness scenarios. Consequently, four principal outputs were obtained: potential erosion risk under S1, potential erosion risk under S2, actual erosion risk under S1, and actual erosion risk under S2.
The area occupied by each risk class was calculated in hectares and as a percentage of the common valid analysis area.

3. RESULTS AND DISCUSSION

3.1. Spatial characteristics of model inputs

The spatial input layers reveal substantial environmental heterogeneity across the Erfelek Watershed. The intermediate CORINE texture class is dominant, although extensive areas of the lower-erodibility class and smaller areas of the higher-erodibility class are also present. Soil depth shows a similarly heterogeneous distribution: moderately deep soils cover most of the watershed, while shallow soils are concentrated in specific areas. Dengiz et al. (2019) likewise demonstrated that land cover and soil properties such as texture and depth jointly shape the spatial variability of soil characteristics in a sub-humid watershed.
Topographic variability is particularly pronounced. The slope map shows broad areas of relatively gentle terrain in the northern part of the watershed, while steep and very steep slopes become increasingly prevalent toward the central and southern parts. The spatial pattern of the erosion-risk maps closely follows this topographic pattern, particularly under the less protective stoniness assumption.
This observation is consistent with previous CORINE applications in which topography was identified as an important control on erosion susceptibility. Khallouf et al. (2021) identified slope and land use/land cover as major determinants of spatial erosion risk, while Akbari et al. (2022) reported that potential risk is particularly sensitive to soil texture, slope, and soil depth. The extensive distribution of steep terrain in the Erfelek Watershed therefore represents an important source of potential erosion susceptibility.
A previous study in the Erfelek Dam Creek Watershed also reported that soil-erodibility indices varied substantially with both land-use type and parent material (Yilmaz et al., 2008). This finding supports the spatially explicit approach used in the present study rather than representing the watershed by a single generalized soil condition.

3.2. Potential soil erosion risk

Potential erosion-risk distributions differed markedly between the two stoniness scenarios. Under S1, 25,680.13 ha, corresponding to 49.12% of the common analysis area, was classified as low potential erosion risk. Moderate risk covered 26,494.47 ha (50.68%), whereas high risk was limited to only 106.47 ha (0.20%). Thus, approximately half of the watershed was classified as low risk and the other half as moderate risk, while high potential risk remained spatially very limited. The spatial distribution of potential soil erosion risk under the S1 scenario is shown in Figure 7.

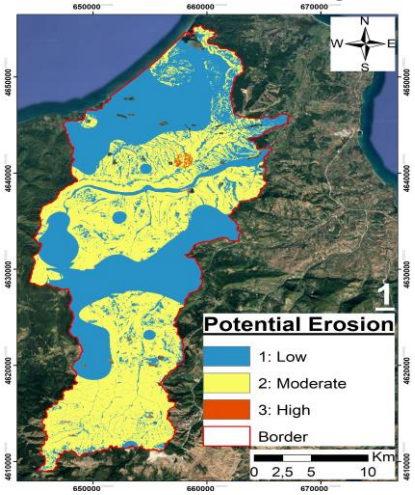

Figure 7. Distribution of potential soil erosion risk under Stoniness Scenario 1 (S1).

Under S2, the distribution changed substantially. The low-risk area decreased to 6,450.17 ha (12.34%), while the moderate-risk class increased to 30,299.78 ha (57.96%). The most notable change was the expansion of the high potential erosion-risk class to 15,531.12 ha, corresponding to 29.71% of the analysis area. The spatial distribution of potential soil erosion risk under the S2 scenario is shown in Figure 8. The areal and proportional distributions of potential and actual soil erosion-risk classes under the S1 and S2 scenarios are presented in Table 5.

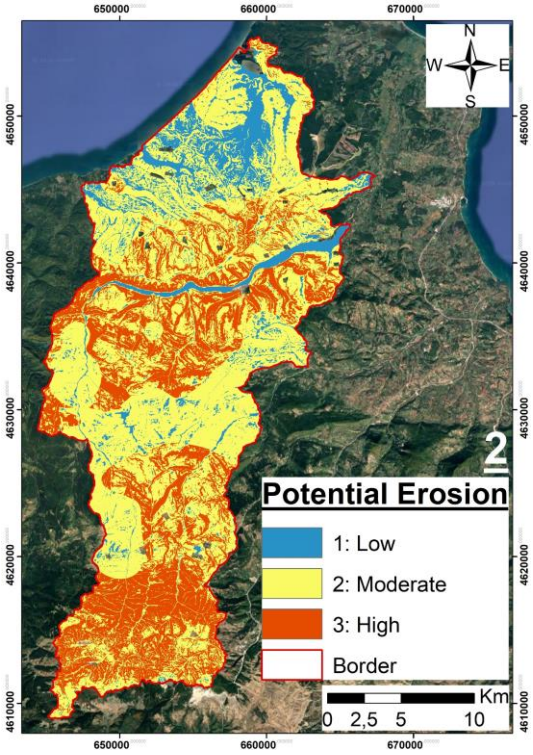

Figure 8. Distribution of potential soil erosion risk under Stoniness Scenario 2 (S2).

Table 5. Distribution of potential and actual soil erosion-risk classes.

Erosion Type	Scenario	Risk Class	Area (ha)	Proportion (%)
Potential	S1	Low	25,680.13	49.12
Potential	S1	Moderate	26,494.47	50.68
Potential	S1	High	106.47	0.20
Potential	S2	Low	6,450.17	12.34
Potential	S2	Moderate	30,299.78	57.96
Potential	S2	High	15,531.12	29.71
Actual	S1	Low	43,362.36	82.94
Actual	S1	Moderate	8,753.59	16.74
Actual	S1	High	165.12	0.32
Actual	S2	Low	24,068.05	46.04
Actual	S2	Moderate	24,103.07	46.10
Actual	S2	High	4,109.95	7.86

The transition from S1 to S2 reduced the proportion of low potential-risk areas by 36.78 percentage points and increased the high-risk proportion by approximately 29.50 percentage points. Accordingly, the area classified as high potential risk under S2 was substantially larger than under S1.

These results show that surface stoniness is an influential input in this application of the CORINE model. Because stoniness forms part of the multiplicative soil-erodibility component, a change in the assigned class propagates through the subsequent risk classification and may shift extensive areas from lower to higher risk categories.

This finding has an important methodological implication. If spatially explicit stoniness information were replaced by a single assumed value, the resulting erosion-risk map could appear definitive even

though it would represent only one of several plausible outcomes. The scenario approach makes this sensitivity visible and quantitatively comparable.

3.3. Actual soil erosion risk under S1

When land-cover protection was incorporated into the S1 potential-risk assessment, the proportion of low actual erosion risk increased markedly to 82.94%, corresponding to 43,362.36 ha. Moderate actual risk covered 8,753.59 ha (16.74%), while high actual risk was limited to 165.12 ha (0.32%). The spatial distribution of actual soil erosion risk under the S1 scenario is shown in Figure 9.

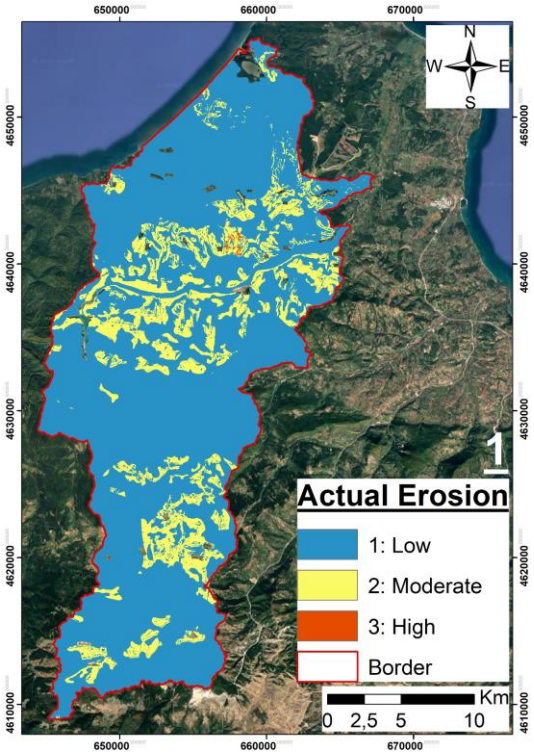

Figure 9. Distribution of actual soil erosion risk under Stoniness Scenario 1 (S1).

The most pronounced change relative to potential risk was the transition of extensive areas from the moderate category to the low actual-risk category. Low risk increased by approximately 33.82 percentage points, while moderate risk decreased by approximately 33.93 percentage points.

Although the high-risk proportion changed only slightly and remained below 0.4%, the overall spatial distribution clearly indicates a strong mitigating effect of existing land-cover conditions under S1. This distinction between potential and actual risk is a key advantage of the CORINE framework because it separates the inherent susceptibility of the landscape from the risk expressed under current vegetation and land-use conditions.

Similar effects of vegetation and land cover have been reported in previous CORINE studies. Aydın and Tecimen (2010) showed that land-use conditions altered the spatial distribution of actual erosion risk in the Elmalı Dam Watershed, while Yuksel et al. (2008) demonstrated the value of incorporating remotely sensed land-cover information into CORINE-based erosion mapping. These findings are also consistent with the general understanding that continuous vegetation cover reduces soil exposure to raindrop impact and surface runoff.

3.4. Actual soil erosion risk under S2

The protective effect of land cover was even more evident under S2. Under this less protective stoniness condition, the high potential-risk class covered 29.71% of the watershed. After land cover was incorporated into the model, the area of high actual risk decreased to 4,109.95 ha (7.86%). At the same time, low actual erosion risk increased from 12.34% at the potential-risk stage to 46.04%, while moderate actual risk accounted for 46.10% of the analysis area. The spatial distribution of actual soil erosion risk under the S2 scenario is shown in Figure 10.

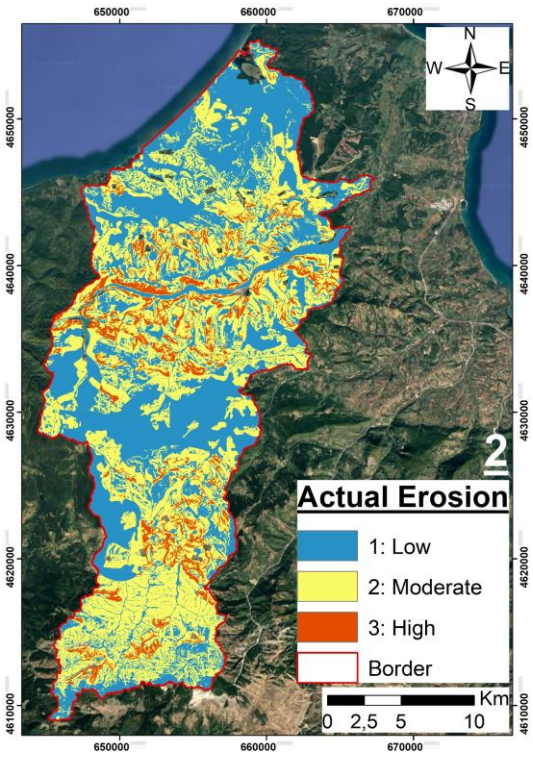

Figure 10. Distribution of actual soil erosion risk under Stoniness Scenario 2 (S2).

Thus, under S2, the high-risk proportion decreased by approximately 21.85 percentage points from potential to actual risk. Relative to its potential extent, the area assigned to the high-risk class declined by approximately three quarters after land-cover conditions were incorporated.

The maps show that most areas remaining in the moderate or high actual-risk classes coincide with steep terrain and less protective land cover. In contrast, extensive areas with high inherent susceptibility shift to lower actual-risk categories where vegetation provides stronger surface protection.

This behavior is consistent with the conceptual structure of the CORINE model and findings from other regions. Tayebi et al. (2017) emphasized that actual erosion risk is jointly controlled by potential erosion susceptibility and vegetation cover, while Akbari et al. (2022) demonstrated that vegetation plays an important role in determining actual risk even where inherent susceptibility related to soil and topography remains high.

3.5. Influence of stoniness scenarios

Comparison of the two scenarios developed for the stoniness parameter showed that alternative surface-stoniness conditions exerted a strong influence on both potential and actual erosion-risk maps.

For potential risk, the proportion of the watershed classified as high risk was only 0.20% under S1 but reached 29.71% under S2. Moderate potential risk ranged from 50.68% to 57.96%, while low potential risk ranged from 12.34% to 49.12%. The scenario effect remained evident after land cover was incorporated: high actual erosion risk ranged from 0.32% to 7.86%, moderate actual risk from 16.74% to 46.10%, and low actual risk from 46.04% to 82.94%. These ranges should not be interpreted as conventional statistical confidence intervals; rather, they represent the sensitivity of the categorical CORINE output to two alternative assumptions for an input parameter for which detailed spatial data were unavailable. In this sense, the analysis provides a practical range of possible erosion-risk classifications under the two modeled conditions.

Another important finding is that land cover moderated part of the difference associated with high-risk classification. The difference in high potential risk between S1 and S2 was approximately 29.5 percentage points, whereas the corresponding difference between high actual-risk classes was approximately 7.5 percentage points. Thus, existing surface-cover protection substantially limited the extent to which differences in the stoniness condition were reflected in the highest actual-risk category.

The differences between the two scenarios also indicate the value of obtaining more spatially detailed stoniness information in future CORINE applications. Field observations or remote-sensing-supported

surveys of surface stoniness could allow the scenario layers to be refined into a spatially differentiated stoniness layer and thereby further strengthen erosion-risk assessment.

3.6. Implications for watershed management

Erosion-risk maps are useful not because they directly quantify annual soil loss, but because they qualitatively identify where combinations of climate, soil properties, topography, and land-cover conditions create relatively greater vulnerability. They can therefore provide rapid spatial information to support decision makers and planners in prioritizing areas for further assessment and management.

Under the more conservative S2 assumption used in this CORINE application, areas of high potential risk are concentrated particularly on steep terrain in the central and southern parts of the watershed. Although land-cover protection substantially reduces the extent of high actual erosion risk, some spatially coherent risk zones remain. These areas may be appropriate targets for more detailed field investigations before erosion-control measures are prioritized. The results also emphasize the importance of maintaining existing protective land cover. Areas currently showing low actual risk may nevertheless have moderate or high inherent susceptibility; removal or degradation of protective vegetation could expose the underlying potential erosion risk. Therefore, comparison of potential and actual risk maps provides more management-relevant information than a single erosion-risk map alone.

4. CONCLUSIONS AND RECOMMENDATIONS

In this study, potential and actual soil erosion risk in the Erfelek Watershed was spatially assessed using the CORINE model and GIS techniques. Soil properties, topography, and land-cover data were integrated within the model, while surface stoniness was represented through two alternative scenarios under the available data conditions. This approach enabled the effects of different surface conditions on erosion-risk classes to be evaluated comparatively.

The topographic characteristics of the watershed indicate conditions that are important for erosion assessment. Approximately 75.26% of the study area has slopes greater than 15%, demonstrating the extensive occurrence of steep and very steep terrain. Nevertheless, the spatial distribution of erosion risk cannot be explained by slope alone; soil properties, surface conditions, and land cover need to be considered together.

Scenario analysis showed that potential erosion risk was concentrated mainly in the low and moderate classes under S1, whereas moderate- and high-risk areas became more prominent under S2. High potential erosion risk accounted for 0.20% under S1 and 29.71% under S2. After the protective effect of land cover was incorporated, high actual erosion risk accounted for 0.32% under S1 and 7.86% under S2. These differences demonstrate that alternative surface conditions can influence the spatial distribution of erosion risk estimated by the CORINE model. The scenario-based approach therefore enabled the model to be evaluated under two plausible conditions where detailed spatial information on surface stoniness was unavailable.

Incorporating land cover produced marked changes in the distribution of potential and actual erosion risk. The finding that 60.32% of the watershed belongs to the fully protected land-cover class highlights the importance of surface protection, particularly in erosion-susceptible areas. This result indicates that maintaining existing vegetation and land cover is an important component of erosion-risk reduction and sustainable watershed management.

Overall, integrating the CORINE model with GIS enabled erosion risk in the Erfelek Watershed to be mapped spatially and the effects of alternative surface conditions on model outputs to be compared. The use of two surface-stoniness scenarios maintained the applicability of the model under the available data conditions while allowing the results to be assessed under different plausible conditions. The resulting risk maps can provide useful spatial information for identifying erosion-susceptible areas, prioritizing soil and water conservation measures, protecting land cover, and planning sustainable land management at the watershed scale.

ÖZET
Kuraklık, tahıl üretimini sınırlandıran önemli abiyotik stres faktörlerinden biri olup etkileri yalnızca tane verimindeki azalmalarla sınırlı değildir. Tohumluk üretimi sırasında meydana gelen su noksanlığı; döllenme, embriyo ve endosperm gelişimi, asimilatların gelişmekte olan tohumlara taşınması, depo maddelerinin birikimi ve olgunlaşma süreçlerini etkileyerek elde edilen tohumluğun fiziksel ve fizyolojik kalitesinde değişikliklere neden olabilmektedir. Özellikle çiçeklenme, tohum gelişimi ve tane doldurma dönemlerinde meydana gelen kuraklık, tohum iriliği, ağırlığı ve dolgunluğu gibi fiziksel kalite özelliklerini olumsuz etkileyebilmektedir. Bunun yanında, çimlenme dönemindeki düşük su potansiyeli tohumun su alımını ve metabolik aktivitesini sınırlandırarak depo maddelerinin mobilizasyonunu, çimlenmeyi ve erken fide gelişimini baskılayabilmektedir. Kuraklık koşullarında çimlenme oranı ve hızında azalma, çimlenmenin gecikmesi, vigor kaybı ile kök ve sürgün gelişiminde gerileme görülebilmektedir. Tohumluk kalitesinde meydana gelen bu değişimler, ekim sonrasında homojen çıkışın sağlanmasını ve bitkilerin erken dönemde başarılı bir şekilde gelişmesini de etkileyebilmektedir. Bu nedenle kuraklığın tohumluk üzerindeki etkilerinin yalnızca hasat edilen tohumların fiziksel özellikleri üzerinden değerlendirilmesi yeterli değildir. Bununla birlikte, bu etkilerin büyüklüğü tahıl türü, genotip, stresin şiddeti ve süresi ile meydana geldiği gelişme dönemine bağlı olarak önemli ölçüde değişmektedir. Buğday, arpa, mısır, çeltik ve sorgumda yapılan çalışmalar, kuraklığın tohumluk ve erken gelişim özellikleri üzerinde farklı etkiler oluşturduğunu ve genotipler arasında belirgin varyasyon bulunduğunu ortaya koymaktadır. Tohumluk üretimi sırasında meydana gelen kuraklığın elde edilen tohumların sonraki çimlenme ve fide performansına yansıması, sürdürülebilir tahıl üretimi açısından ayrıca önem taşımaktadır. Bu nedenle kuraklık toleransının değerlendirilmesinde yalnızca tane veriminin değil; tohum ağırlığı, çimlenme, vigor, tarla çıkışı ve erken fide gelişimi gibi özelliklerin birlikte ele alınması gerekmektedir. Sonuç olarak, değişen iklim koşullarında tahıllarda yüksek tane veriminin yanı sıra kuraklık koşullarında fiziksel ve fizyolojik kalitesini koruyabilen kaliteli tohumluk üretiminin sürdürülmesi de önem taşımaktadır.
Anahtar kelimeler: Kuraklık, tahıllar, tohumluk kalitesi, çimlenme.

ABSTRACT
Drought is one of the major abiotic stress factors limiting cereal production, and its effects are not restricted to reductions in grain yield. Water deficit during seed production may affect fertilization, embryo and endosperm development, assimilate translocation to developing seeds, reserve accumulation, and maturation, thereby causing changes in the physical and physiological quality of the resulting seed. Drought occurring particularly during flowering, seed development, and grain filling may adversely affect physical quality traits such as seed size, weight, and plumpness. In addition, low water potential during germination may restrict seed water uptake and metabolic activity, thereby limiting reserve mobilization, germination, and early seedling development. Under drought conditions, reductions in germination percentage and rate, delayed germination, loss of vigor, and restricted root and shoot growth may occur. These changes in seed quality may also affect uniform emergence and successful early plant development after sowing. Therefore, evaluating the effects of drought on seeds solely on the basis of the physical characteristics of harvested seed is insufficient. Nevertheless, the magnitude of these effects varies considerably depending on cereal species, genotype, stress intensity and duration, and the developmental stage at which the stress occurs. Studies conducted on wheat,

barley, maize, rice, and sorghum have demonstrated that drought has different effects on seed quality and early developmental traits and that considerable variation exists among genotypes. The effects of drought occurring during seed production on the subsequent germination and seedling performance of the resulting seed are also of particular importance for sustainable cereal production. Therefore, the assessment of drought tolerance should consider not only grain yield but also seed weight, germination, vigor, field emergence, and early seedling development. In conclusion, under changing climatic conditions, maintaining the production of high-quality seed capable of preserving its physical and physiological quality under drought conditions is important in addition to sustaining high grain yield in cereals.
Keywords: Drought, cereals, seed quality, germination.

GİRİŞ

Tahıllar, diğer kültür bitkisi gruplarına kıyasla dünya genelinde geniş alanlarda yetiştirilmeleri ve insan beslenmesinde önemli bir enerji kaynağı olmaları sebebiyle temel gıda kaynakları arasında önemli bir yere sahiptir (Sarwarve ark., 2013). Bununla birlikte, tahıl üretimi çevresel stres faktörlerinden önemli ölçüde etkilenmektedir. Küresel iklim değişikliğinin kültür bitkilerinin verim düzeyleri üzerinde önemli etkiler oluşturabileceği ve gıda güvenliğinin sağlanabilmesi açısından ele alınması gereken temel sorunlardan biri olduğu kabul edilmektedir (Tripathi ve ark., 2016; Howden ve ark., 2007). Özellikle iklim değişikliğine bağlı olarak yağış rejimlerindeki düzensizlikler, sıcaklık artışları ve kurak dönemlerin sıklık ve şiddetindeki artış, tarımsal üretimin sürdürülebilirliği açısından önemli bir tehdit oluşturmaktadır. Kuraklık; bitkilerde su ilişkilerini, fotosentezi, karbon metabolizmasını, besin elementi alımını, hormonal dengeyi ve kaynak-havuz ilişkilerini etkileyerek büyüme ve gelişmeyi sınırlandırmaktadır (Bapela ve ark., 2022; Pandey ve ark., 2022; Wu ve Yang, 2024).

Kuraklık stresi, bitkilerin büyüme ve gelişiminin birçok yönünü olumsuz etkileyen önemli bir sınırlayıcı faktör olarak kabul edilmektedir (Alghbari ve Ihsan, 2018; Kapoor ve ark., 2020). Tohum çimlenmesi ve sağlığı, koleoptil uzunluğu ve yaprak alanı, bitkinin gelişimi açısından büyük önem taşımaktadır. Tohum çimlenmesi, kuraklık stresine karşı duyarlılık gösteren büyüme ve gelişme süreçlerinin başında gelmektedir (Kapoor ve ark., 2020). Erken vejetatif dönemde su noksanlığına maruz kalan bitkilerde, çimlenme oranındaki azalmanın yanı sıra yapraklarda solgunluk da belirgin bir stres belirtisi olarak ortaya çıkmaktadır. Su yetersizliği ayrıca sürgün uzunluğu ve hipokotil yaş ağırlığında azalmaya yol açarak bitki büyümesini olumsuz etkilemektedir (Abobatta, 2019). Bunun yanında, toprağın kurumasıyla birlikte bitki tarafından besin elementlerinin alımının kısıtlanması, tomurcuk ve çiçek oluşumunun sekteye uğramasına neden olabilmektedir (Abobatta, 2019; Kapoor ve ark., 2020).

Buğdayda başaklanma sonrasında meydana gelen kuraklığın tane dolum hızı üzerindeki etkisinin sınırlı olduğu, ancak tane dolum süresini kısalttığı ve bunun sonucunda olgunluk dönemindeki tane kuru ağırlığını azalttığı bildirilmiştir (Wardlaw ve Willenbrink, 2000). Arpada ise kuraklık stresi; kardeş sayısı, başak sayısı, bitki başına tane sayısı ve bireysel tane ağırlığında azalmaya neden olarak tane verimini düşürmektedir. Çiçeklenme sonrası dönemde meydana gelen kuraklık stresinin, stresin şiddetinden bağımsız olarak tane verimi üzerinde olumsuz etkiler oluşturduğu bildirilmiştir (Samarah, 2005; Alghbari ve Ihsan, 2018).

KURAKLIK VE TOHUM GELİŞİMİ

Yetersiz su mevcudiyeti, bitki bünyesinde kısa sürede su noksanlığının ortaya çıkmasına neden olmaktadır. Buna bağlı olarak gelişen dehidrasyon; bitkinin metabolizmasını, büyüme ve gelişmesini ve morfolojik yapısını önemli ölçüde etkilemektedir. Su noksanlığı koşullarında fizyolojik süreçlerde meydana gelen kapsamlı değişimler, büyümenin yavaşlamasına veya tamamen durmasına yol açarak verim kararlılığını tehdit etmektedir (Anjum ve ark., 2011). Tarla koşullarında kuraklığa bağlı verim kayıpları genellikle %30–90 arasında değişmekte ve bu kayıpların düzeyi bitki türlerine göre önemli farklılıklar göstermektedir (Hussain ve ark., 2019).

Birçok kültür bitkisinde tohum ve meyveler, hasat edilen temel veya tek ekonomik ürünü oluşturmaktadır (Şekil 3). Bu nedenle tozlanma, tohum tutumu ve meyve gelişimi, ürün veriminin oluşumunda belirleyici rol oynayan kritik gelişme süreçleridir. Hayvanlar aracılığıyla tozlanan çiçeklerde tozlanma başarısı, polen miktarı ve nektar mevcudiyetine bağlı olup, sera koşullarında yürütülen bir çalışmada her iki özelliğin de kuraklık stresi altında azaldığı belirlenmiştir (Waser ve Price, 2016). Tozlanmayı izleyen süreçte polen tüpü gelişiminin de kuraklık koşullarında baskılandığı ve bu

durumun karbonhidrat mobilizasyonundaki azalmayla ilişkili olabileceği bildirilmiştir (Hu ve ark., 2019). Kuraklık stresi altında gelişmekte olan taneler arasında sınırlı karbon kaynakları için meydana gelen rekabet, tohumların gelişimini tamamlayamamasına neden olabilmekte; kontrollü tozlanma uygulamalarının ise bu kayıpları azaltabildiği bildirilmektedir (Shen ve ark., 2020). Bunun yanı sıra, tozlanma ve tohum tutumunun başarısız olması veya floem yoluyla taşınan asimilatlar için oluşan rekabet, çiçek dökülmesine neden olabilmektedir (Patrick ve Stoddard, 2010).

Başarılı bir tozlanma ve tohum tutumunun ardından, tohum dolumu ve meyve gelişiminin sürdürülebilmesi asimilatların gelişmekte olan organlara etkin biçimde taşınmasına bağlıdır. Kuraklık koşullarında fotosentezin baskılanmasına bağlı olarak asimilat mevcudiyetinin azalması ve asimilatların bitki organları arasındaki dağılımının değişmesi, bitkinin kuraklık stresine karşı büyüme tepkisinin belirlenmesinde önemli rol oynamaktadır. Kuraklık altında asimilat dağılımının yeniden düzenlenmesine, karbonhidrat metabolizması ve taşınımında görev alan genlerin ekspresyonundaki değişimler eşlik etmektedir (Dietz ve ark., 2021).

KURAKLIĞIN FİZİKSEL VE FİZYOLOJİK TOHUMLUK KALİTESİNE ETKİLERİ

Kuraklık nedeniyle fotosentez ve asimilat taşınımının sınırlandırılması, özellikle tane doldurma döneminde kuru madde birikiminin azalmasına yol açabilmektedir. Bunun sonucunda tohum iriliği, tane ağırlığı ve dolgunluğu azalabilmekte; cılız veya buruşuk tohumların oranı artabilmektedir (Barnabás ve ark., 2008; Sehgal ve ark., 2018; Sallam ve ark., 2019). Gelişmekte olan tohumdaki rezerv birikiminin değişmesi, sonraki çimlenme ve fide gelişimi için kullanılabilecek kaynak miktarını da etkileyebilir.

Kuraklık, tohumluğun fizyolojik kalitesini de doğrudan veya dolaylı olarak etkileyebilmektedir. Düşük su potansiyeli tohumun su alımını sınırlandırarak imbibisyonu ve metabolik aktivasyonu geciktirmekte; depo maddelerinin mobilizasyonu ve embriyonik eksenin gelişimini baskılayabilmektedir. Bunun sonucunda çimlenme yüzdesi ve hızı, vigor, normal fide oranı, kök ve sürgün gelişimi azalabilmektedir (Soltani ve ark., 2006; Finch-Savage ve Bassel, 2016; Thabet ve ark., 2020; Ahmed ve ark., 2025).

Buğdayda artan ozmotik stres altında çimlenme, kök ve sürgün uzunluğu, fide biyokütlesi ve vigor indeksinin azaldığı bildirilmiştir (Ahmed ve ark., 2025). Benzer şekilde mısırda kuraklık çimlenme oranı ve enerjisi ile radikula ve koleoptil gelişimini baskılamıştır (Du ve ark., 2025). Sorgumda ise çimlenme ve fide dönemindeki kuraklık toleransı bakımından genotipler arasında geniş varyasyon bulunduğu belirlenmiştir (Wang ve ark., 2025).

TAHIL TÜRLERİNİN KURAKLIK STRESİNE TEPKİLERİ

Kuraklığa verilen tepki türler arasında farklılık gösterdiği gibi aynı tür içerisindeki genotipler arasında da önemli varyasyon göstermektedir. Bu nedenle kuraklığın tohumluk kalitesi üzerindeki etkileri değerlendirilirken tür × genotip × stres şiddeti × stres süresi × gelişme dönemi etkileşimi dikkate alınmalıdır (Sallam ve ark., 2019; Prasad ve ark., 2021; Seleiman ve ark., 2021).

Tablo 1. Tahıl Türlerinin Tohumluk ve Erken Gelişim Döneminde Kuraklığa Tepkileri

Tahıl	Kuraklığın Uygulandığı Dönem	Değerlendirilen Özellikler	Başlıca Etkiler	Kaynak
Buğday (*Triticum aestivum* L.)	Çimlenme ve fide dönemi	Çimlenme, vigor, kök-sürgün gelişimi, biyokütle	Çimlenme, vigorda ve kök-sürgün gelişimi azalma; genotipik farklılık	Ahmed ve ark. (2025)
Arpa (*Hordeum* spp.	Tohum gelişimi dönemi	Tane verimi, irilik, vigor, metabolik özellikler	Tane veriminde azalma; metabolik değişimler; genotipik farklılık	Nagel ve ark., (2022)
Mısır (*Zea mays* L.)	Çimlenme ve fide dönemi	Çimlenme, radikula-koleoptil gelişimi, biyokütle	Çimlenme, radikula-koleoptil gelişimi ve biyokütlede azalma	Du ve ark. (2025)
Çeltik (*Oryza sativa* L.)	Çiçeklenme ve tohum oluşum dönemi	Çimlenme, tane kalitesi, depolama ömrü	Erken kuraklıkta kalite kaybı, çimlenme ve	Rahman ve Ellis (2019)

			depolama ömründe azalma	
Sorgum (Sorghum bicolor L.)	Çimlenme ve fide dönemi	Çimlenme ve vigor	Çimlenme ve vigor özelliklerinde değişim; belirgin genotipik varyasyon	Wang ve ark. (2025)

Kuraklığın tohumluk ve erken gelişim özellikleri üzerindeki etkileri, stresin meydana geldiği gelişme dönemi ve genotipe bağlı olarak değişmektedir (Tablo 1). Arpa ve çeltikte yapılan çalışmalarda, tohum üretimi sırasında meydana gelen kuraklık stresinin elde edilen tohumların özelliklerini etkilediği belirlenmiştir (Rahman ve Ellis, 2019; Nagel ve ark., 2022). Buna karşılık, buğday, mısır ve sorgumda yapılan çalışmalarda tohumların kuraklık koşullarındaki çimlenme ve erken fide gelişimi bakımından belirgin genotipik farklılıklar gösterdiği ortaya konulmuştur (Ahmed ve ark., 2025; Du ve ark., 2025; Wang ve ark., 2025).

Bu sonuçlar, kuraklık toleransının yalnızca tane verimi veya tek bir çimlenme özelliği üzerinden değerlendirilmemesi gerektiğini göstermektedir. Tohumluk üretimi sırasında maruz kalınan stres ile elde edilen tohumların sonraki performansı arasındaki ilişkinin ortaya konulması, sürdürülebilir tohumluk üretimi açısından önemli bir araştırma alanıdır.

SONUÇ

Kuraklık, tahıllarda yalnızca tane verimini değil, elde edilen tohumluğun fiziksel ve fizyolojik kalitesini de etkileyebilmektedir. Özellikle çiçeklenme, tohum gelişimi ve tane doldurma dönemlerinde meydana gelen su noksanlığı; embriyo ve endosperm gelişimini, asimilat taşınımını ve depo maddelerinin birikimini etkileyerek tohumluk kalitesinde değişikliklere neden olabilmektedir. Bunun yanında, çimlenme dönemindeki su noksanlığı tohumun su alımını ve metabolik süreçleri sınırlandırarak çimlenme, vigor ve erken fide gelişimini olumsuz etkileyebilmektedir.

Kuraklığın tohumluk kalitesi üzerindeki etkisinin büyüklüğü; tahıl türü, genotip, stresin şiddeti ve süresi ile meydana geldiği gelişme dönemine bağlı olarak değişmektedir. Bu nedenle kuraklık toleransının değerlendirilmesinde yalnızca tane veriminin değil; tohum ağırlığı, çimlenme, vigor, tarla çıkışı ve erken fide gelişimi gibi özelliklerin de birlikte ele alınması önem taşımaktadır. Ayrıca tohumluk üretimi sırasında meydana gelen kuraklık ile elde edilen tohumların sonraki çimlenme ve fide performansı arasındaki ilişkinin farklı tahıl türleri ve genotiplerde daha ayrıntılı olarak araştırılması gerekmektedir.

Sonuç olarak, değişen iklim koşullarında tahıl üretiminin sürdürülebilirliği açısından yalnızca yüksek tane veriminin korunması yeterli değildir. Kuraklık koşullarında fiziksel ve fizyolojik kalitesini koruyabilen, yüksek çimlenme ve vigor gösteren ve güçlü erken fide gelişimi sağlayabilen kaliteli tohumlukların üretimi, ıslah ve yetiştirme stratejilerinin temel hedeflerinden biri olmalıdır.

ÖZET
Buğday, Anadolu'nun tarımsal geçmişi, beslenme kültürü ve bitkisel genetik kaynakları içerisinde özel bir yere sahiptir. Anadolu'nun farklı agroekolojik bölgelerinde uzun yıllar boyunca çiftçiler tarafından yetiştirilen yerel buğday popülasyonları, doğal seleksiyon ve çiftçi seleksiyonunun ortak etkisi altında şekillenmiş geniş bir genetik ve fenotipik çeşitlilik barındırmaktadır. Günümüzde yaygın olarak "ata tohumu" olarak da ifade edilen bu geleneksel materyaller; belirli çevrelere uzun süreli uyum göstermeleri, genetik çeşitliliklerini korumaları ve farklı biyotik ve abiyotik streslere karşı önemli varyasyon taşımaları nedeniyle sürdürülebilir tarım açısından yeniden önem kazanmaktadır. İklim değişikliğine bağlı olarak kuraklık ve sıcaklık streslerinin şiddetlenmesi, su kaynaklarının azalması, toprak verimliliğinin bozulması ve tarımsal girdi maliyetlerinin artması, daha az dış girdiye gereksinim duyan üretim sistemlerinin geliştirilmesini gerekli kılmaktadır. Gübre, sulama, pestisit ve enerji kullanımının sınırlandırıldığı düşük girdili tarım sistemlerinde yalnızca yüksek verim potansiyeli değil; su ve besin elementlerinin etkin kullanımı, çevresel streslere tolerans, hastalık direnci, yabancı otlarla rekabet, verim kararlılığı ve ürün kalitesi gibi özellikler de önem taşımaktadır. Anadolu yerel buğdayları özellikle kuraklık, düşük sıcaklık, sınırlı toprak verimliliği ve değişken yetiştirme koşullarına adaptasyon bakımından önemli bir genetik çeşitlilik sunmaktadır. Bununla birlikte yerel çeşitlerin modern çeşitlerden her koşulda daha üstün olduğunun kabul edilmesi doğru değildir. Modern çeşitler özellikle optimum yetiştirme koşullarında yüksek tane verimi, yatmaya dayanıklılık ve agronomik üniformite bakımından önemli avantajlara sahip olabilmektedir. Bu nedenle Anadolu yerel buğdaylarının gelecekteki önemi, doğrudan üretimde kullanılmalarının yanı sıra taşıdıkları adaptif özelliklerin modern çeşitlerin yüksek verim potansiyeliyle bütünleştirilmesinde yatmaktadır. Yerel çeşitlerin ve ata tohumlarının korunması, kapsamlı biçimde karakterize edilmesi ve modern ıslah programlarında etkin olarak değerlendirilmesi; düşük girdili, kaynak kullanım etkinliği yüksek, çevresel değişkenliklere uyum sağlayabilen ve iklim değişikliğine daha dayanıklı buğday üretim sistemlerinin geliştirilmesine önemli katkılar sağlayabilir.
Anahtar kelimeler: Buğday, yerel çeşit, sürdürülebilir tarım

ABSTRACT
Wheat holds a prominent position in the agricultural history, food culture, and plant genetic resources of Anatolia. Local wheat populations cultivated by farmers for generations across the diverse agroecological regions of Anatolia harbor substantial genetic and phenotypic diversity shaped by the combined effects of natural and farmer-mediated selection. These traditional genetic resources, commonly referred to as "ancestral seeds" in Türkiye, have recently regained considerable importance for sustainable agriculture due to their long-term adaptation to specific environments, maintenance of genetic diversity, and extensive variation in responses to various biotic and abiotic stresses. The increasing severity of drought and heat stresses associated with climate change, declining water availability, deterioration of soil fertility, and rising agricultural input costs have intensified the need for production systems that rely on fewer external inputs. In low-input agricultural systems, where fertilizer, irrigation, pesticide, and energy use is reduced, emphasis is placed not only on high yield potential but also on efficient water and nutrient utilization, tolerance to environmental stresses, disease resistance,

competitive ability against weeds, yield stability, and end-use quality. Anatolian wheat landraces represent a valuable reservoir of genetic diversity, particularly for adaptation to drought, low temperatures, limited soil fertility, and fluctuating growing conditions. Nevertheless, landraces should not be assumed to outperform modern cultivars under all environmental and management conditions. Modern cultivars may provide substantial advantages in grain yield, lodging resistance, and agronomic uniformity, particularly under optimal growing conditions. Therefore, the future importance of Anatolian wheat landraces lies not only in their direct use in agricultural production but also in integrating their adaptive traits with the high-yield potential of modern cultivars. The conservation, comprehensive characterization, and effective utilization of landraces and ancestral genetic resources in modern breeding programs could make a significant contribution to developing low-input, resource-efficient wheat production systems capable of adapting to environmental variability and increasing resilience to climate change.
Keywords: Wheat, landrace, sustainable agriculture

GİRİŞ

Buğday, insanlık tarihinin en eski kültür bitkilerinden biri olup kültüre alınması yaklaşık 12.000 yıl önce başlamıştır ve insanlık tarihinde bir dönüm noktası olarak kabul edilmektedir (Tanno ve Willcox, 2006). Bereketli Hilal'in kuzey kesiminde yer alan Anadolu'da yerleşik hayata geçiş ve tarımın başlaması, buğdayın kültüre alınmasıyla eş zamanlı gerçekleşmiştir (Atar, 2017). Bu tarihsel süreç, Anadolu'da gerek ekmeklik gerekse makarnalık buğdaylarda zengin genetik ve fenotipik çeşitliliğin oluşmasında önemli pay sahibi olmuştur (Karagöz ve Zencirci, 2005; Baloch ve ark., 2017).

Yerel çeşitler, tarihsel bir kökeni olan, kendine özgü bir kimliğe sahip, genellikle genetik çeşitlilik gösteren ve yerel koşullara uyum sağlamış, ayrıca çiftçilerin tohum seçimi ve tarla yönetimi uygulamalarıyla ve bilgi birikimiyle ilişkilendirilen, kültür bitkilerinin dinamik popülasyonları olarak tanımlanmaktadır (Azez ve ark., 2018). Yerel iklim koşullarına adapte olmuş, zaman süzgecinden geçerek kuşaktan kuşağa aktarılarak varlığını sürdürmüş ve çiftçilerin ihtiyaç duydukları tohumluğu üretilebilmelerine olanak sağlayan yerel çeşitler, sürdürülebilir tarımın ekolojik, ekonomik ve sosyo-kültürel düzeylerinde önemli avantajlar sağlamaktadır (Kayış ve ark., 2025).

Yerel çeşitler, bünyelerinde barındırdıkları genotipik çeşitlilik nedeniyle çok sayıda özellik bakımından geniş bir varyasyon sergileyebilmektedir. Bu varyasyon, söz konusu çeşitlerin yetiştirildikleri çevre koşullarında doğal seleksiyonun yanı sıra, sınırlı ölçüde geleneksel çiftçiler tarafından gerçekleştirilen seleksiyonun etkisiyle zaman içerisinde şekillenmiştir. Bu nedenle yerel çeşitler; soğuğa, yüksek sıcaklıklara ve kuraklığa tolerans; başaklanma ve olgunlaşma zamanı ile tane dolum süresi; bitki patojenlerinin neden olduğu hastalıklara dayanıklılık ve diğer olumsuz çevresel stres faktörlerine tolerans gibi arzu edilen özellikler bakımından önemli bir genetik çeşitlilik kaynağı niteliğindedir (Jaradat, 2011).

Anadolu yerel buğdaylarının önemli bir özelliği, çok farklı yetiştirme çevrelerinde uzun süre üretimde kalmış olmalarıdır. Türkiye'de buğday yetiştiriciliği; kıyı bölgelerinden yüksek rakımlı Doğu Anadolu'ya, yüksek yağışlı geçiş bölgelerinden kurak Orta ve Güneydoğu Anadolu koşullarına kadar oldukça geniş bir ekolojik aralıkta gerçekleştirilmektedir. Bu ekolojik farklılaşma; bitki boyu, başak özellikleri, çiçeklenme zamanı, tane büyüklüğü, kışa dayanıklılık, tane kalitesi ve diğer adaptif özellikler bakımından geniş varyasyon oluşmasına neden olmuştur (Zencirci & Karagöz, 2005; Alsaleh et al., 2016). Bitkilerdeki tüm bileşiklerin içeriği, genotip ve çevrenin yanı sıra bunların etkileşimlerinden de etkilenmektedir. Bununla birlikte, bu farklı parametreler üzerindeki etki düzeyi, bitki materyalinin seçimine, yetiştirme ortamına ve yetiştirme uygulamalarına bağlıdır (Johansson ve ark. 2014).

Türkiye genelinde gerçekleştirilen geniş ölçekli örnekleme çalışmalarında 59 ilden 1600'den fazla çiftçinin tarlalarından yerel buğday materyalleri toplanmış ve siyez, gernik, topbaş, makarnalık ve ekmeklik buğdayları kapsayan 95 farklı morfotip tanımlanmıştır. Bununla birlikte günümüzde belirlenen çeşitliliğin yaklaşık bir asır önce kaydedilmiş buğday çeşitliliğiyle karşılaştırılması, bazı bölgelerde önemli düzeyde genetik erozyon meydana geldiğini göstermektedir (Morgounov et al., 2016).

Yerel çeşitler, yoğun girdili üretim sistemlerine uyumlu Yeşil Devrim'in yarı bodur modern çeşitlerinin yaygınlaşmasıyla bitkisel üretimdeki yerlerini büyük ölçüde kaybetmiştir (Royo ve ark., 2009). Bununla birlikte yerel çeşitler, yoğun girdili üretim sistemlerine uyumlu Yeşil Devrim'in yarı bodur modern çeşitlerinin yaygınlaşmasıyla bitkisel üretimdeki yerlerini büyük ölçüde kaybetmiştir (Lopez ve ark.,

2015). Bu durum yerel çeşitlerin yalnızca kültürel miras olarak değil, geleceğin sürdürülebilir buğday üretim sistemleri için önemli genetik kaynaklar olarak değerlendirilmesini zorunlu kılmaktadır.

DÜŞÜK GİRDİLİ TARIM SİSTEMLERİNDE ANADOLU YEREL BUĞDAYLARININ POTANSİYELİ

Düşük girdili tarım sistemleri, sentetik gübre, pestisit, sulama suyu, enerji ve diğer dış girdilerin kullanımının sınırlandırıldığı veya daha etkin hâle getirildiği üretim yaklaşımlarını kapsamaktadır. Bu sistemlerde yalnızca birim alandan maksimum verim elde etmek değil, kullanılan kaynak başına üretimin artırılması ve çevresel sürdürülebilirliğin sağlanması amaçlanmaktadır. Bu nedenle düşük girdili koşullara uygun çeşitlerden beklenen özellikler de yüksek girdili sistemler için geliştirilen çeşitlerden kısmen farklılaşmaktadır. Kök sisteminin gelişmiş olması, su ve besin elementlerinden etkin yararlanma, yabancı otlarla rekabet, hastalık dayanıklılığı, çevresel değişkenliğe tolerans ve kabul edilebilir düzeyde verim kararlılığı bu özelliklerin başında gelmektedir (Ceccarelli, 1996; Wolfe et al., 2008; Lammerts van Bueren et al., 2011).

Kuraklık, Türkiye'de özellikle Orta Anadolu ve Güneydoğu Anadolu'da buğday üretimini sınırlandıran en önemli abiyotik streslerden biridir. Yerel buğdayların uzun süre yağışa dayalı koşullarda yetiştirilmesi; fenolojik plastisite, farklı kök mimarileri, erken gelişme, biyokütle dağılımı ve su kullanım stratejileri gibi özelliklerde geniş bir varyasyon oluşmasına katkı sağlamıştır. Türkiye kökenli yerel makarnalık ve ekmeklik buğdaylarda çevresel stres toleransı ve adaptif özellikler bakımından önemli farklılıkların bulunması, bu materyallerin kuraklık ıslahında kullanılabilecek gen kaynakları olduğunu göstermektedir (Damania et al., 1996, 1997; Morgounov et al., 2016; Kaya, 2021; Demirdogen ve ark., 2024).

Düşük girdili üretimin bir diğer önemli bileşeni azotlu gübre kullanımının azaltılmasıdır. Azotlu gübrelerin üretimi için gereken enerji maliyeti oldukça yüksek olup (Smil, 2001), azotlu gübreleme tahıl temelli üretim sistemlerinde çoğu zaman en yüksek enerji girdilerinden birini oluşturmaktadır (Crews & Peoples, 2004). Yerel buğdaylar arasında kök gelişimi, biyokütle üretimi, tane protein oranı ve besin elementi alımı bakımından geniş varyasyon bulunmasına rağmen, modern çeşitlerin bazı koşullarda azot kullanım etkinliği bakımından daha başarılı olabileceği de bilinmektedir. Bu nedenle yerel çeşitlerin düşük azot koşullarındaki önemi, doğrudan genelleştirilebilecek bir üstünlükten çok, üstün genotiplerin ve faydalı allellerin belirlenebileceği geniş bir genetik havuz oluşturmalarından kaynaklanmaktadır (Fageria, 2008; Elbasyoni, 2019).

Yerel çeşitlerin birçok modern yarı bodur çeşide kıyasla daha uzun bitki yapısına sahip olması da düşük girdili üretimde hem avantaj hem dezavantaj oluşturabilmektedir. Uzun bitki boyu, yüksek biyokütle ve hızlı toprak kapatma özelliği özellikle herbisit kullanımının sınırlandırıldığı sistemlerde yabancı otlarla rekabeti artırabilir. Buna karşılık yüksek bitki boyu, uygun nem ve besin koşullarında yatma riskini yükseltebilir. Bu nedenle düşük girdili sistemlere uygun yeni çeşitlerin geliştirilmesinde yerel materyalin yabancı ot rekabeti gibi olumlu özellikleri ile modern çeşitlerin yatmaya dayanıklılık özelliklerinin birleştirilmesi önemli olabilir (Wolfe ve ark., 2008; Bertholdsson ve ark., 2016).

Yerel buğdayların dikkat çekici yönlerinden biri de tane ve ürün kalitesidir. Anadolu'da uzun yıllardır yetiştirilen yerel buğdayların önemli bir bölümü geleneksel ekmek, bulgur, erişte ve diğer yöresel ürünlerin üretiminde kullanılmaktadır. Yerel materyaller arasında tane iriliği, camsılık, protein oranı, gluten özellikleri, pigment içeriği ve diğer kalite parametreleri bakımından geniş varyasyon bulunmaktadır. Özellikle Anadolu'nun geleneksel makarnalık buğdaylarından Kunduru materyalinde yüksek düzeyde fenotipik ve kalite çeşitliliği belirlenmiştir. Bu özellikler, yerel buğdayların düşük girdili sistemlerde yalnızca verim odaklı değil, yüksek katma değerli ürünlerin hammaddesi olarak da değerlendirilmesine olanak sağlamaktadır (Akçura, 2009; Alsaleh ve ark., 2016; Zencirci, 2008).

YEREL BUĞDAY GENETİK KAYNAKLARININ KORUNMASI VE ISLAH POTANSİYELİ

Anadolu yerel buğdayları, uzun yıllar boyunca farklı ekolojik koşullar ve çiftçi seleksiyonu altında şekillenmiş geniş bir genetik çeşitliliğe sahip önemli bitki genetik kaynaklarıdır (Karagöz, 2014). Türkiye'de bu çeşitliliğin korunmasına yönelik toplama ve kayıt altına alma çalışmaları uzun bir geçmişe sahip olup, farklı dönemlerde gerçekleştirilen araştırmalar yerel buğday genetik kaynaklarının belirlenmesi ve ex situ koşullarda muhafaza edilmesine önemli katkılar sağlamıştır (Harlan, 1950; Damania ve ark., 1996; Karagöz, 1996; Qualset ve ark., 1997; Tan, 2002; Karagöz ve Zencirci, 2005; Akçura ve Topal, 2006; Giuliani ve ark., 2009). Bu çalışmalar sonucunda Anadolu'nun geçmişte sahip

olduğu yerel buğday çeşitliliğinin önemli bir bölümü, Türkiye'de ve farklı ülkelerde bulunan gen bankası koleksiyonlarında korunmaktadır. Bununla birlikte, gen bankalarında gerçekleştirilen ex situ korumanın yanı sıra, yerel çeşitlerin yetiştirildikleri alanlarda korunması genetik çeşitliliğin devamlılığı açısından önem taşımaktadır. Yerel çeşitlerin güncel durumunun ve yetiştirildikleri bölgelerin belirlenmesine yönelik envanter çalışmalarının, in situ/on-farm koruma stratejilerinin geliştirilmesi ve bu genetik kaynakların sürdürülebilir kullanımının sağlanması açısından gerekli olduğu bildirilmektedir (Negri ve ark., 2012). Bu nedenle Anadolu yerel buğdaylarının hem gen bankalarında hem de çiftçi koşullarında korunması, sahip oldukları genetik çeşitliliğin gelecek nesillere aktarılması ve gelecekteki buğday ıslah çalışmalarında kullanılabilmesi açısından önem taşımaktadır.

Yerel buğdayların korunmasının yanı sıra agronomik, fizyolojik, kalite ve adaptasyon özellikleri bakımından karakterize edilmesi de büyük önem taşımaktadır. Anadolu yerel buğdaylarında farklı yükselti ve yetiştirme bölgelerine bağlı olarak önemli fenotipik farklılıkların bulunması, bu materyallerin farklı çevre koşullarına adaptasyon bakımından geniş bir varyasyon taşıdığını göstermektedir (Karagöz ve Zencirci, 2005; Damania ve ark., 1996). Bu çeşitlilik, özellikle düşük girdili ve çevresel streslerin belirgin olduğu üretim sistemleri açısından değerli genotiplerin belirlenmesine olanak sağlamaktadır.

Moleküler markör ve genomik teknolojilerdeki gelişmeler, yerel buğdaylarda bulunan genetik çeşitliliğin daha ayrıntılı olarak ortaya çıkarılmasına olanak sağlamıştır. DArTseq, SNP ve diğer yüksek çözünürlüklü moleküler yaklaşımlarla gerçekleştirilen çalışmalar, Anadolu ve yakın çevresindeki buğday materyallerinde geniş genomik varyasyon bulunduğunu ve bu varyasyonun ıslah çalışmalarında değerlendirilebileceğini göstermektedir (Sehgal ve ark., 2016; Baloch ve ark., 2017; Alsaleh ve ark., 2022).

Bu nedenle Anadolu yerel buğdaylarının korunması, yalnızca mevcut genetik çeşitliliğin muhafaza edilmesiyle sınırlı kalmamalı, bu materyallerin modern buğday ıslahına entegrasyonu da hedeflenmelidir. Özellikle kuraklık toleransı, azot kullanım etkinliği, hastalık direnci, yabancı otlarla rekabet, tane kalitesi ve verim kararlılığı bakımından üstün genotiplerin belirlenmesi, düşük girdili koşullara uygun yeni çeşitlerin geliştirilmesine katkı sağlayabilir. Böylece yerel materyallerin adaptif özellikleri ile modern çeşitlerin yüksek verim ve agronomik uygunluk özelliklerinin bir araya getirilmesi mümkün olabilir (Ceccarelli, 1996; Wolfe et al., 2008; Sehgal et al., 2016).

SONUÇ

Anadolu yerel buğdayları, uzun süreli doğal ve çiftçi seleksiyonu sonucunda farklı yetiştirme çevrelerine uyum sağlamış ve geniş genetik çeşitlilik kazanmış önemli bitkisel genetik kaynaklardır. Anadolu'nun iklim, yükselti ve toprak özellikleri bakımından gösterdiği çeşitlilik, yerel buğday popülasyonlarında fenoloji, bitki morfolojisi, stres toleransı ve kalite özellikleri bakımından önemli varyasyonların ortaya çıkmasına katkıda bulunmuştur (Karagöz & Zencirci, 2005; Karagöz, 2014).

Düşük girdili tarım sistemlerinde çeşitlerden beklenen özellikler, yalnızca yüksek tane verimi ile sınırlı değildir. Su ve besin elementlerinden etkin yararlanma, biyotik ve abiyotik streslere tolerans, yabancı otlarla rekabet ve değişken çevre koşullarında verim kararlılığı da önem taşımaktadır. Yerel buğdayların sahip olduğu genetik çeşitlilik, bu özellikler bakımından uygun genotiplerin belirlenmesi açısından önemli bir kaynak oluşturmaktadır (Ceccarelli, 1996; Wolfe et al., 2008).

Anadolu yerel buğdaylarının düşük girdili tarım açısından temel değeri, modern çeşitlere doğrudan alternatif oluşturmalarından çok, gelecekteki ıslah çalışmalarında kullanılabilecek genetik çeşitliliği barındırmalarından kaynaklanmaktadır. Yerel materyallerde bulunan adaptif özelliklerin modern çeşitlerin yüksek verim ve agronomik özellikleriyle birleştirilmesi, daha az dış girdiye ihtiyaç duyan ve çevresel değişkenliğe daha iyi uyum sağlayabilen yeni çeşitlerin geliştirilmesine katkı sağlayabilir (Ceccarelli, 1994, 1996; Sehgal et al., 2016).

Sonuç olarak Anadolu yerel buğdaylarının korunması, karakterize edilmesi ve ıslah programlarında etkin biçimde değerlendirilmesi, düşük girdili buğday üretiminin sürdürülebilirliği açısından önem taşımaktadır. Genetik kaynakların ex situ ve on-farm yöntemlerle korunması ile agronomik, fizyolojik ve genomik karakterizasyon çalışmalarının birlikte yürütülmesi, bu materyallerde bulunan faydalı genetik varyasyonun geleceğin buğday çeşitlerine aktarılmasına olanak sağlayacaktır (Morgounov et al., 2016; Baloch et al., 2017; Alsaleh et al., 2022).

ÖZET

Bu araştırmanın amacı, *Sitophilus oryzae* L. (pirinç biti) ile buğday ilişkili literatürün bilimsel üretim yapısını, gelişim eğilimlerini, atıf örüntülerini, kavramsal temalarını ve iş birliği ağlarını bibliyometrik yöntemlerle incelemektir. Veriler, Web of Science Core Collection veri tabanında 5 Temmuz 2026 tarihinde gerçekleştirilen taramadan elde edilmiştir. *Sitophilus oryzae* ya da rice weevil terimleri ile buğdayı karşılayan terimlerin birlikte kullanıldığı sorguda başlangıçta 854 yayına ulaşılmış; yalnızca İngilizce makalelerin seçilmesiyle 1946-2026 dönemini kapsayan 796 çalışma analize alınmıştır. Veriler R programlama diliyle çözümlenmiş; yıllık yayın üretimi, yaşam döngüsü, üretken yazar, ülke, kurum ve dergiler, atıf yapısı, yazar anahtar kelimeleri, tematik eğilimler ve ortak yazarlık ağları incelenmiştir. Bulgular, 2000'li yıllardan sonra artan yayın üretiminin özellikle 2015 sonrasında hızlandığını ve 2021'de 41 yayınla en yüksek düzeye ulaştığını göstermiştir. Lojistik yaşam döngüsü modeli, alanın henüz doygunluğa ulaşmadığına ve büyüme evresini sürdürdüğüne işaret etmiştir. Athanassiou CG, Kavallieratos NG ve Arthur FH en üretken yazarlar; Yunanistan ve ABD ise en görünür ülkeler olmuştur. Journal of Stored Products Research, hem yayın üretimi hem de yüksek atıflı çalışmalar bakımından alanın başlıca yayın platformu olarak belirlenmiştir. En üretken kurumlar University of Thessaly, Agricultural University of Athens ve Benaki Phytopathological Institute olarak saptanmıştır. Atıf analizi, bitkisel yağlar, fosfin direnci, diyatom toprağı ve depolama koşullarının etkili araştırma eksenleri olduğunu göstermiştir. Bulgular yalnızca Web of Science kapsamındaki İngilizce makaleleri yansıttığından bu sınırlılık gözetilerek dikkatle yorumlanmalıdır. Kavramsal yapı; *S. oryzae*, buğday, *Tribolium* türleri, *Rhyzopertha dominica* ve diyatom toprağı çevresinde şekillenmiştir. Son yıllarda direnç, toksisite, sıcaklık, spinosad ve alternatif mücadele yöntemleri daha görünür hâle gelmiştir. Türkiye 45 kayıtla ilk 20 ülke arasında yer almasına karşın uluslararası iş birliği ağında çevresel bir konumda kalmıştır. Sonuçlar, literatürün entomoloji merkezli olmakla birlikte tarım, gıda bilimi, bitki bilimleri ve sürdürülebilir zararlı yönetimiyle ilişkili disiplinler arası bir yapıda geliştiğini göstermektedir. Türkiye merkezli araştırmaların uluslararası ortaklıkları artırması ve çevre dostu kontrol yaklaşımlarına yönelmesi önerilmektedir.

Anahtar kelimeler: *S. oryzae*, pirinç biti, buğday, depo zararlıları, bibliyometrik analiz, zararlı yönetimi

ABSTRACT

This study examined the scientific output, publication trends, citation patterns, conceptual themes, and collaboration networks of research on *Sitophilus oryzae* L. (rice weevil) and wheat using bibliometric methods. Data were retrieved from the Web of Science Core Collection through a search conducted on 5 July 2026. The search combined the terms *S. oryzae* or rice weevil with terms referring to wheat. It initially yielded 854 records; after limiting the results to English-language articles, 796 publications covering the period 1946-2026 were included. Data were analyzed in R to assess annual scientific production, publication life cycle, prolific authors, countries, institutions, and journals, citation structure, author keywords, thematic trends, and co-authorship networks. Results showed that publication output increased after 2000, accelerated after 2015, and peaked at 41 articles in 2021. The logistic life-cycle model indicated that the field has not yet reached saturation and remains in a growth phase. Athanassiou CG, Kavallieratos NG, and Arthur FH were the most prolific authors, while Greece

and the United States were the most prominent countries. Journal of Stored Products Research emerged as the leading outlet in both publication output and highly cited studies. The University of Thessaly, Agricultural University of Athens, and Benaki Phytopathological Institute were the most productive institutions. Citation analysis identified botanical oils, phosphine resistance, diatomaceous earth, and storage conditions as influential research areas. The conceptual structure centered on *S. oryzae*, wheat, *Tribolium* species, *Rhyzopertha dominica*, and diatomaceous earth, whereas resistance, toxicity, temperature, spinosad, and alternative control methods gained visibility in recent years. Türkiye ranked among the top 20 countries with 45 records but occupied a peripheral position in the international collaboration network. Overall, the literature remains entomology-centered while displaying interdisciplinary links with agriculture, food science, plant sciences, and sustainable pest management. Strengthening international collaboration and environmentally friendly control research is recommended, particularly for Türkiye.
Keywords: *S. oryzae*, rice weevil, wheat, stored-product pests, bibliometric analysis, pest management.

GİRİŞ

Depolanmış tahılların korunması, yalnızca tarımsal üretimin devamı açısından değil, gıda güvenliği, ürün kalitesi ve ekonomik kayıpların azaltılması bakımından da stratejik bir konudur. Gıda güvenliği; bireylerin her zaman yeterli, güvenli ve besleyici gıdaya fiziksel ve ekonomik olarak erişebilmesiyle ilişkilendirilmektedir (FAO, 2008). Bu nedenle gıdanın üretimden tüketime kadar geçen süreçte korunması, özellikle buğday gibi temel tahıllarda, gıda arzının sürekliliği açısından kritik önem taşımaktadır. Hasat sonrası dönemde ortaya çıkan zararlı kaynaklı kayıplar, ürün miktarında azalmaya, kalite bozulmasına, ticari değer kaybına ve tüketici sağlığı açısından risklerin artmasına neden olabilmektedir.

Depolanmış ürün zararlıları içinde *S. oryzae* L. (Coleoptera: Curculionidae), yaygınlığı ve zarar potansiyeli nedeniyle öne çıkan türlerden biridir. Literatürde pirinç biti olarak adlandırılmasına karşın bu zararlı yalnızca pirinçle sınırlı değildir; buğday, arpa, mısır ve sorgum gibi farklı tahıl ürünlerinde de zarar oluşturabilmektedir (Kandel et al., 2021). Pirinç bitinin önemli bir depolanmış tahıl zararlısı olarak değerlendirilmesinde, ergin ve larva dönemlerinin ürüne doğrudan zarar vermesi belirleyicidir. Özellikle larvaların dane içinde gelişmesi, zararın dışarıdan kolaylıkla fark edilmesini güçleştirmekte ve bulaşık danelerin ayıklanmasını zorlaştırmaktadır. Bu yönüyle *S. oryzae*, depolanmış buğdayda hem nicel hem de nitel kayıplara yol açan başlıca zararlılar arasında kabul edilmektedir (Flinn et al., 2007; Hagstrum et al., 2012).

Buğdayın depolanması sırasında zararlıların gelişimi; sıcaklık, nem (ortam ve tane), depolama süresi, hijyen koşulları ve mücadele yöntemleri gibi çok sayıda faktörden etkilenmektedir. Depo ortamındaki sıcaklık ve nem değişimleri, böcek popülasyonlarının çoğalma hızını ve zararın şiddetini belirleyebilmektedir. Bu nedenle depolanmış ürün zararlılarıyla mücadelede yalnızca kimyasal uygulamalara dayalı bir yaklaşım yeterli görülmemekte; izleme, erken tespit, hijyen, sıcaklık-nem yönetimi ve entegre zararlı yönetimi uygulamalarının birlikte ele alınması önerilmektedir (Hagstrum et al., 2012). Bununla birlikte fosfin başta olmak üzere fumigantların uzun yıllardır yoğun biçimde kullanılması, direnç gelişimi, kalıntı riski ve çevresel etkiler gibi sorunları gündeme getirmiştir (Yılmaz Doğu & Emekci, 2026). Bu durum, *S. oryzae* ile mücadelede alternatif ve çevre dostu yöntemlere yönelik araştırmaların artmasına zemin hazırlamıştır.

Son yıllarda diyatom toprağı, bitkisel yağlar, uçucu yağlar, sıcaklık uygulamaları, kontrollü atmosfer, hipoksi, spinosad ve diğer düşük riskli mücadele yaklaşımları, depolanmış ürün zararlıları literatüründe daha görünür hâle gelmiştir. Diyatom toprağına ilişkin çalışmalar, bu materyalin böcek kutikulasındaki mumsu tabakayı aşındırarak dehidrasyona yol açması nedeniyle fiziksel etki mekanizmasına sahip doğal bir insektisit olarak değerlendirildiğini göstermektedir (Korunić, 1998). Pirinç bitine karşı buğday ve arpada yürütülen çalışmalar, diyatom toprağının etkinliğinin uygulama dozu, sıcaklık, nem, tane nemi ve zararlı türüne göre değişebildiğini ortaya koymuştur (Athanassiou et al., 2005; Yılmaz Doğu & Emekci, 2026). Benzer biçimde bitkisel kökenli bileşikler ve uçucu yağlar da depolanmış ürün zararlılarına karşı alternatif mücadele olanakları kapsamında ele alınmaktadır (Kim et al., 2003; Shaaya et al., 1997). Bu araştırma yönelimleri, alanın yalnızca klasik kimyasal mücadele ekseninde değil, sürdürülebilir zararlı yönetimi çerçevesinde de geliştiğini göstermektedir.

Pirinç biti ve buğday ilişkili literatür, entomoloji merkezli olmakla birlikte tarım, gıda bilimi, bitki koruma, depolama teknolojileri ve sürdürülebilir üretim gibi farklı disiplinlerle kesişen bir yapıya

sahiptir. Bu çok disiplinli yapı, alandaki bilimsel üretimin yalnızca yayın sayıları üzerinden değil; etkili yazarlar, ülkeler, kurumlar, dergiler, atıf örüntüleri, anahtar kelimeler ve iş birliği ağları üzerinden de incelenmesini gerekli kılmaktadır. Çünkü belirli bir araştırma alanının gelişim çizgisi, hangi konuların merkezde yer aldığı, hangi temaların yükselişe geçtiği ve hangi ülkelerin ya da kurumların bilgi üretiminde belirleyici olduğu ancak bütüncül bir bilim haritalama yaklaşımıyla anlaşılabilir.

Bibliyometrik analiz, büyük ölçekli akademik literatürü nicel göstergeler aracılığıyla incelemeye olanak tanıyan güçlü bir yöntemdir. Bu yaklaşım; yayın üretimi, atıf ilişkileri, ortak yazarlık ağları, ülke ve kurum iş birlikleri, kavramsal yapı ve tematik eğilimlerin sistematik biçimde değerlendirilmesine imkân sağlar (Zupic & Čater, 2015). Özellikle bilim haritalama teknikleri, araştırma alanlarının zaman içinde nasıl geliştiğini, hangi kavramların merkezî konuma geldiğini ve hangi konuların yeni eğilimler olarak ortaya çıktığını görünür kılar. R tabanlı bibliometrix paketi gibi araçlar, bibliyometrik verilerin düzenlenmesi, çözümlenmesi ve görselleştirilmesi için kapsamlı bir iş akışı sunmaktadır (Aria & Cuccurullo, 2017). Bu yönüyle bibliyometrik analiz, pirinç biti ve buğday ilişkili literatürün uzun dönemli gelişimini değerlendirmek için uygun bir yöntemsel çerçeve sağlamaktadır.

Bu alanda pirinç bitinin biyolojisi, depolanmış tahıllardaki zararı, fumigantlara duyarlılığı, direnç gelişimi ve alternatif mücadele yöntemleri üzerine çok sayıda deneysel çalışma bulunmaktadır. Ancak bu çalışmaların önemli bir kısmı belirli bir mücadele yöntemi, belirli bir zararlı türü, belirli bir ürün ya da belirli bir çevresel koşul üzerine odaklanmaktadır. Buna karşılık pirinç biti ve buğday eksenindeki bilimsel üretimin tarihsel gelişimini, etkili yayınları, üretken araştırmacıları, kurumsal ve ülkesel katkıları, kavramsal temaları ve iş birliği ağlarını birlikte değerlendiren bibliyometrik çalışmalar sınırlıdır. Bu eksiklik, alanın genel yapısının, araştırma boşluklarının ve gelecekte güçlenebilecek tematik yönelimlerin belirlenmesini zorlaştırmaktadır.

Bu araştırmanın amacı, pirinç biti ve buğday ilişkili çalışmaların bilimsel üretim yapısını, kavramsal gelişimini, atıf örüntülerini ve iş birliği ağlarını bibliyometrik analiz yoluyla incelemektir. Bu amaç doğrultusunda aşağıdaki araştırma sorularına yanıt aranmıştır:

1. Pirinç bitive buğday ilişkili çalışmaların yıllara göre yayın üretim eğilimi nasıldır?
2. Bu alanda en üretken yazarlar, ülkeler/bölgeler, kurumlar ve kaynaklar/dergiler hangileridir?
3. Alandaki en çok atıf alan yayınlar ve etkili çalışmalar hangi konular etrafında yoğunlaşmaktadır?
4. Yazar anahtar kelimelerine göre alanın kavramsal yapısı, temel temaları ve trend konuları nelerdir?
5. Ülke ve yazar iş birliği ağları, alandaki bilimsel iş birliği örüntüleri hakkında ne göstermektedir?

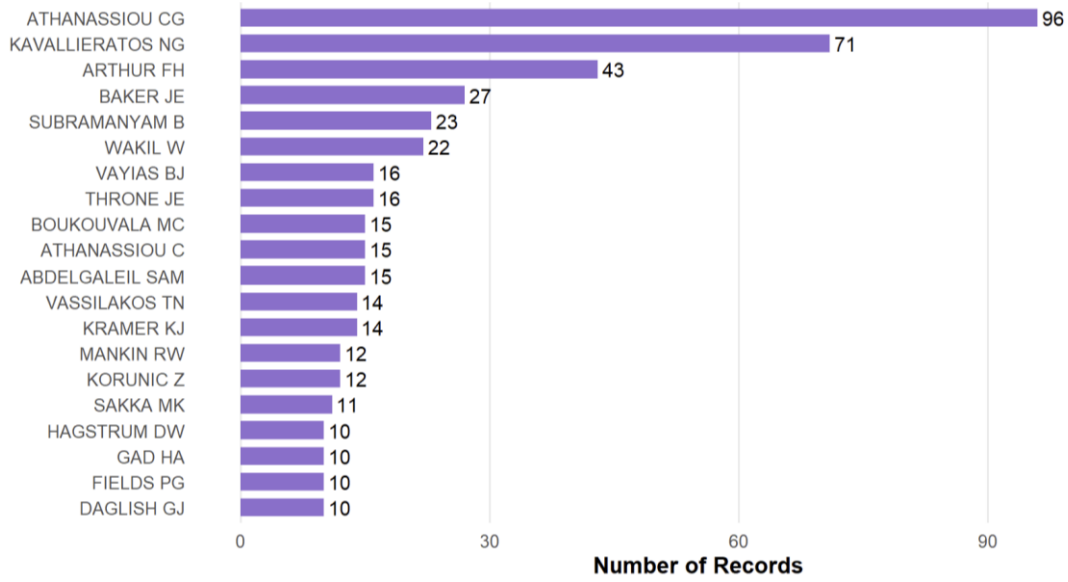
YÖNTEM

Bu araştırma, pirinç biti ve buğday ilişkili bilimsel yayınların gelişimini, kavramsal yapısını, atıf örüntülerini ve iş birliği ağlarını incelemek amacıyla bibliyometrik araştırma deseniyle tasarlanmıştır (Donthu et al., 2021; Zupic & Čater, 2015). Bibliyometrik analiz, belirli bir araştırma alanında üretilen bilimsel yayınların yıllara göre dağılımını, üretken yazar, ülke, kurum ve kaynaklarını, atıf yapılarını, anahtar kelime örüntülerini ve bilimsel iş birliği ağlarını nicel göstergeler aracılığıyla incelemeye olanak sağlayan bir yöntemdir. Bu doğrultuda araştırmada tanımlayıcı bibliyometrik göstergeler, ağ analizleri ve tematik analizler birlikte kullanılmıştır.

Veri Kaynağı ve Arama Stratejisi

Araştırmanın veri kaynağını Web of Science Core Collection veri tabanında indekslenen yayınlar oluşturmuştur. Veri tabanı taraması 5 Temmuz 2026 tarihinde saat 23.30'da gerçekleştirilmiştir. Tarama sürecinde pirinç biti ile buğdayı karşılayan terimler birlikte kullanılmıştır. Araştırmanın tekrarlanabilirliğini sağlamak amacıyla kullanılan arama sorgusu aşağıda verilmiştir:

TS = ((“*Sitophilus oryzae*” OR “rice weevil”) AND (“*Triticum aestivum*” OR wheat OR “common wheat”))



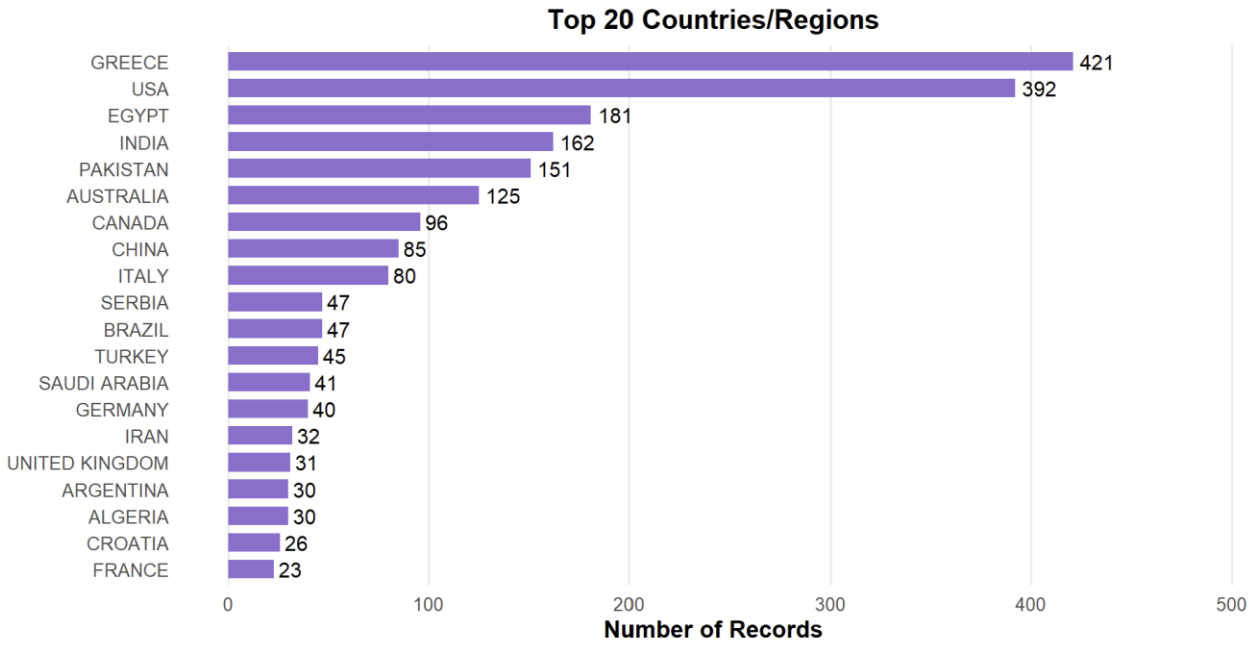
İlk tarama sonucunda 854 yayına ulaşılmıştır. Daha sonra araştırmanın kapsamı doğrultusunda dahil etme ve dışlama ölçütleri uygulanmıştır. Dahil etme ölçütleri; yayının Web of Science Core Collection veri tabanında indekslenmiş olması, İngilizce yayımlanmış olması ve belge türünün makale olması şeklinde belirlenmiştir. Kitap bölümleri, bildiriler, derlemeler, editoryal materyaller, notlar, erken erişim dışındaki uygun olmayan kayıtlar ve İngilizce dışındaki yayınlar analiz kapsamı dışında bırakılmıştır. Böylece analizlerin yalnızca hakemli makaleler üzerinden yürütülmesi ve veri setinin daha homojen bir

yapıya sahip olması amaçlanmıştır. Bu ölçütlerin uygulanmasının ardından nihai veri seti 1946-2026 dönemini kapsayan 796 makaleden oluşmuştur.

Elde edilen bibliyografik veriler Web of Science veri tabanından uygun dosya formatında dışa aktarılmış ve R programlama dili kullanılarak analiz edilmiştir. Analiz sürecinde yıllık yayın üretimi, yayınların yaşam döngüsü, en üretken yazarlar, ülkeler, kurumlar ve kaynaklar/dergiler belirlenmiştir. Ayrıca en çok atıf alan yayınlar, yazar anahtar kelimeleri, tematik eğilimler ve kavramsal yapı incelenmiştir. Bilimsel iş birliği örüntülerini ortaya koymak amacıyla ülke ve yazar düzeyinde ortak yazarlık ağları analiz edilmiştir. Bu analizler aracılığıyla alanın tarihsel gelişimi, temel araştırma eksenleri, yükselen temaları ve uluslararası iş birliği yapısı bütüncül biçimde değerlendirilmiştir.

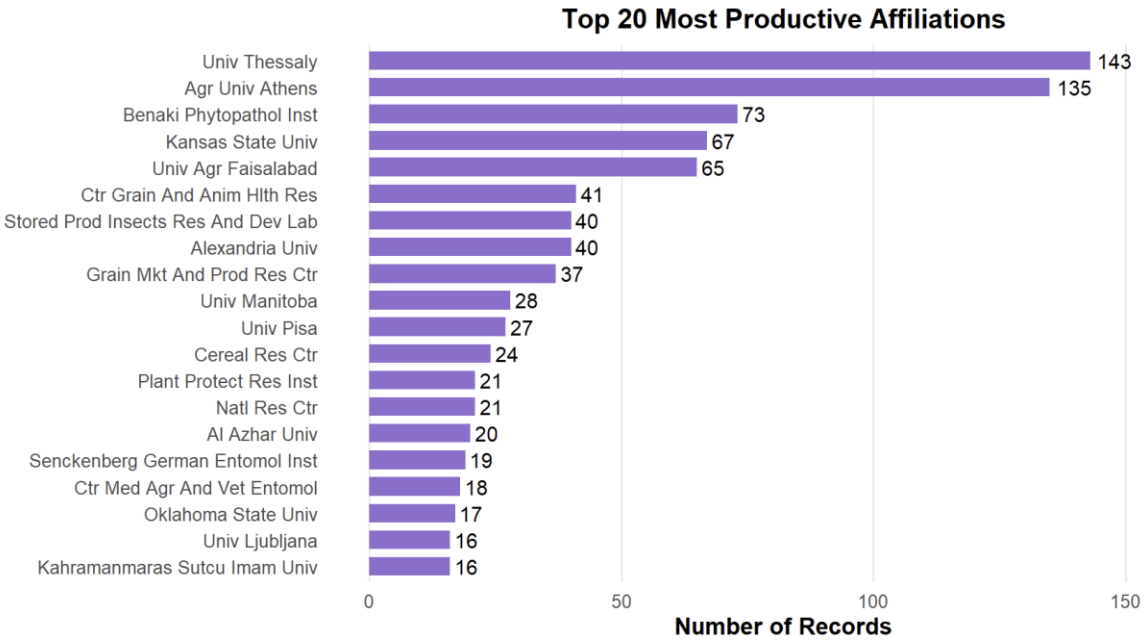
ARAŞTIRMA BULGULARI VE TARTIŞMA

Şekil 1, alandaki en üretken 20 yazarı göstermektedir. Athanassiou CG 96 kayıtla en üretken yazar olurken, onu 71 kayıtla Kavallieratos NG ve 43 kayıtla Arthur FH izlemiştir. Bu bulgu, literatürün görece sınırlı sayıda yüksek üretkenliğe sahip araştırmacılar tarafından şekillendirildiğini göstermektedir.



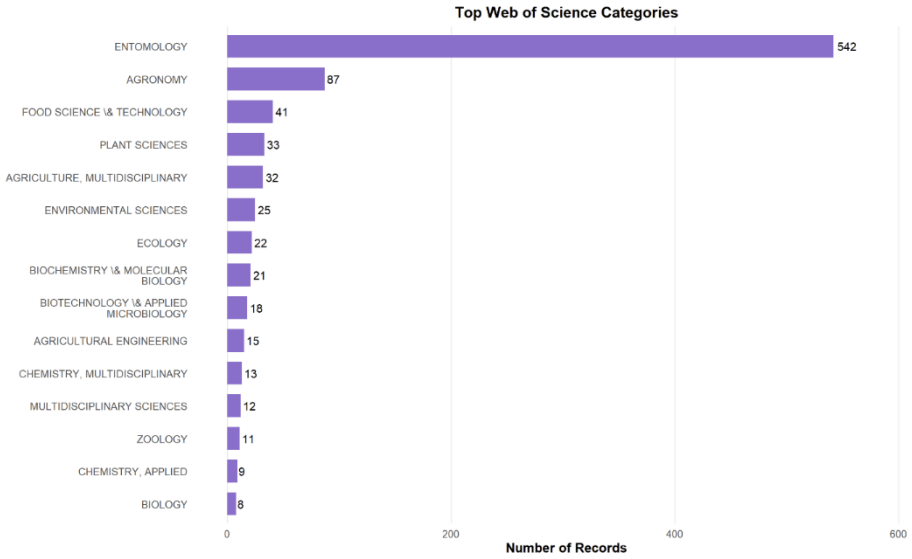
Şekil 1. Alandaki En Üretken 20 Yazar

Şekil 2'e göre Türkiye, yazar adreslerine dayalı ülke/bölge dağılımında 45 kayıt ile ilk 20 ülke arasında yer almaktadır. Türkiye bu sayı ile Yunanistan, ABD, Mısır, Hindistan, Pakistan, Avustralya, Kanada, Çin, İtalya, Sırbistan ve Brezilya'nın ardından gelmektedir. Bu bulgu, Türkiye'nin pirinç biti ve buğday ilişkili çalışmalar alanında görünür bir katkı sunduğunu, ancak alanın özellikle Yunanistan ve ABD merkezli daha yoğun bir üretim yapısına sahip olduğunu göstermektedir. Türkiye'de depolanmış buğday zararlıları ve diyatom toprağı gibi alternatif mücadele yöntemleri üzerine yürütülen çalışmaların bulunması, uluslararası iş birlikleri için uygun bir araştırma zemininin mevcut olduğunu göstermektedir (Yılmaz Doğu & Emekci, 2026).



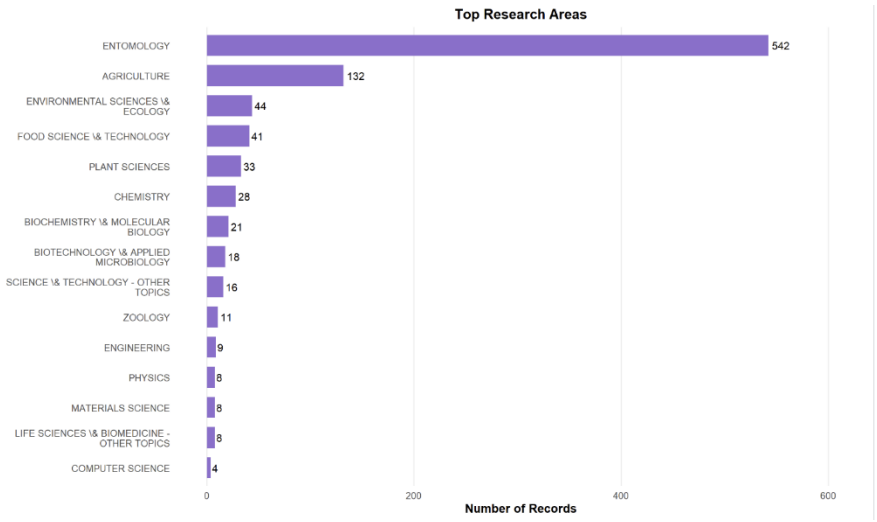
En üretken yazarlar ve kurumlara ilişkin bulgular, literatürün belirli araştırmacılar ve araştırma merkezleri etrafında yoğunlaştığını göstermektedir. Athanassiou CG, Kavallieratos NG ve Arthur FH'nin en üretken yazarlar olarak öne çıkması; University of Thessaly, Agricultural University of Athens ve Benaki Phytopathological Institute gibi Yunanistan merkezli kurumların üst sıralarda yer almasıyla birlikte değerlendirildiğinde, alanın özellikle Yunanistan merkezli güçlü bir araştırma hattına sahip olduğu anlaşılmaktadır (Şekil 1, 2). Bu durum ülke dağılımı bulgularıyla da tutarlıdır. Yunanistan ve ABD'nin hem yayın üretiminde hem de iş birliği ağlarında merkezi konumda bulunması, bu ülkelerin yalnızca nicel üretim bakımından değil, bilgi dolaşımı ve ortak araştırma yapıları bakımından da belirleyici aktörler olduğunu göstermektedir. Bibliyometrik çalışmalarda ortak yazarlık ve ülke iş birliği

ağları, araştırma alanındaki bilgi üretiminin sosyal ve kurumsal örgütlenmesini görünür kılan önemli göstergeler olarak değerlendirilmektedir (Zupic & Čater, 2015).



Şekil 2. Yazar Adreslerine Dayalı Ülke/Bölge Dağılımı

Yazar adreslerine göre en üretken kurumlar Şekil 3'te verilmiştir. Bulgulara göre University of Thessaly 143 kayıtla ilk sırada yer alırken, onu Agricultural University of Athens 135 kayıtla ve Benaki Phytopathological Institute 73 kayıtla izlemiştir. İlk üç kurumun Yunanistan merkezli olması, ülke dağılımında Yunanistan'ın ilk sırada yer almasıyla tutarlıdır. Ayrıca Kansas State University, University of Agriculture Faisalabad, Alexandria University ve University of Manitoba gibi kurumların da alana önemli katkı sunduğu görülmektedir. Türkiye'den Kahramanmaraş Sütçü İmam University 16 kayıtla ilk 20 kurum arasında yer almıştır.

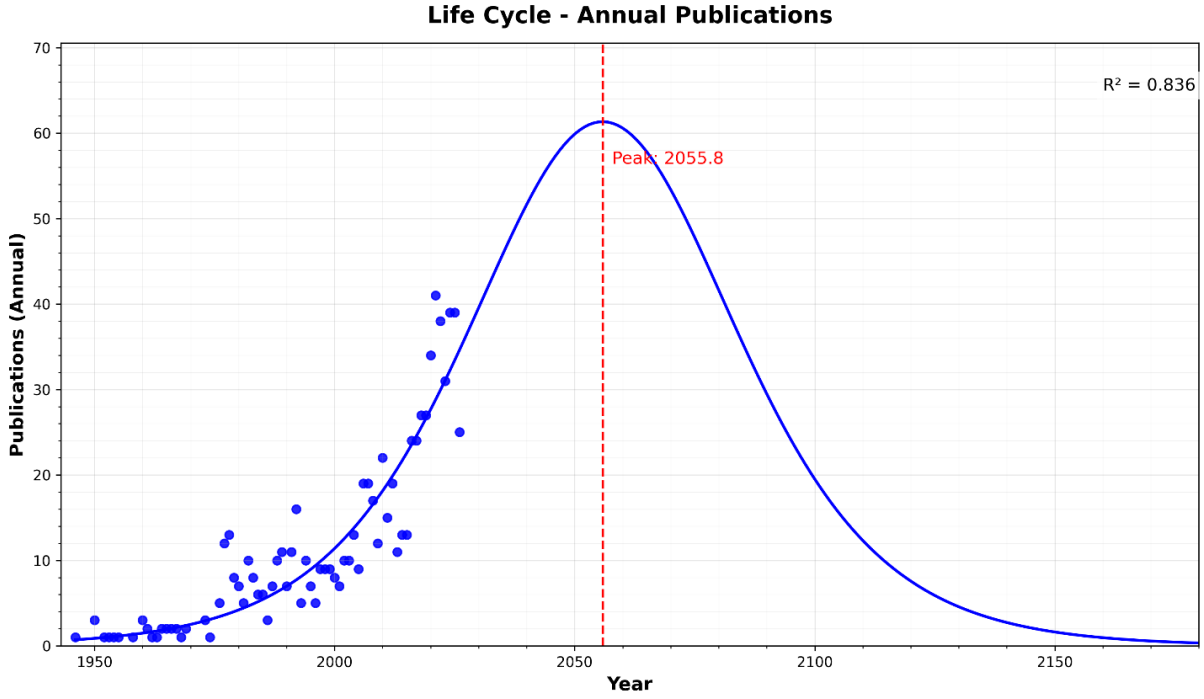


Şekil 3. Yazar Adreslerine Göre En Üretken Kurumlar

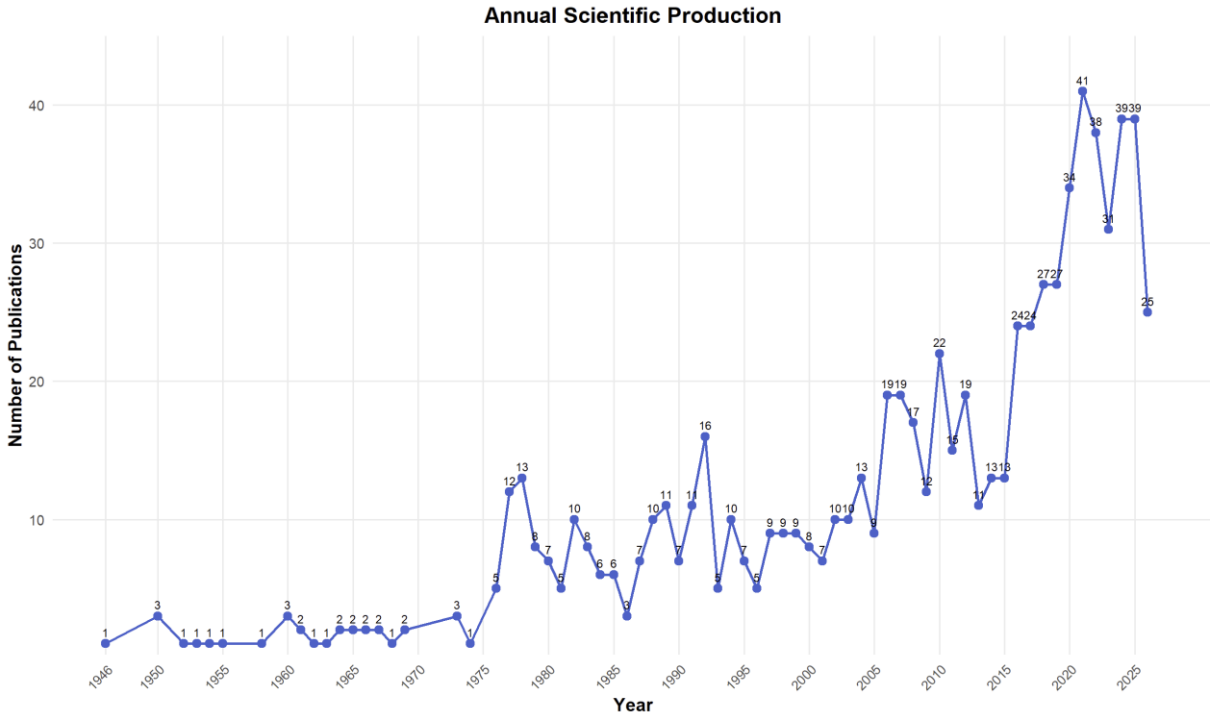
Yayınların Web of Science kategorilerine göre dağılımını ise Şekil 4'te gösterilmiştir. Entomology 542 kayıtla ilk sırada yer alırken, bunu 87 kayıtla Agronomy, 41 kayıtla Food Science & Technology, 33 kayıtla Plant Sciences ve 32 kayıtla Agriculture, Multidisciplinary kategorileri izlemiştir. Entomology kategorisinin açık biçimde ilk sırada yer alması beklenen bir sonuçtur; çünkü *S. oryzae* öncelikle depolanmış ürün entomolojisi kapsamında ele alınan bir zararlıdır. Bununla birlikte Agronomy, Food Science & Technology, Plant Sciences, Agriculture ve Environmental Sciences & Ecology alanlarının da görünür olması, konunun tek disiplinli bir çerçeveyle sınırlı olmadığını göstermektedir. Depolanmış buğdayda zararlı yönetimi; ürün kalitesi, gıda güvenliği, çevresel etki, kalıntı riski ve sürdürülebilir tarım uygulamalarıyla doğrudan ilişkilidir. Bu nedenle alanın entomoloji merkezli fakat tarım, gıda bilimi ve çevre bilimleriyle bağlantılı disiplinler arası bir yapı sergilemesi beklenen ve anlamlı bir bulgudur.

Şekil 4. Yayınların Web of Science Kategorilerine Göre Dağılımı

Şekil 5, yayınların araştırma alanlarına göre dağılımını göstermektedir. Bulgular, literatürün büyük ölçüde Entomoloji alanında yoğunlaştığını göstermektedir. Entomology 542 kayıtla ilk sırada yer alırken, bunu Agriculture 132 kayıtla, Environmental Sciences & Ecology 44 kayıtla, Food Science & Technology 41 kayıtla ve Plant Sciences 33 kayıtla izlemiştir. Bu dağılım, pirinç biti ve buğday ilişkili çalışmaların temel olarak entomoloji ve tarım bilimleri alanlarında konumlandığını; bununla birlikte çevre bilimleri, gıda bilimi ve bitki bilimleriyle de ilişkili olduğunu göstermektedir.



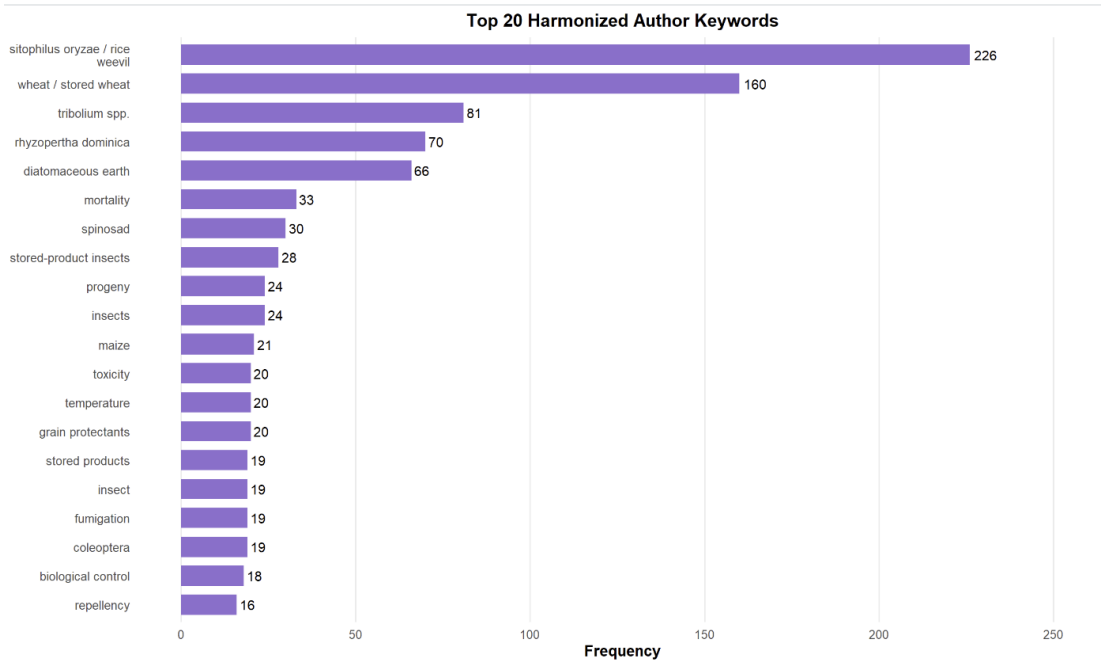
Şekil 5. Yayınların Araştırma Alanlarına Göre Dağılımı



1946 ile 2026 yılları arasındaki gözlemlenen yıllık yayın sayıları ve lojistik büyüme modelinin türevine dayalı tahmini yaşam döngüsü eğrisi Şekil 6'da verilmiştir. Modele göre yıllık yayın üretiminin tepe noktasına yaklaşık 2055.8 yılında ulaşacağı ve bu dönemde yıllık yayın sayısının yaklaşık 61.3 olacağı tahmin edilmektedir. Gözlenen yayınların eğrinin yükselen kısmında yoğunlaşması, alanın henüz yayın doygunluğuna ulaşmadığını ve hâlen büyüme evresinde olduğunu göstermektedir. Modelin uyum düzeyi ise $R^2 = 0.836$ olarak hesaplanmıştır.

Lojistik yaşam döngüsü analizinde yayın üretiminin tepe noktasına gelecekte ulaşacağının tahmin edilmesi, bu literatürün araştırma potansiyelinin devam ettiğini düşündürmektedir. Ancak bu bulgunun model temelli bir kestirim olduğu unutulmamalıdır. Bibliyometrik yaşam döngüsü analizleri, geçmiş yayın eğilimlerinden hareketle alanın gelişim yönünü değerlendirmeye imkân verse de gelecekteki yayın üretimi; iklim değişikliği, gıda güvenliği politikaları, depolama teknolojilerindeki gelişmeler, insektisit direnci ve alternatif mücadele yöntemlerine yönelik araştırma fonları gibi çok sayıda dış etkene bağlı olarak değişebilir. Bu nedenle model sonucunun kesin bir öngörüden çok, alanın mevcut büyüme eğilimini yansıtan analitik bir gösterge olarak yorumlanması daha uygundur.

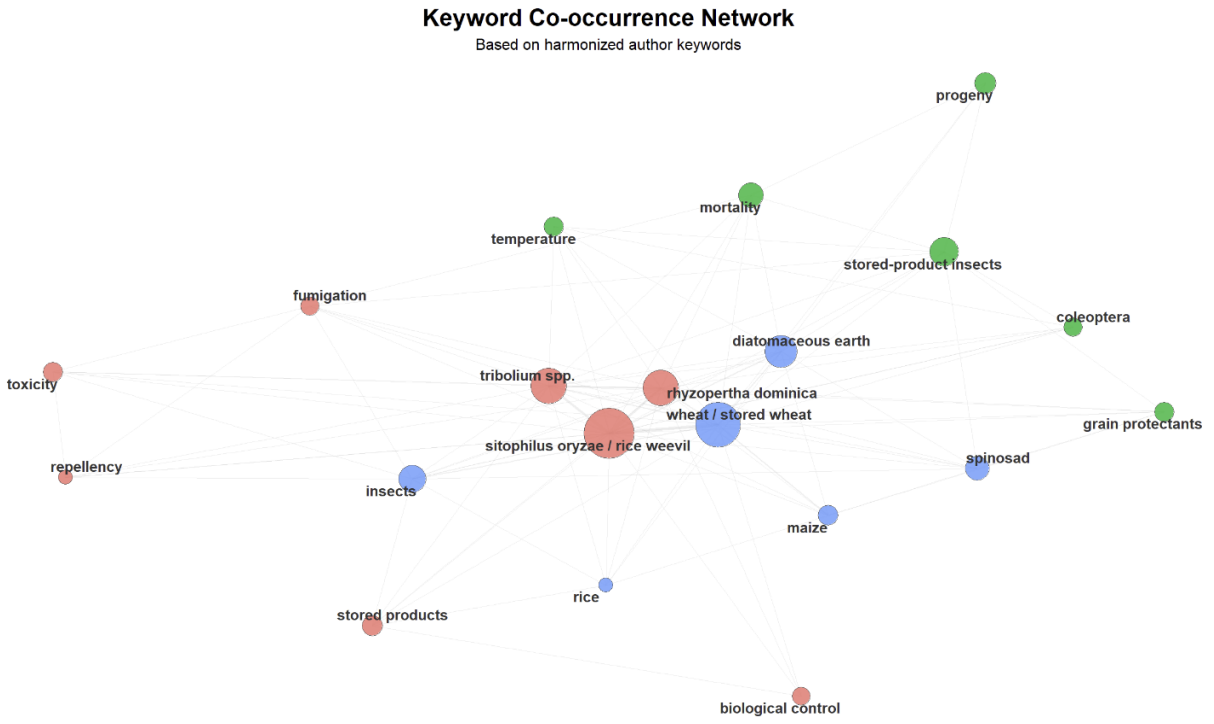
Şekil 7'de ise, 1946-2026 yılları arasında pirinç biti ve buğday ilişkili araştırmalara ait yıllık yayın sayılarını göstermektedir. Bulgular, 1946-1970'li yıllar arasında yayın üretiminin oldukça sınırlı kaldığını, 1970'lerin ikinci yarısından itibaren dalgalı bir artış başladığını göstermektedir. 2000'li yıllardan sonra yayın sayılarında daha belirgin bir yükseliş görülmüş, özellikle 2015 sonrası dönemde yayın üretimi hızlanmıştır. En yüksek yayın sayısına 2021 yılında 41 yayınla ulaşılmıştır. Yayın üretiminin özellikle 2015 sonrasında belirgin biçimde hızlanması, depolanmış tahıl zararlıları konusunun son dönemde daha fazla bilimsel ilgi gördüğüne işaret etmektedir. Bu artış, gıda güvenliği, hasat sonrası kayıpların azaltılması, fumigant direnci ve çevre dostu zararlı yönetimi arayışlarının tarımsal araştırmalarda giderek daha görünür hâle gelmesiyle açıklanabilir. Nitekim *S. oryzae*, depolanmış tahıllarda nicel ve nitel kayıplara yol açan önemli zararlılardan biri olarak tanımlanmakta; bu zararlının buğday, arpa, mısır ve sorgum gibi farklı ürünlerde ekonomik kayıplara neden olduğu vurgulanmaktadır (Kandel et al., 2021).



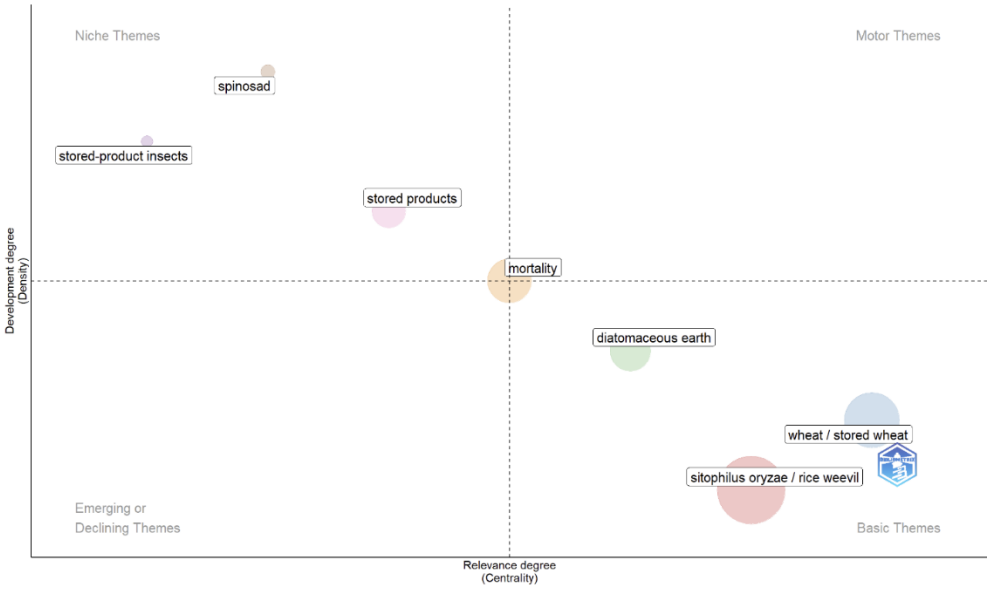
Şekil 6. Yıllık Yayın Üretiminin Yaşam Döngüsü Analizi

Şekil 7. Yıllara Göre Bilimsel Yayın Üretimi

Birleştirilmiş yazar anahtar kelimelerine göre en sık kullanılan 20 anahtar kelime ise Şekil 8'de verilmiştir. Eş anlamlı veya yakın anlamlı terimlerin birleştirilmesinden sonra *S. oryzae* / rice weevil en sık kullanılan anahtar kelime grubu olarak öne çıkmıştır (n = 226). Bunu wheat / stored wheat (n = 160), *Tribolium* spp. (n = 81), *Rhyzopertha dominica* (n = 70) ve diatomaceous earth (n = 66) izlemiştir. Mortality, spinosad, stored-product insects, toxicity, temperature, grain protectants, fumigation, biological control ve repellency gibi terimlerin öne çıkması, literatürün depo zararlıları yönetimi ve kontrol stratejileri etrafında yoğunlaştığını göstermektedir.



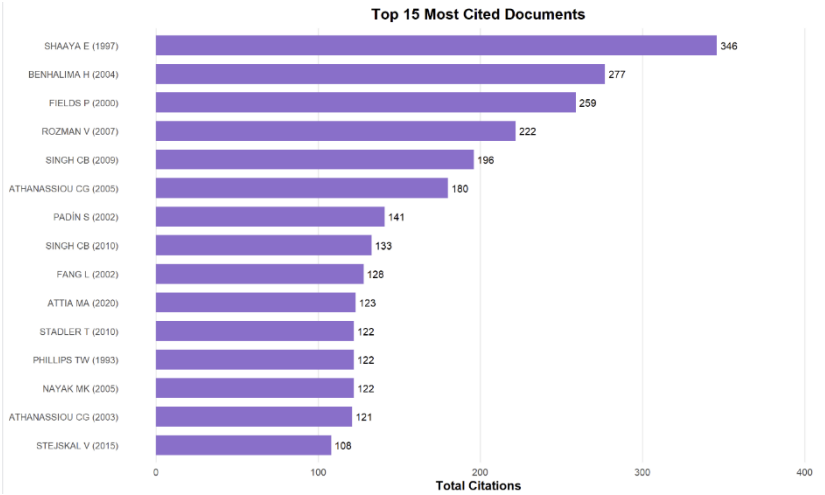
Şekil 8. Birleştirilmiş Yazar Anahtar Kelimelerine Göre En Sık Kullanılan 20 Anahtar Kelime



Birleştirilmiş yazar anahtar kelimelerine dayalı anahtar kelime birlikte-görünüm ağı ise Şekil 9'da verilmiştir. Ağda *S. oryzae* / rice weevil, wheat / stored wheat, *Tribolium* spp., *Rhyzopertha dominica* ve diatomaceous earth düğümlerinin merkezi konumda olduğu görülmektedir. Bu yapı, literatürün temel olarak depo zararlıları, buğdayın depolanması ve zararlı kontrol stratejileri etrafında şekillendiğini göstermektedir. Ayrıca mortality, temperature, toxicity, spinosad, fumigation, grain protectants, biological control ve repellency gibi anahtar kelimelerin ağda yer alması, çalışmaların zararlıların yaşama oranı, insektisit etkinliği ve alternatif mücadele yaklaşımlarına odaklandığını ortaya koymaktadır. Bu bulgu, depolanmış ürün zararlıları literatüründe kimyasal mücadeleden alternatif ve bütünleşik mücadele yaklaşımlarına doğru genişleyen araştırma yönelimiyle uyumludur (Hagstrum et al., 2012; Phillips & Throne, 2010).

Şekil 10, birleştirilmiş yazar anahtar kelimelerine dayalı tematik haritayı göstermektedir. Harita, alanın kavramsal yapısının büyük ölçüde *S. oryzae* / rice weevil, wheat / stored wheat ve diatomaceous earth temel temaları etrafında şekillendiğini göstermektedir. Diyatom toprağının merkezi temalardan biri hâline gelmesi, fosfin ve diğer kimyasal uygulamalara yönelik direnç, kalıntı ve çevresel risk tartışmalarıyla ilişkilidir. Diyatom toprağı, böcek kutikulasındaki mumsu tabakayı aşındırarak dehidrasyona neden olan fiziksel etki mekanizması nedeniyle doğal ve düşük kalıntı riski taşıyan bir mücadele seçeneği olarak ele alınmaktadır (Korunić, 1998). Ancak bu yöntemin etkinliği sıcaklık, bağıl nem, tane nemi, uygulama dozu ve zararlı türüne göre değişebilmektedir (Fields & Korunić, 2000; Yılmaz Doğu & Emekci, 2026). Dolayısıyla diyatom toprağına ilişkin çalışmaların yüksek görünürlüğü, alanın çevre dostu ve sürdürülebilir zararlı yönetimi arayışlarına yöneldiğini göstermektedir.

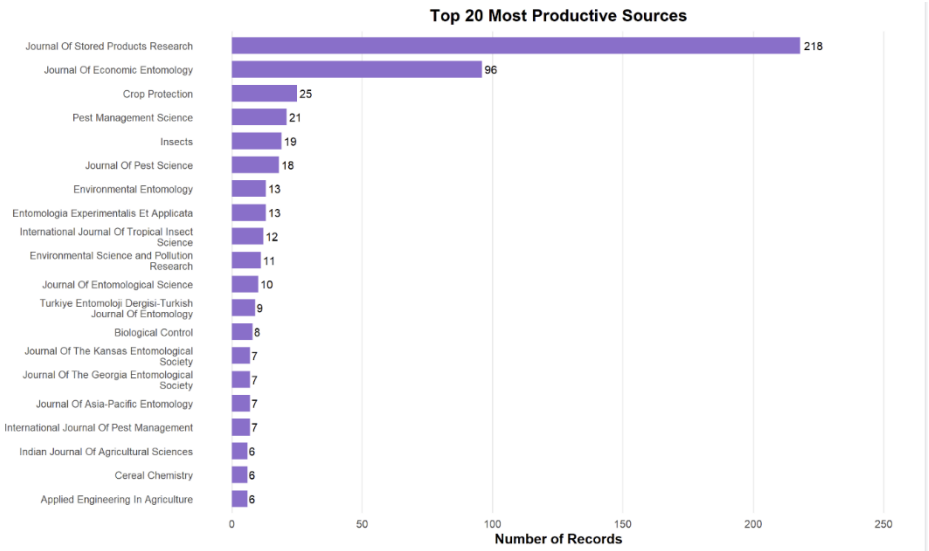
Buna karşılık spinosad, stored-product insects ve stored products niş temalar olarak öne çıkmakta; bu da daha uzmanlaşmış fakat kendi içinde gelişmiş araştırma alanlarına işaret etmektedir. Mortality anahtar kelimesi ise haritanın merkezine yakın konumuyla, tek başına özelleşmiş bir küme oluşturmaktan çok farklı tematik alanlar arasında bağ kuran bir kavram olarak değerlendirilebilir. Genel olarak tematik harita, literatürün depo zararlıları, buğday depolama bağlamı ve zararlı kontrol stratejileri etrafında yapılandığını ortaya koymaktadır.



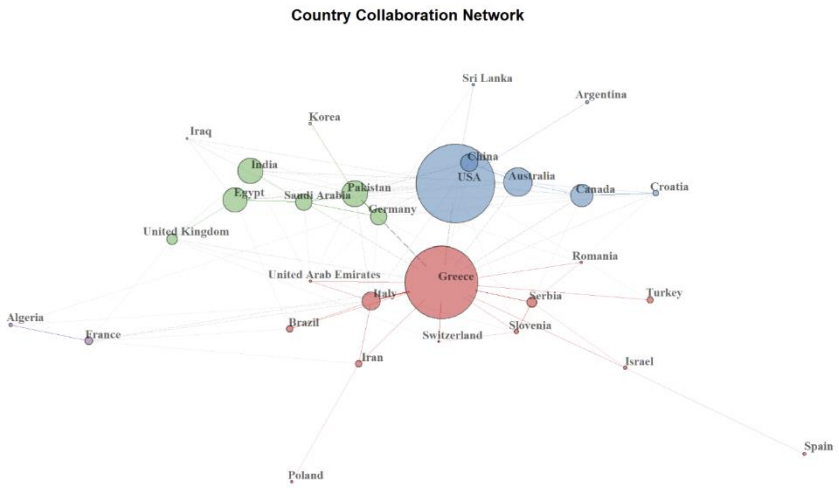
Şekil 9. Birleştirilmiş Yazar Anahtar Kelimelerine Dayalı Anahtar Kelime Birlikte-Görünüm Ağı

Şekil 10. Birleştirilmiş Yazar Anahtar Kelimelerine Dayalı Tematik Harita

En çok atıf alan yayınlara ilişkin bulgular (Şekil 11), literatürde etkili çalışmaların bitkisel yağlar, fosfin direnci, diyatom toprağı, spinosad ve zararlı tespiti gibi konular etrafında yoğunlaştığını göstermektedir. Shaaya ve arkadaşlarının (1997) bitkisel yağların fumigant ve temas etkilerine ilişkin çalışmasının en yüksek atıf (346) alan yayın olması, bitkisel kökenli bileşiklerin depolanmış ürün zararlılarıyla mücadelede uzun süredir ilgi gören bir alternatif olduğunu göstermektedir. Benhalima ve arkadaşlarının (2004) fosfin direnci üzerine çalışmasının yüksek atıf (277) alması ise fumigant direncinin alan için temel sorunlardan biri olduğunu ortaya koymaktadır. Fosfin direncinin küresel ölçekte artması, depolanmış ürün zararlılarıyla mücadelede mevcut uygulamaların sürdürülebilirliğini tehdit eden önemli bir gelişme olarak değerlendirilmektedir (Nayak et al., 2020). Bu bağlamda yüksek atıf alan yayınların tematik dağılımı, alanın yalnızca zararlının biyolojisine değil, etkili, güvenli ve sürdürülebilir kontrol stratejilerine odaklandığını göstermektedir. En çok atıf alan yayınların önemli bir bölümünün Journal of Stored Products Research dergisinde yayımlanmış olması, bu derginin depo zararlıları ve buğday depolama alanındaki etkili çalışmalar için merkezi bir kaynak olduğunu göstermektedir.



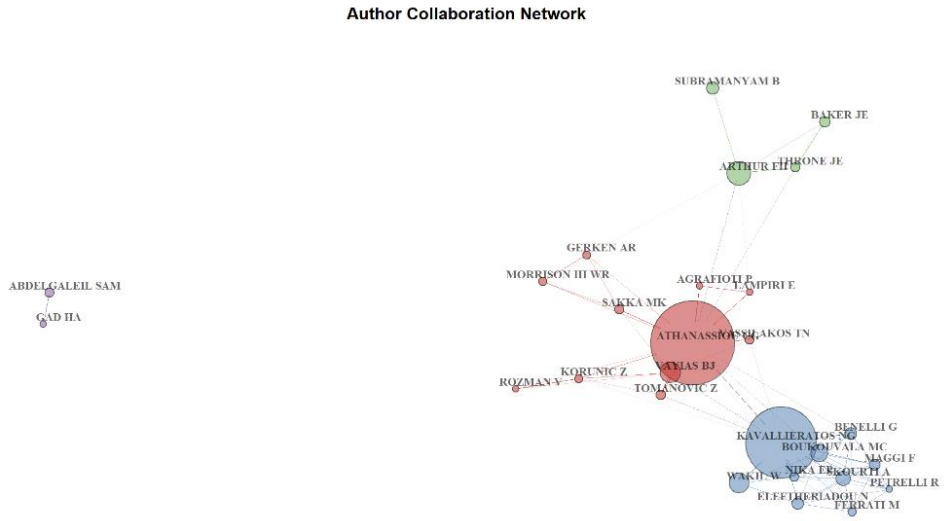
Şekil 11. Web Of Science Toplam Atıf Sayılarına Göre En Çok Atıf Alan 15 Yayın



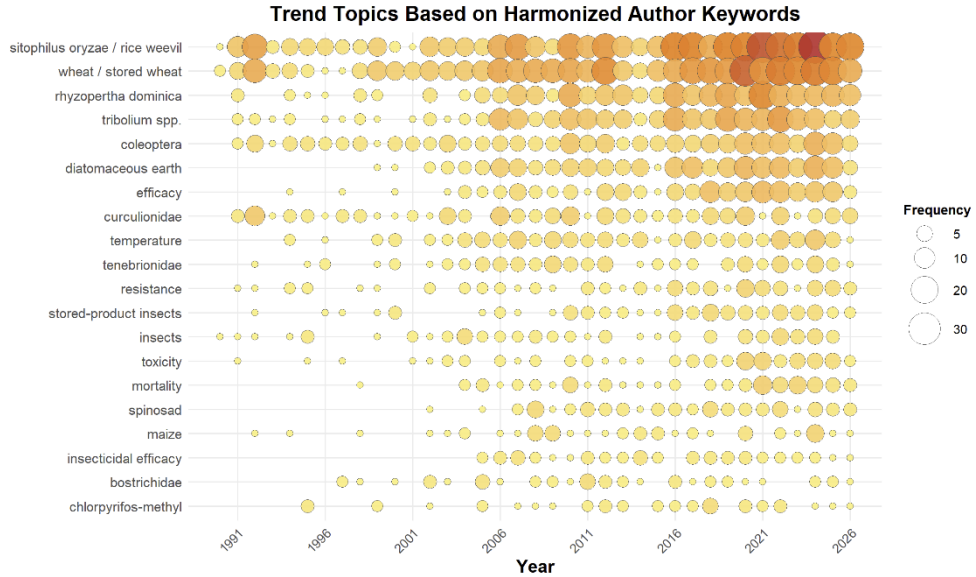
Şekil 12, incelenen literatürde en fazla yayın yayımlayan 20 kaynak/dergiyi göstermektedir. Bulgulara göre Journal of Stored Products Research, 218 kayıtla açık ara en üretken kaynak olarak öne çıkmıştır. Bu dergiyi, 96 kayıtla Journal of Economic Entomology, 25 kayıtla Crop Protection, 21 kayıtla Pest

Management Science ve 19 kayıtla Insects izlemiştir. Bu dağılım, pirinç biti ve buğday ilişkili çalışmaların özellikle depo ürünleri, entomoloji, zararlı yönetimi ve bitki koruma odaklı dergilerde yoğunlaştığını göstermektedir. Ayrıca Journal of Stored Products Research dergisinin yüksek yayın üretimi, bu alan için merkezi bir yayın platformu olduğunu ortaya koymaktadır.

Yazar adreslerinden elde edilen ülke bilgilerine dayalı olarak ülkeler arasındaki ortak yayın ilişkileri ise Şekil 13'te verilmiştir. Ağda ABD ve Yunanistan en büyük ve en merkezi düğümler olarak öne çıkmaktadır. Bu durum, söz konusu iki ülkenin hem yayın üretimi hem de uluslararası iş birlikleri bakımından alanda güçlü bir konuma sahip olduğunu göstermektedir. Avusturalya, Kanada, Çin, Pakistan, Hindistan, Mısır, Sudi Arabistan ve Almanya gibi ülkeler de ağ içinde belirgin bağlantılara sahiptir. Türkiye, ülke üretkenliği analizinde 45 kayıtla ilk 20 ülke arasında yer almasına rağmen, iş birliği ağında daha çevresel bir konumda görünmektedir. Bu bulgu, Türkiye'nin alana görünür bir yayın katkısı sunduğunu; ancak uluslararası ortak yayın ağındaki merkeziliğinin ABD ve Yunanistan gibi öncü ülkeler kadar güçlü olmadığını göstermektedir. Genel olarak ağ yapısı, alanın birkaç merkezi ülke etrafında yoğunlaşan, ancak farklı bölgelerden ülkelerin de dâhil olduğu uluslararası bir iş birliği örüntüsüne sahip olduğunu ortaya koymaktadır.



Şekil 12. En Üretken Kaynaklar/Dergiler



Şekil 13. Ülke İş Birliği Ağı

Yazar iş birliği ağı, alandaki ortak yazarlık ilişkilerini göstermektedir (Şekil 14). Düğümler yazarları, düğüm büyüklüğü yazarın ağ içindeki göreli ağırlığını/üretkenliğini, çizgiler ise yazarlar arasındaki iş birliği bağlantılarını temsil etmektedir. Ağ yapısı, özellikle Athanassiou CG ve Kavallieratos NG etrafında yoğunlaşan iş birliği kümelerinin öne çıktığını göstermektedir. Ayrıca Arthur FH'nin de ayrı bir iş birliği kümesinde önemli bir konuma sahip olduğu görülmektedir. Bulgular, alan yazında iş birliklerinin belirli çekirdek araştırmacılar etrafında kümelendiğini ve ortak yazarlık yapısının sınırlı sayıda güçlü araştırma grubu tarafından şekillendirildiğini ortaya koymaktadır.

Şekil 14. Yazar İş Birliği Ağı

Şekil 15 harmonize edilmiş yazar anahtar kelimelerine dayalı olarak yıllara göre öne çıkan trend konuları göstermektedir. Balonların büyüklüğü ve renk yoğunluğu, ilgili yıldaki anahtar kelime frekansını temsil etmektedir. Bulgular, *S. oryzae* / rice weevil ve wheat / stored wheat terimlerinin alanın süreklilik gösteren temel temaları olduğunu göstermektedir. Bunun yanında *Rhyzopertha dominica*, *Tribolium* spp., Coleoptera, diatomaceous earth, temperature, resistance, mortality, toxicity ve spinosad gibi anahtar kelimelerin özellikle 2000'li yıllardan sonra daha görünür hale geldiği görülmektedir. Bu durum, literatürün depo zararlıları, buğday depolama koşulları, zararlı türleri ve zararlı kontrol stratejileri etrafında geliştiğini ortaya koymaktadır.

Şekil 15. Yıllara Göre Öne Çıkan Anahtar Kelime Eğilimleri

SONUÇ

Bu araştırma, pirinç biti ve buğday ilişkili bilimsel literatürün üretim yapısını, kavramsal gelişimini, atıf örüntülerini ve iş birliği ağlarını bibliyometrik açıdan ortaya koymuştur. Bulgular, alanın uzun bir tarihsel geçmişe sahip olmakla birlikte özellikle 2000'li yıllardan sonra daha görünür hâle geldiğini, 2015 sonrası dönemde ise yayın üretiminin belirgin biçimde hızlandığını göstermektedir. Yaşam döngüsü analizi de alanın henüz doygunluğa ulaşmadığını ve büyüme evresini sürdürdüğünü ortaya koymuştur. Araştırma sonuçları, literatürün temel olarak entomoloji alanında yoğunlaştığını; ancak agronomi, gıda bilimi, bitki bilimleri, çevre bilimleri ve tarımsal araştırmalarla da ilişkili disiplinler arası bir yapıya sahip olduğunu göstermektedir. En üretken yazarlar arasında Athanassiou CG, Kavallieratos NG ve Arthur FH öne çıkarken, Yunanistan ve ABD alanın en görünür ve en merkezi ülkeleri olarak belirlenmiştir. Kurumsal düzeyde University of Thessaly, Agricultural University of Athens ve Benaki Phytopathological Institute'un öne çıkması, alanın özellikle Yunanistan merkezli güçlü bir araştırma hattına sahip olduğunu göstermektedir. Kavramsal ve tematik bulgular, literatürün *S. oryzae*, buğday, depo zararlıları, *Tribolium* türleri, *Rhyzopertha dominica*, diyatom toprağı, mortalite, toksisite, sıcaklık, fumigasyon, spinosad ve direnç gibi temalar etrafında şekillendiğini ortaya koymuştur. En çok atıf alan çalışmaların bitkisel yağlar, fosfin direnci, diyatom toprağı, spinosad ve zararlı tespiti gibi konularda yoğunlaşması, alanın yalnızca zararlının biyolojisine değil, aynı zamanda etkili, sürdürülebilir ve çevre dostu kontrol stratejilerine yöneldiğini göstermektedir. Dergi dağılımı açısından Journal of Stored Products Research, hem yayın sayısı hem de yüksek atıflı çalışmalar bakımından alanın temel yayın platformu olarak öne çıkmıştır. Bu durum, depolanmış ürün zararlıları ve buğday depolama araştırmalarının belirli bir çekirdek dergi etrafında yoğunlaştığını göstermektedir. Ülke ve yazar iş birliği ağları ise alanın birkaç güçlü araştırma grubu ve merkezi ülke etrafında yapılandığını ortaya koymuştur. Türkiye, 45 kayıtla ilk 20 ülke arasında yer alarak alana görünür bir katkı sunmuştur. Bununla birlikte Türkiye'nin uluslararası iş birliği ağında daha çevresel bir konumda kalması, yayın üretiminin uluslararası ortaklıklarla daha fazla desteklenmesi gerektiğini göstermektedir. Bu doğrultuda Türkiye merkezli araştırmaların özellikle direnç izleme, alternatif mücadele yöntemleri, diyatom toprağı, çevre dostu kontrol stratejileri ve karşılaştırmalı saha çalışmaları alanlarında uluslararası ortaklıklarını artırması önerilmektedir. Genel olarak bu araştırma pirinç biti ve buğday ilişkili literatürün büyüyen, entomoloji merkezli fakat disiplinler arası niteliği güçlü bir araştırma alanı olduğunu ortaya koymaktadır. Alanın gelecekte sürdürülebilir depolama uygulamaları, kimyasal olmayan kontrol yöntemleri, erken tespit teknolojileri ve uluslararası araştırma ağları ekseninde gelişmeye devam edeceği öngörülmektedir.

ÖZET

Bu çalışmada, Web of Science (WoS) veri tabanında 1976-2026 yılları arasında indekslenen makarna konulu bilimsel yayınların bibliyometrik analizi gerçekleştirilerek, alandaki bilimsel gelişimin ve araştırma eğilimlerinin ortaya konulması amaçlanmıştır. Bibliyometrik analiz sonucunda, 779 farklı kaynakta yayımlanmış toplam 2.825 belge belirlenmiş ve yıllık bilimsel üretim artış oranının %10,4 olduğu tespit edilmiştir. Belge başına ortalama atıf sayısı 23,4, ortalama belge yaşı ise 11,4 yıl olarak belirlenmiştir. Literatüre toplam 8.911 yazar katkıda bulunmuş ve belge başına ortalama ortak yazar sayısı 4,8 olarak hesaplanmıştır. Yayınların %22,7'inde uluslararası ortak yazarlık bulunması, alandaki araştırmaların önemli ölçüde uluslararası iş birliği ile yürütüldüğünü göstermektedir. Veri setinde 5.823 yazar anahtar kelimesi ve 4.343 Keywords Plus terimi belirlenmiş olup, bu durum makarna araştırmalarının geniş ve çok yönlü bir konu alanına sahip olduğunu ortaya koymaktadır. Genel olarak bulgular, makarna araştırmalarının son beş on yılda istikrarlı biçimde büyüyen, yüksek düzeyde iş birliğine dayalı ve geniş bir bilimsel kapsama sahip bir araştırma alanı olduğunu göstermektedir. Elde edilen bibliyometrik profil, bu alandaki bilimsel gelişimin genel görünümünü sunmakta ve başlıca araştırma eğilimleri ile yeni ortaya çıkan konuların belirlenmesine temel oluşturmaktadır.
Anahtar kelimeler: Makarna, bilimsel üretim, araştırma eğilimleri

ABSTRACT

This study aimed to evaluate the global research landscape and scientific trends in pasta / macaroni research through a bibliometric analysis of publications indexed in the Web of Science (WoS) database between 1976 and 2026. The bibliometric analysis identified 2,825 documents published across 779 sources, with an annual growth rate of 10.4%, indicating a substantial and continuing expansion of research activity in this field. The documents received an average of 23.4 citations per publication and had a mean document age of 11.4 years. A total of 8,911 authors contributed to the literature, with an average of 4.8 co-authors per document, while 22.7% of publications involved international co-authorship. The dataset included 5,823 authors' keywords and 4,343 Keywords Plus terms, reflecting a broad range of research topics associated with macaroni and pasta. Overall, the findings demonstrate a steadily growing and highly collaborative research field, with considerable scientific output and increasing international collaboration. The bibliometric profile provides an overview of the development and scope of research on macaroni and pasta over the past five decades and offers a basis for identifying major research trends and emerging topics in this field.
Keywords: Macaroni, scientific production, research trends

GİRİŞ

Makarnanın kökenine ilişkin farklı görüşler bulunmakla birlikte, genel kabul gören yaklaşım, bu ürünün belirli bir kişi veya kültür tarafından tek başına icat edilmediği ve yalnızca bir ulusa ait bir ürün olarak değerlendirilmemesi gerektiğidir. Aksine, makarna farklı coğrafyalarda ve uygarlıklarda zaman içerisinde gelişerek şekillenen çok katmanlı bir tarihsel sürecin ürünü olarak değerlendirilmektedir. Tarihsel kaynaklar, makarnaya veya makarna benzeri hamur ürünlerine ilişkin izlerin Etrüskler, Romalılar, Araplar ve Çinliler başta olmak üzere farklı uygarlıklarda bulunduğunu göstermektedir. Özellikle MS 960-1280 yılları arasında Çin'de makarnaya benzer ürünlerin tüketildiğine ilişkin kayıtlar bulunmakta ve bu ürünlerin Marco Polo'nun Çin seyahati sonrasında Avrupa'ya, özellikle İtalya'ya taşındığı yönünde yaygın bir görüş bulunmaktadır (Yargun, 2025). Makarna, Akdeniz diyetinin temel gıdalarından biri olup farklı yaş ve sosyoekonomik gruplardan insanlar tarafından yaygın olarak tüketilmektedir. Yaygın tüketiminde; uzun raf ömrü, uygun fiyatı, hazırlanmasının kolay ve pratik

olması, kullanım kolaylığı ve dünya genelinde kolaylıkla ulaşılabilir olması gibi çeşitli avantajları etkili olmaktadır (Taşcı ve ark., 2023).

Türkiye makarna sektörü, yüksek üretim kapasitesi ve ihracat potansiyeli ile ülke tarım ve gıda sanayisinin önemli sektörlerinden biridir. Ülkemizde toplam 2,8 milyon ton/yıl üretim kapasitesine sahip 26 makarna fabrikası faaliyet göstermekte; sektörde yaklaşık 10 bin kişi doğrudan, 100 bin kişi ise dolaylı olarak istihdam edilmektedir. Türkiye, makarna üretiminde dünya genelinde genellikle ikinci sırada yer almaktadır (TMSD, 2022; Taşcı ve ark., 2022). Nitekim, 2010 yılında yaklaşık 734.159 ton olan Türkiye'nin makarna üretimi, 2025 yılında 2.071.584 tona ulaşarak önemli bir artış göstermiştir (TÜİK, 2026).

Türkiye, makarna ihracatında da küresel ölçekte önemli bir konuma sahiptir. 2026 yılı verilerine göre Türkiye, yaklaşık 1,4 milyon tonluk makarna ihracatı ile 2,6 milyon ton ihracat gerçekleştiren İtalya'nın ardından dünya genelinde ikinci sırada yer almaktadır. Türkiye'de üretilen makarna, başta Afrika ve Asya ülkeleri olmak üzere 165 ülkeye ihraç edilmektedir. İhracatın gerçekleştirildiği başlıca ülkeler Gana (166 bin ton), Somali (162 bin ton), Togo (114 bin ton), Benin (102 bin ton) ve Japonya (75 bin ton) olup, diğer ülkeler de önemli bir pazar payına sahiptir (TradeMap, 2026). Bu veriler, Türkiye makarna sektörünün yalnızca üretim kapasitesi açısından değil, aynı zamanda uluslararası ticaretteki etkinliği ve geniş ihracat ağı bakımından da önemli bir konuma sahip olduğunu göstermektedir.

Makarna, günlük beslenmede yaygın olarak tüketilen temel gıda ürünlerinden biridir (Taşçı ve ark., 2023). Kişi başına yıllık makarna tüketimi açısından İtalya, 23,5 kg ile ilk sırada yer alırken, Tunus 17 kg ile ikinci, Türkiye ise 7,53 kg ile 14. sırada yer almaktadır (IPO, 2022). Türkiye'de makarna tüketiminin 14. sırada yer almasının başlıca nedenlerinden biri, makarnaya alternatif olarak tüketilen ve makarnalık buğdaydan üretilen ve geleneksel bir ürün olan bulgurun yaygın tüketimidir. Bununla birlikte, Türkiye'de makarna tüketimi her geçen yıl artış göstermektedir (Taçcı ve ark., 2023).

Türkiye, özellikle Güneydoğu Anadolu Bölgesi, topografik özellikleri, toprak yapısı ve sahip olduğu geleneksel tarım nedeniyle makarnanın temel hammaddesi olan makarnalık buğdayının yetiştirilmesi için uygun koşullara sahiptir. Makarna, *Triticum durum* buğdayının uygun koşullarda öğütülmesiyle elde edilen irmiğin su ile yoğrulması, farklı şekiller verilmesi ve kurutulmasıyla üretilen yarı hazır bir gıda ürünüdür (Muslu ve ark., 2021). Yapısında bulunan kompleks karbonhidratların hızlı bir şekilde enerjiye dönüştürülebilmesi, vitamin ve mineraller bakımından zengin olması ve yüksek enerji değerine sahip bulunması nedeniyle önemli bir besin kaynağı olarak değerlendirilmektedir (Demirkol ve İçöz, 2002).

Son yıllarda bibliyometrik teknikler, araştırma eğilimlerini ortaya koymak, bilgi boşluklarını belirlemek ve gelecekteki bilimsel ve politika önceliklerine yön vermek amacıyla tarım ve gıda bilimlerinde giderek daha fazla kullanılmaktadır (Giraldo ve ark., 2019). Bibliyometrik analiz; yazar ve kurum bilgileri, atıf sayıları ve anahtar kelime birliktelikleri gibi yayın üst verilerinden yararlanarak bilimsel araştırmaları, yayın çıktıları, atıf ağları ve iş birliği örüntüleri üzerinden nicel olarak değerlendiren bir yöntemdir (Aria ve Cuccurullo, 2017; Yuan ve Sun, 2022). Bu yaklaşım, belirli bir alandaki bilginin yapısı ve dinamikleri hakkında önemli bilgiler sunarak etkili yazar, kurum ve ülkelerin belirlenmesine; bilgi boşluklarının, yeni ortaya çıkan araştırma konularının ve gelecekteki araştırma yönelimlerinin ortaya konulmasına olanak sağlamaktadır (Liaqat ve ark., 2025).

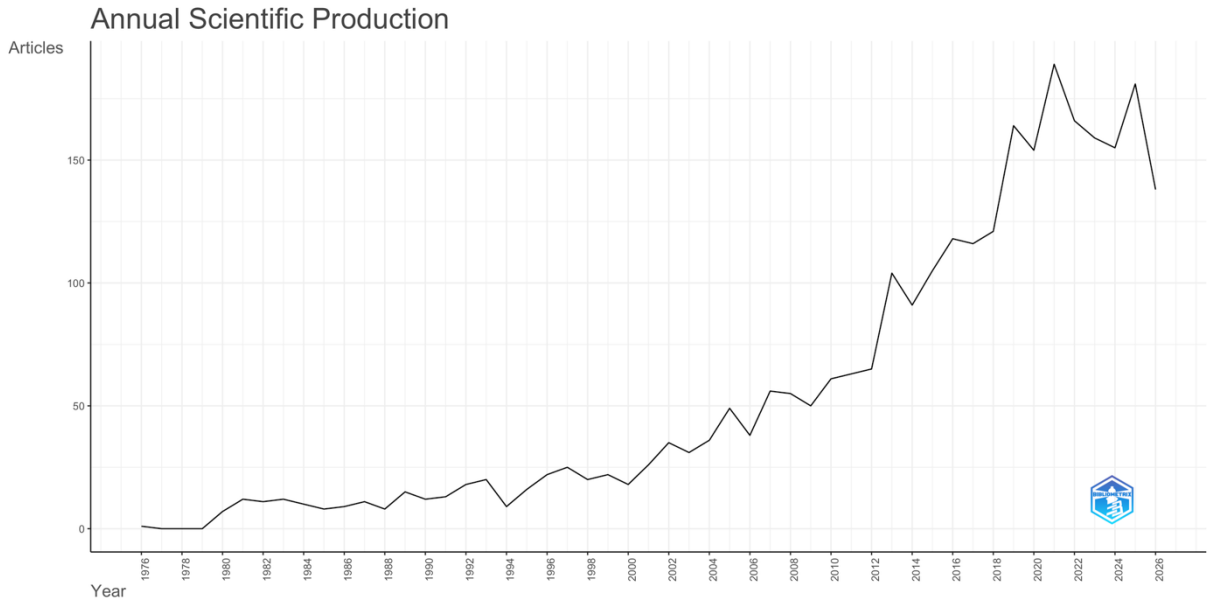
Web of Science (WoS) Core Collection, dergilerin titiz seçim süreçlerinden geçirilmesi ve standartlaştırılmış indeksleme sistemi nedeniyle bibliyometrik araştırmalarda en güvenilir ve kapsamlı veri tabanlarından biri olarak kabul edilmektedir (Birkle ve ark., 2020). Bu çalışmanın amacı, 1976-2026 yılları arasında makarna konusunda yayımlanan bilimsel literatürü bibliyometrik açıdan analiz ederek araştırma eğilimlerini, öne çıkan araştırmacıları, kurumları, ülkeleri, dergileri ve tematik araştırma alanlarını ortaya koymaktır. Elde edilen bulguların, gelecekteki araştırma yönelimlerinin belirlenmesine katkı sağlamasının yanı sıra sürdürülebilir, verimli ve yüksek kaliteli makarna değer zincirlerinin geliştirilmesine yönelik bilimsel çalışmalara temel oluşturması hedeflenmektedir.

YÖNTEM

Bu çalışmada kullanılan bibliyometrik veriler; Science Citation Index (SCI) Expanded ve Emerging Sources Citation Index (ESCI) dizinlerini kapsayan WoS Core Collection'dan elde edilmiştir. WoS'un kökeni, Eugene Garfield tarafından kurulan Institute for Scientific Information'ın (Bilimsel Bilgi Enstitüsü) başlangıçta bir bilgi erişim aracı olarak Science Citation Index'i ticari kullanıma sunduğu 1964 yılına dayanmaktadır. SCI, Social Sciences Citation Index ve Arts & Humanities Citation Index

ile birleştirilerek 1997 yılında World Wide Web üzerinde Web of Science adıyla kullanıma sunulmuş ve platform günümüzde Clarivate Analytics tarafından işletilmektedir (Birkle ve ark., 2020). Makro düzeyde güvenilir bilimsel ölçüm (scientometric) veya bibliyometrik analizler sunmasıyla tanınan bu platform, köklü uygulamalara dayanan güçlü indeksleme standartlarına sahip olduğunu ortaya koymaktadır (Birkle ve ark., 2020; Raj ve Sahoo, 2024).

Bu araştırma kapsamındaki veriler, ilk olarak WOS veri tabanına girilerek çalışmaların başlığında "pasta" OR "macaroni" OR "spaghetti" anahtar kelimeleri kullanılarak, bu ifadelerden birini içeren çalışmalar 15.09.2026 tarihi itibarıyle araştırılmıştır. Bu arama sonucunda başlangıçta 3.666 kayıt elde edilmiştir. Bu kayıtlar daha sonra birbirini izleyen filtreleme aşamalarıyla daraltılmıştır. 2027 tarihli kayıtların (analiz 1976-2026 dönemini kapsamaktadır) hariç tutulmasıyla geriye 3.665 kayıt kalmıştır. Yalnızca araştırma makalelerini kapsayacak şekilde belge türüne göre yapılan filtreleme veri setini 2.947 kayda düşürmüştür. Aramanın İngilizce yazılmış makalelerle sınırlandırılması ise veri setini 2.825 kayda indirmiş ve nihai veri seti oluşturulmuştur. Elde edilen meta veriler BibTeX formatında dışa aktarılmış ve ardından R Studio yazılımında (version 4.4.2) Bibliometrix paketi Biblioshiny grafik arayüzü kullanılarak işlenmiştir (Aria ve Cuccurullo, 2017).



ARAŞTIRMA BULGULARI VE TARTIŞMA

Konu taraması sonucunda WoS veritabanından elde edilen makalelere yapılan tanımlayıcı analiz sonucunda belirlenen koleksiyona ait temel bilgiler Tablo 1'de verilmiştir.

Tablo 1. Koleksiyona Ait Tanımlayıcı Analiz

Veriler Hakkında Ana Bilgiler	
Zaman Aralığı	1976 : 2026
Kaynaklar (Dergi, Kitap vb.)	779
Makale Sayısı	2.825
Yıllık Büyüme Oranı (%)	10,4
Belgelerin Ortalama Yaşı	11,4
Belge Başına Ortalama Atıf	23,4
Referans Sayısı	65.105
Yazarlar	
Yazar	8.911
Tek Yazarlı Belge	163
Belge Başına Ortak Yazar	4,8
Uluslararası Ortak Yazarlıklar (%)	22,7

Web of Science veri tabanında bibliyometrik analizi sonucunda toplamda 2.825 adet araştırma makalesi elde edilmiştir (Tablo 1). Şekil 1'de makarna konusunda 1976-2026 yılları arasında gerçekleştirilen bilimsel çalışmaların yıllık değişimi verilmiştir. Grafik verileri incelendiğinde, konuyla ilgili yayın sayısının yıllar içinde genel olarak artan bir seyir izlediği görülmektedir. 1970'li ve 1980'li yıllarda yıllık çalışma sayısı oldukça düşük düzeylerde kalırken, özellikle 2010'lu yıllardan itibaren makarna ile ilgili akademik araştırmalarda çok hızlı bir artış yaşanmıştır. Çalışma sayısındaki en yüksek artış 2021 yılında gerçekleşmiş ve yıllık makale sayısı zirve noktasına ulaşmıştır. Son yıllarda gözlenen bu belirgin artış, makarnanın besinsel içeriğinin geliştirilmesi, zenginleştirilmiş/fonksiyonel makarna üretimi, glutensiz alternatifler ve yeni işleme teknolojileri gibi konulara olan akademik ve endüstriyel ilginin artmasıyla açıklanabilir. Benzer şekilde, Cecchini ve ark. (2020), makarnalık buğday ve makarna üzerine yaptıkları karşılaştırmalı bibliyometrik analizde, özellikle 2004 yılından itibaren yayın sayısında önemli bir artış olduğunu bildirmişlerdir; bu süreçte en erken çalışmalar genetik ve temel kalite özelliklerine odaklanırken, orta dönemdeki araştırmalar işleme, beslenme ve güvenliğe doğru genişlemiş, en güncel çalışmalar ise tüketici odaklı duyusal ve dokusal özelliklere yoğunlaşmıştır.

Şekil 1. Makarna ilgili olarak yapılan çalışmaların yıllık değişimi

Bu konuda yapılan çalışmaların yıllık büyüme oranı %10,4 olup, belgelerin ortalama yaşı ise 11,4'tür (Tablo 1). Çalışmada 172 WoS kategorisi, 110 çalışma alanı tespit edilmiştir. 1976-2026 yılları arasında yapılan çalışmaların WoS kategorilerine ve araştırma alanlarına göre ilk 20'si Tablo 2'de verilmiştir. Tablo 2 incelendiğinde, Food Science Technology'nin hem WoS kategorisinde hem de araştırma alanında 1497 makale ve %53'lük oranla ilk sırada yer aldığı görülmüştür. WoS kategorilerilerinde Chemistry Applied (%10,7) ve Nutrition Dietetics (%8,5); Araştırma Alanlarında ise Physics (%16,6) ve Chemistry (%14,4) öne çıkan başlıca disiplinler olmuştur. Elde edilen bu dağılım, makarna konusundaki akademik çalışmaların temel olarak ürün geliştirme, gıda kimyası ve besleyici değer üzerine yoğunlaştığını göstermektedir. Ayrıca Tarım, Kimya Mühendisliği, Biyokimya ve Biyoteknoloji gibi alanların da listede üst sıralarda yer alması, konunun tarladan sofraya uzanan zincirde disiplinlerarası bir yaklaşımla ele alındığını ortaya koymaktadır. Benzer şekilde Yuan ve Sun (2022), buğday araştırmalarının 78 WoS konu kategorisi ve 55 araştırma alanını kapsadığını tespit etmiştir. En öne çıkan kategori Plant Sciences olup, bunu Agronomy, Food Science & Technology, Multidisciplinary/General Science ve Environmental Sciences takip etmiştir. Araştırma alanlarında ise liderliği Plant Sciences ve Agriculture alırken, bunları Science & Technology - Other Topics, Environmental Sciences/Ecology ve Food Science & Technology izlemiştir.

Tablo 2. En iyi 20 WoS kategorisi ve araştırma alanı, 1976-2026

Sıra	WoS Kategorisi	Makale Sayısı	% Oranı	Araştırma Alanı	Makale Sayısı	% Oranı
1	Food Science Technology	1497	53,0	Food Science Technology	1497	53,0
2	Chemistry Applied	301	10,7	Physics	468	16,6
3	Nutrition Dietetics	240	8,5	Chemistry	408	14,4
4	Physics Mathematical	184	6,5	Nutrition Dietetics	240	8,5
5	Physics Multidisciplinary	145	5,1	Agriculture	195	6,9
6	Physics Fluids Plasmas	119	4,2	Engineering	139	4,9
7	Agriculture Multidisciplinary	99	3,5	Mathematics	116	4,1
8	Mathematics Applied	93	3,3	Biochemistry Molecular Biology	101	3,6
9	Biochemistry Molecular Biology	85	3,0	Environmental Sciences Ecology	88	3,1

10	Physics Nuclear	80	2,8	Science Technology Other Topics	88	3,1
11	Engineering Chemical	74	2,6	Biotechnology Applied Microbiology	58	2,1
12	Chemistry Multidisciplinary	72	2,5	Materials Science	53	1,9
13	Physics Applied	59	2,1	Mechanics	44	1,6
14	Biotechnology Applied Microbiology	58	2,1	Zoology	41	1,5
15	Agronomy	56	2,0	Microbiology	35	1,2
16	Multidisciplinary Sciences	54	1,9	Astronomy Astrophysics	29	1,0
17	Materials Science Multidisciplinary	49	1,7	Plant Sciences	28	1,0
18	Mechanics	44	1,6	Computer Science	27	1,0
19	Environmental Sciences	42	1,5	Toxicology	24	0,8
20	Ecology	40	1,4	Optics	23	0,8

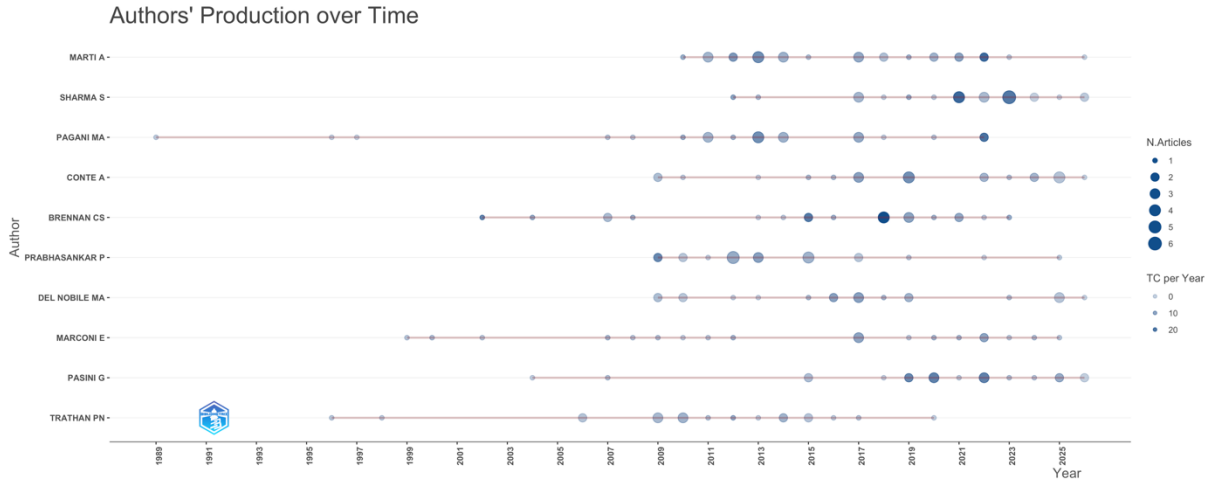
Yayınlarda en çok kullanılan anahtar kelimelerin ağaç haritası (tree-map) analizi sonuçları Şekil 2'de sunulmuştur. Analiz sonuçlarına göre, literatürde en yüksek frekansa sahip olan temel kavramlar sırasıyla 'pasta' (%9), 'quality' (%8), 'spaghetti' (%5), 'starch' (%4), 'flour' (%4) ve 'cooking quality' (%4) olarak öne çıkmıştır. Tree-map haritasındaki kelime dağılımı incelendiğinde akademik odağın üç ana eksende yoğunlaştığı görülmektedir: İlk olarak, makarnanın tekstürel yapısı ve pişme özellikleri araştırmaların temel dayanağını oluşturmaktadır. İkinci olarak, fonksiyonel gıda geliştirme trendine paralel biçimde besinsel değerler (lif içeriği, antioksidan aktivite, sindirilebilirlik, glisemik indeks, polifenoller) ve glutensiz formülasyonlar sıklıkla çalışılan konular arasında yer almıştır. Son olarak, hammadde özellikleri ve proses teknolojileri kapsamında buğday, durum buğdayı, irmik, hamur reolojisi ve ekstrüzyon prosesi teknolojik açıdan yoğun incelenen parametreler olmuştur.

Şekil 2. Yayınlarda en çok rastlanan anahtar kelimelerin tree-map analizine ait görsel

Makarna ile ilgili olarak yapılan araştırma makalelerinin yayınlandığı dergilere bakıldığında, bu 2,825 araştırma makalesinin WoS veri tabanında taranan 779 farklı dergide yayınlandığı (Tablo 1), bu dergilerden 478 tanesinde sadece bir makale yayınlanırken, 301 dergide ise iki veya daha fazla makale yayınlandığı belirlenmiştir.
En fazla makalenin yayınlandığı dergi 128 makale ile Foods olurken, bunu LWT-Food Science and Technology (117), Food Chemistry (101), International Journal of Food Science and Technology (78), Physical Review E (77) ve diğer degiler takip etmiştir (Tablo 3).

Tablo 3. Makarna ile ilgili makalelerin yayınlandığı önemli dergiler

Kaynak	**Makale Sayısı**
Foods	128
LWT-Food Science and Technology	117
Food Chemistry	101
International Journal of Food Science and Technology	78
Physical Review E	77
Cereal Chemistry	74
Journal of Cereal Science	64
Physical Review C	59
Journal of Food Science	50
Journal of Food Processing and Preservation	45
Diğer Dergiler	2,032
Toplam	**2,825**



Bu çalışmaya konu olan makaleler incelendiğinde, ilk makalenin yayınlandığı 1976 yılından bu yana 163 tanesi tek isimli makale olmak üzere toplam 2.825 makalede 8.911 yazarın yer aldığı çalışma yayınlanmıştır. Makale başı yazar sayısı 4,8 olup, uluslararası iş birliği yapılan ortak yazarlı makale oranı %22,7 olmuştur (Tablo 1). Önceki çalışmalar, uluslararası iş birliğinin bilimsel çıktıların görünürlüğünü ve etkisini artırdığını göstermiştir (Donthu ve ark., 2021).
Makarna konusunda en fazla yayın üreten araştırmacılara ait veriler Tablo 4'te sunulmuştur. Veriler incelendiğinde, literatürde en yüksek makale sayısına sahip araştırmacının 28 yayın ile Marti A olduğu görülmektedir. Marti A'yı sırasıyla Sharma S (26 makale), Pagani Ma (24 makale), Conte A (23 makale), Brennan Cs (22 makale) ve Prabhasankar P (22 makale) izlemiştir.

Tablo 4. Makarna ile ilgili en fazla çalışması bulunan yazarlar

Yazar	**Makale Sayısı**	**Yazar**	**Makale Sayısı**
Marti A	28	Wojtowicz A	17
Sharma S	26	Bello-Perez La	16
Pagani Ma	24	Singh B	16
Conte A	23	Ponno A	15
Brennan Cs	22	Williams Td	15
Prabhasankar P	22	Fares C	14
Del Nobile Ma	20	İametti S	14
Marconi E	20	Micard V	14
Pasini G	20	Ruffo S	14
Trathan Pn	20	A. A	13
Manthey Fa	19	Carini E	13
Brennan Ma	18	Cimini A	13
Giuberti G	18	Horowitz Cj	13

Sobota A	18	Menezes Dp	13
Vittadini E	17	Simonato B	13

En üretken araştırmacıların zaman içindeki yayın performansları ve aldıkları atıf durumları Şekil 3'te verilmiştir. Grafikte yer alan dairelerin büyüklüğü ilgili yıldaki makale sayısını, rengin koyuluğu ise yıllık ortalama atıf sayısını göstermektedir. Bulgular incelendiğinde, Pagani MA'nın 1980'lerin sonundan günümüze kadar uzanan yayın geçmişiyle alandaki en kıdemli araştırmacılardan biri olduğu görülmektedir. Marti A ve Conte A gibi isimlerin özellikle 2010 sonrasında istikrarlı bir yayın çizgisine sahip oldukları göze çarpmaktadır. Etki boyutu (atıf oranı) açısından bakıldığında, Brennan CS'nin 2018 yılındaki yayınlarının ve Sharma S'nin 2021 ile 2023 yıllarındaki çalışmalarının yüksek atıf oranlarıyla öne çıktığı tespit edilmiştir. Araştırmacıların zamansal dağılımı, makarna alanındaki bilimsel üretimin 2010 yılından itibaren hem nitelik hem de nicelik yönünden ivme kazandığını doğrulamaktadır.

Şekil 3. Yazarların makarna ile ilgili çalışmalarının zaman içindeki üretimi

Bu 2.825 araştırma makalesi küresel olarak 66.062 atıf almış olup, makale başına ortalama atıf sayısı ise 23,4'tür (Tablo 1). Makarna ile ilgili yapılan makaleler atıf sayısına göre sıralandığı zaman; en fazla atıf 417 adet ile Tudorica CM'nin 2002 yılında yaptığı çalışmaya yapılmıştır. Bu çalışmayı, 401 adet atıf ile Walsh I (2014), 316 adet atıf ile Petittot M (2010), 316 adet atıf ile Mirarab S (2015), 285 adet atıf ile Ajila SM (2020) ve diğerleri takip etmiştir (Tablo 5).

Tablo 5. Makarna ile ilgili yapılan makalelerin aldığı küresel atıf sayısı

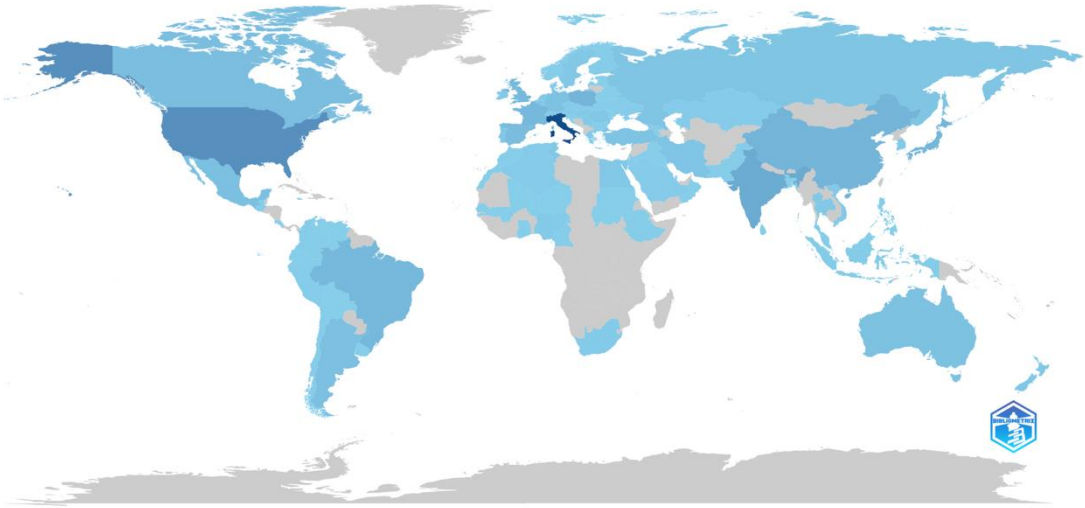
Bibliyometrik analiz sonucunda en çok atıf alan yazarlara ait bilgiler aşağıda verilmiştir (Tablo 6). Makarna alanında yapılan çalışmalarda en fazla atıf alan araştırmacılara ait veriler incelendiğinde, Marti A'nın 362 atıf ile listenin ilk sırasında yer aldığı görülmektedir. Marti A'yı sırasıyla Pagani MA (346 atıf), Brennan CS (326 atıf), Petitot M (255 atıf) ve Horowitz CJ (254 atıf) izlemektedir. Yazarların atıf sayılarına göre dağılımı, ilk sıralarda yer alan araştırmacıların çalışmalarının alandaki diğer bilim insanları tarafından sıklıkla referans gösterildiğini ve makarna literatürünün metodolojik ve teorik çerçevesinin şekillenmesinde bu kilit isimlerin belirleyici bir rol oynadığını ortaya koymaktadır.



Tablo 6. En çok atıf alan 20 yazar sıralaması

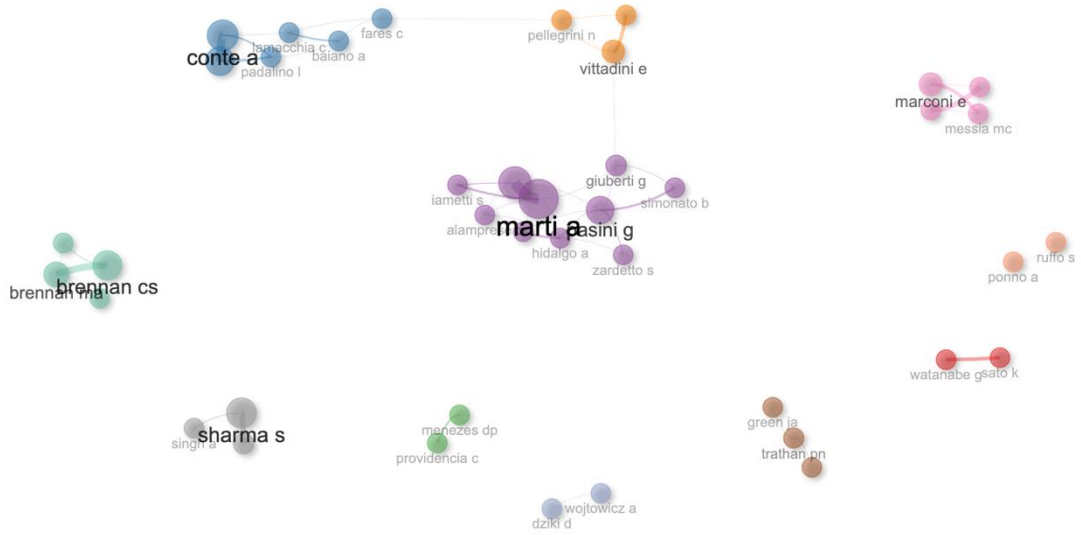
Yazar	Atıf Sayısı	Yazar	Atıf Sayısı
Marti A	362	Marconi E	188
Pagani MA	346	Micard	184
Brennan CS	326	Valerıe V	184
Petitot M	255	Fares C	177
Horowitz CJ	254	Simonato B	171
Prabhasankar P	208	Barron C	168
Brennan MA	201	Bello-Perez LA	167
Micard V	199	Ruffo S	162
Iametti S	197	Degidio MG	161
Pasini G	192	Mariani BM	161

Sorumlu yazarların ülkeleri, makale sayıları, tüm makaleler arasındaki oranı ile tek veya çok ülke yazarlı makale sayısına ilişkin veriler Tablo 7 ve Şekil 4'te sunulmuştur. Elde edilen bulgular doğrultusunda, makarna konusundaki bilimsel üretimin %22,5'ini (637 makale) tek başına gerçekleştiren İtalya'nın alanda küresel bir lider konumunda olduğu görülmektedir. İtalya'yı sırasıyla ABD (298 makale, %10,5), Hindistan (193 makale, %6,8) ve Çin (110 makale, %3,9) izlemektedir.

Tablo 7. Sorumlu yazarların ülkeleri, makale sayıları, tüm makaleler arasındaki oranı ile tek veya çok ülke yazarlı makale sayısı

	Makale Sayısı	Toplam Makale Sayısına Oranı (%)	Tek Ülke Yazarlı Makale Sayısı	Çok Ülke Yazarlı Makale Sayısı
İtalya	637	22,5	520	117
ABD	298	10,5	235	63
Hindistan	193	6,8	172	21
Çin	110	3,9	82	28
Polanya	108	3,8	85	23
Birleşik Krallık	99	3,5	76	23
Brezilya	95	3,4	77	18
Fransa	95	3,4	71	24
Kanada	82	2,9	62	20
İspanya	73	2,6	36	37
Japonya	66	2,3	51	15
Almanya	64	2,3	38	26
Meksika	61	2,2	39	22
Arjantin	57	2,0	50	7
Türkiye	54	1,9	54	0
Avustralya	51	1,8	32	19
Rusya	42	1,5	35	7
İran	34	1,2	28	6
Romanya	33	1,2	30	3
Yeni Zelanda	30	1,1	17	13

Şekil 4. Ülkelerin makale sayılarına ait görsel (mavilik arttıkça makale sayısı artmaktadır)

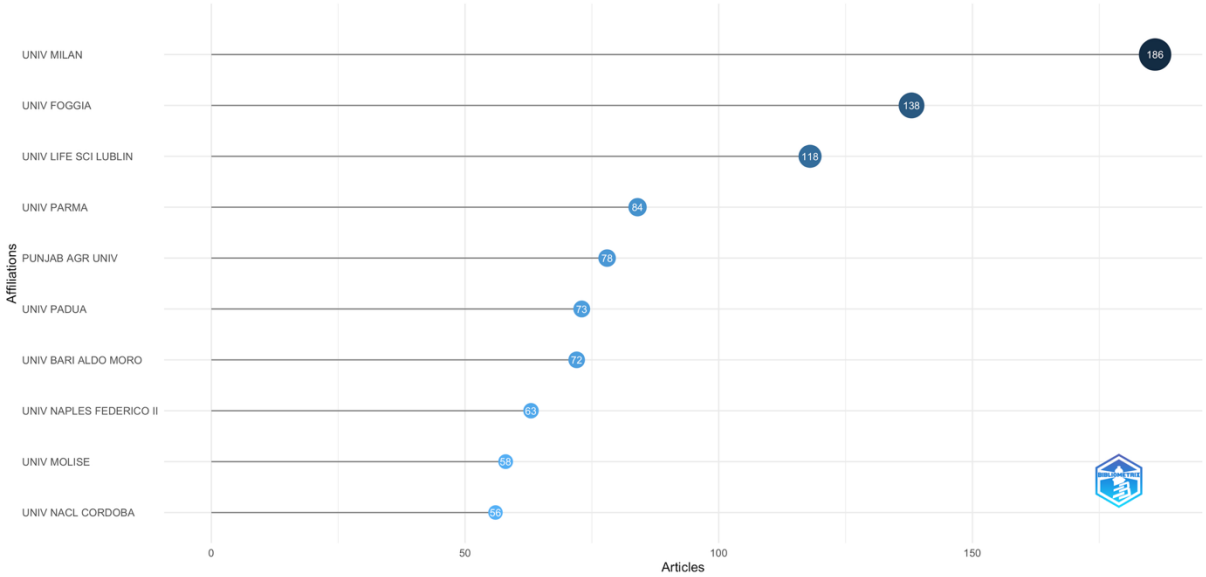


Ülkelerin uluslararası bilimsel iş birliği kapasiteleri değerlendirildiğinde, İtalya 117 çok ülke yazarlı makale ile ilk sırada yer alırken, İspanya toplam yayınlarının yaklaşık yarısını uluslararası ortaklıklarla yürüterek iş birliği oranı en yüksek ülkelerden biri olmuştur. Türkiye ise 54 makale (%1,9) ile 15. sırada

yer almakta olup, çalışmalarının tamamının tek ülke yazarlı olması ülkemizin bu alanda uluslararası araştırma ağlarına entegrasyonunu artırması gerektiğine işaret etmektedir (Tablo 7, Şekil 5).

Şekil 5. Sorumlu yazarların ülkeleri, makale sayıları, tek veya çok ülke yazarlı makale sayısı

Sorumlu yazarlar arasındaki iş birliği ağını gösteren harita Şekil 6'da sunulmuştur. Ağ haritasındaki renkli kümeler birlikte çalışan araştırma gruplarını, halka büyüklükleri yayın ağırlığını, bağlantı çizgileri ise yazarlar arasındaki ortak yayın ilişkilerini temsil etmektedir. Bulgular incelendiğinde, literatürdeki iş birliği ağının en güçlü ve merkezi kümesini Marti A ve Pasini G etrafında toplanan grubun (Iametti S, Giuberti G, Simonato B vb.) oluşturduğu görülmektedir. Bunun yanı sıra Conte A liderliğindeki küme ile Brennan CS merkezli araştırma grupları da alandaki diğer belirgin iş birliği odakları olarak öne çıkmaktadır. Genel olarak değerlendirildiğinde ise, makarna konusundaki yazarlık ağlarının tek bir küresel merkez yerine, belirli araştırmacıların liderliğinde şekillenen çok sayıda bağımsız ve kapalı araştırma grubu halinde yürütüldüğü görülmektedir.

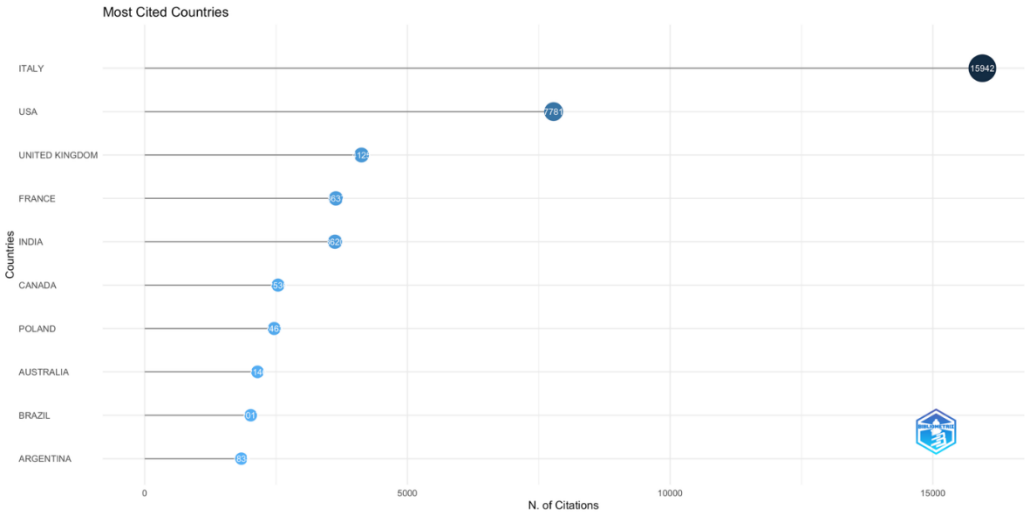


Şekil 6. Sorumlu yazarların iş birliği yaptığı yazar ağı

Makarna konusunda en fazla bilimsel yayın üreten ilk 20 kuruluşa ait veriler Tablo 8'de sunulmuştur. Tablodaki veriler incelendiğinde, literatüre en fazla katkı sağlayan kurumun 186 makale ile Milano Üniversitesi (Univ Milan) olduğu görülmektedir. Milano Üniversitesi'ni sırasıyla Foggia Üniversitesi (138 makale), Lublin Yaşam Bilimleri Üniversitesi (118 makale) ve Parma Üniversitesi (84 makale) izlemektedir. Elde edilen bulgular, makarna alanındaki akademik araştırmaların büyük oranda İtalyan üniversiteleri ve araştırma merkezleri bünyesinde yürütüldüğünü ortaya koymaktadır. İlk 20 sırada 13 İtalyan üniversitesinin yer alması, ülkenin alandaki güçlü kurumsal altyapısını ve nitelikli insan kaynağını yansıtmaktadır. Ayrıca Hindistan (Punjab Agr Univ, Cent Food Technol Res Inst), Arjantin (Univ Nacl Cordoba) ve ABD'deki (N Dakota State Univ) ziraat ve gıda odaklı kurumların listede üst sıralarda yer alması, hammadde üretimi ve gıda teknolojileri ekseninde kurumsal ilginin küresel ölçekte dağılım gösterdiğini doğrulamaktadır (Tablo 8, Şekil 7).

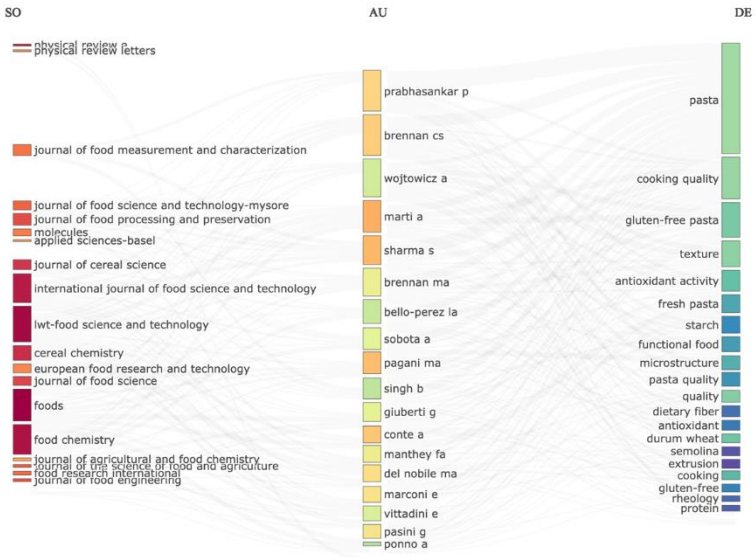
Tablo 8. Konu ile ilgili yayın yapan ilk 20 kuruluş ve makale sayıları

Kuruluş	Makale Sayısı	Kuruluş	Makale Sayısı
Univ Milan	186	Cent Food Technol Res Inst	55
Univ Foggia	138	Univ Bologna	52
Univ Life Sci Lublin	118	Univ Tuscia	51
Univ Parma	84	Univ Palermo	47
Punjab Agr Univ	78	Univ Cattolica Sacro Cuore	46
Univ Padua	73	Univ Florence	46
Univ Bari Aldo Moro	72	N Dakota State Univ	45
Univ Naples Federico Ii	63	Indiana Univ	43
Univ Molise	58	Univ Udine	42
Univ Nacl Cordoba	56	Lincoln Univ	39



Şekil 7. Konu ile ilgili yayın yapan ilk 10 kuruluş ve makale sayıları

Makarna konusunda yayınlanan makalelerin aldıkları toplam atıf sayılarına göre ülkelerin sıralaması Şekil 8'de verilmiştir. Grafikten elde edilen bulgular doğrultusunda, İtalya'nın 15.942 atıf sayısı ile literatürdeki akademik etki liderliğini açık ara sürdürdüğü görülmektedir. İtalya'yı 7.781 atıf ile ABD, 4.125 atıf ile Birleşik Krallık ve 3.563 atıf ile Fransa izlemiştir.



Ülkelerin toplam atıf sayıları değerlendirildiğinde, yayın hacminde olduğu gibi bilimsel etki (citation impact) boyutunda da İtalya ve ABD'nin domine edici bir role sahip olduğu anlaşılmaktadır. Bu iki ülkenin elde ettiği yüksek atıf oranları, bünyelerinde barındırdıkları araştırmacıların ve kurumların

makarna teknolojisi, gıda kimyası ile besinsel kalite üzerine yürüttükleri çalışmaların literatürde temel referans kaynakları olarak kabul gördüğünü göstermektedir.

Şekil 8. En çok atıf alan ülkeler sıralaması

Makalede dergiler (SO), yazarlar (AU) ve yazar anahtar kelimeleri (DE) arasındaki ilişkileri ve etkileşim akışını gösteren üç alanlı diyagram (Three-Fields Plot) verileri de incelenmiştir. Elde edilen bulgular doğrultusunda, makarna konusundaki çalışmaların temel olarak LWT-Food Science and Technology, International Journal of Food Science and Technology, Food Chemistry, Foods, Journal of Cereal Science ve Cereal Chemistry gibi gıda bilimi ve tahıl teknolojisi odaklı saygın dergilerde yoğunlaştığı görülmektedir. Prabhasankar P, Brennan CS, Wojtowicz A, Marti A ve Sharma S gibi alanda en üretken yazarların bu dergilerde sıklıkla yayın yaptığı ve çalışmalarını şekillendirdiği anlaşılmaktadır.
Yazarların çalıştıkları ana temalar (DE) ise ağırlıklı olarak pişme kalitesi (cooking quality), glutensiz makarna (gluten-free pasta), tekstürel özellikler (texture), antioksidan aktivite (antioxidant activity) ve fonksiyonel gıda (functional food) olarak tespit edilmiştir (Şekil 9).

Şekil 9. Dergi, yazar ve anahtar kelimeler seçilerek oluşturulan grafik

SONUÇ

Bu çalışmada, son elli yılda makarna alanında gerçekleştirilen bilimsel araştırmalar bibliyometrik bir yaklaşımla incelenmiştir. Elde edilen bulgular, akademik ilginin özellikle son yıllarda belirgin bir ivme kazandığını ve alanın istikrarlı biçimde büyüyen multidisipliner bir yapıya sahip olduğunu göstermektedir. Araştırma odağının geleneksel pişme kalitesi ve tekstürel parametrelerden; glutensiz formülasyonlar, fonksiyonel gıdalar, besinsel zenginleştirme ve yenilikçi proses teknolojilerine doğru evrildiği tespit edilmiştir. Küresel ölçekte İtalya ve ABD gibi ülkeler hem yayın hacmi hem de atıf etkisi açısından liderliği elinde tutarken, bilimsel üretimin ağırlıklı olarak gıda bilimi ve tahıl teknolojisi odaklı dergilerde yoğunlaştığı belirlenmiştir. Elde edilen sonuçlar doğrultusunda, Türkiye gibi üretimde dünyada söz sahibi olan ülkelerin uluslararası ortaklı projeler ve çok merkezli yayın ağlarına entegrasyonu güçlendirilmelidir. Ayrıca tarladan sofraya uzanan değer zincirinde agronomik, biyoteknolojik ve tüketici odaklı araştırmalar bir bütün olarak ele alınmalı; sağlıklı beslenmeye uygun olarak glisemik indeksi düşük, yüksek lifli ve sürdürülebilir hammadde kaynaklarıyla zenginleştirilmiş ürün geliştirme çalışmalarına öncelik verilmelidir.

Öz
1919 Versay Antlaşması ile Polonya devletinin yeniden kurulması ve Doğu Prusya'yı Weimar Almanyası'ndan ayıran Danzig Koridoru'nun yaratılması, Alman devlet aklında telafisi imkânsız bir travma doğurmuştur. Bu travma, geleneksel Prusya askeri ekolü ile Adolf Hitler'in nasyonal sosyalist ideolojisi arasında Polonya karşıtı tarihsel bir mutabakat inşa etmiştir. Alman askeri ve bürokratik elitleri Batı'daki ezeli rakiplerine karşı klasik bir askeri saygı ve profesyonel rekabet beslerken Polonya'yı toprak gasp eden yapay bir devlet olarak görmüş ve ona karşı ırksal-mekânsal bir hınç biriktirmiştir. Hitler açısından ise Polonya, Kavgam kitabında formüle edilen Lebensraum (Hayat Sahası) doktrininin ilk ve kaçınılmaz tasfiye hedefidir. 1933-1939 yılları arasında Hitler ve Alman askeri karar alıcılarının Polonya'ya bakışındaki ideolojik süreklilik ve askeri elitin rövanşizmi kronolojik bir düzlemde üç ana aşamada somutlaşmıştır. İlk olarak Hitler'in iktidara geldikten sonra Polonya ile imzaladığı 1934 Saldırmazlık Paktı, yayılmacı hedeflerden vazgeçiş değil; Batı cephesinde elini güçlendirene ve yeniden silahlanma programını tamamlayana kadar Doğu'da zaman kazanma stratejisidir. İkinci aşamada, Münih Konferansı sonrasında Çekoslovakya'nın parçalanmasıyla birlikte baskı artmış; Danzig'in iadesi ve eksterritoryal bir ulaşım koridoru talebi masaya konmuştur. Üçüncü ve nihai aşamada ise, Polonya'nın İngiltere ve Fransa'dan güvenlik garantisi alarak bu talepleri reddetmesiyle kâğıt üzerindeki manevralar bitmiş ve Kavgam'daki asıl imha konsepti devreye sokulmuştur. Danzig Krizi, sadece konjonktürel bir sınır anlaşmazlığı değil, Versay düzenini yıkarak Doğu Avrupa'yı Almanlaştırmak isteyen Prusya intikamcılığı ile Nazi yayılmacılığının ortak patlama noktası olmuştur. Sonuç olarak bu çalışma, İkinci Dünya Savaşı'nın çıkış nedenlerini sadece taktiksel krizler üzerinden değil, Alman devlet aklındaki tarihsel ve ideolojik Polonya karşıtlığı üzerinden yeniden okumayı amaçlamaktadır.

Abstract
The reconstitution of the Polish state by the 1919 Treaty of Versailles and the creation of the Danzig Corridor, which severed East Prussia from Weimar Germany, inflicted an irreparable trauma on the German state mind. This trauma forged an anti-Polish historical consensus between the traditional Prussian military school and Adolf Hitler's National Socialist ideology. While the German military and bureaucratic elites harbored a classic military respect and professional rivalry toward their arch-rivals in the West, they viewed Poland as an artificial state usurping their territory and accumulated a racial-spatial resentment against it. For Hitler, Poland was the first and inevitable target of liquidation under the doctrine of *Lebensraum* (Living Space) formulated in his book *Mein Kampf*. Between 1933 and 1939, the ideological continuity in the perspective of Hitler and German military decision-makers toward Poland, combined with the revanchism of the military elite, materialized chronologically in three main phases. First, the 1934 Non-Aggression Pact signed with Poland after Hitler came to power was not a renunciation of expansionist goals, but a strategy to buy time in the East until Germany could strengthen its hand on the Western front and complete its rearmament program. In the second phase, following the Munich Conference and the partition of Czechoslovakia, pressure mounted; the return of Danzig and the demand for an extraterritorial transport corridor were put on the table. In the third and final phase, as Poland rejected these demands by securing security guarantees from Britain and France, the maneuvers on paper came to an end and the actual concept of annihilation in *Mein Kampf* was set in motion. The Danzig Crisis was not merely a conjectural border dispute, but the joint eruption point of Prussian revanchism and Nazi expansionism, both seeking to overthrow the Versailles order and Germanize Eastern Europe. Consequently, this study aims to re-read the causes of the outbreak of the

Second World War not merely through tactical crises, but through the historical and ideological anti-Polish sentiment within the German state mind.

THE EPISTEMIC NEAR-MISS AND GOTHIC INTUITION IN FEMALE KNOWLEDGE IN "CHRISTABEL" AND NORTHANGER ABBEY

"CHRISTABEL" VE NORTHANGER ABBEY ESERLERİNDE KADIN BİLGİSİNDE GOTİK SEZGİ VE EPİSTEMİK KIL PAYI YANILGI

Asst. Prof. Tülay DAĞOĞLU AKTEMUR
Independent Researcher, English Language and Literature

Abstract
This study examines the relationship between Samuel Taylor Coleridge's poem "Christabel" (1816) and Jane Austen's novel *Northanger Abbey* (1817) through their contemporaneous investigations of the epistemic vulnerabilities of women and the conditions under which women's perceptions of danger are made valid or made invalid. Both "Christabel" and *Northanger Abbey* are studied together because both rely on Gothic elements of secrecy, ambiguity, threat, uncertain evidence, and interpretation to create a crisis of knowledge. In each text, the Gothic becomes a space wherein the woman's intuition is tested against the patriarchal voice and modes of rational thinking. In light of Miranda Fricker's concepts of testimonial and hermeneutical injustice, as well as Kristie Dotson's theory of epistemic silencing, the study argues that Coleridge and Austen use Gothic intuition to show two different forms in which women have been marginalized in their epistemology: Christabel's knowledge is silenced, while Catherine Morland's knowledge is corrected because its interpretation is factually incorrect but perceptive. Christabel possesses both experiential and bodily knowledge of the threat posed by Geraldine, but gradually finds herself unable to transform such knowledge into credible evidence. Hence, her story demonstrates epistemic silencing because she possesses knowledge that is never made part of the credibility economy. On the other hand, while Catherine is aware that General Tilney represents an embodiment of patriarchy's menace, her identification of him as such occurs through the conventions of the Gothic, turning her valid perception into a false story about criminality. This study describes Catherine's condition as an example of "epistemic near-miss," which involves a kind of knowledge where the literal interpretation is mistaken, but the actual perception of danger is accurate. Reading both texts together reveals that Gothic intuition is neither irrational nor exaggerated, but may serve as another mode of understanding patriarchal power. Therefore, female epistemic vulnerability results not only from the limitations in knowledge but from structural arrangements that govern whose perceptions are speakable, believable, and socially meaningful.
Keywords: Epistemic silencing, testimonial and hermeneutical injustice, Gothic intuition, *Christabel*, *Northanger Abbey*

Özet
Bu çalışma, Samuel Taylor Coleridge'in "Christabel" (1816) adlı şiiri ile Jane Austen'ın *Northanger Abbey* (1817) adlı romanı arasındaki ilişkiyi, kadınların epistemik kırılganlıklarına ve kadınların tehlikeye ilişkin algılarının hangi koşullar altında geçerli sayıldığı ya da geçersiz kılındığına yönelik dönemdaş incelemeleri üzerinden ele almaktadır. "Christabel" ve *Northanger Abbey*, gizlilik, belirsizlik, tehdit, kesinlikten yoksun kanıt ve yorumlama gibi Gotik unsurlardan yararlanarak bir bilgi krizini sahnelemeleri nedeniyle birlikte ele alınmaktadır. Her iki eserde de Gotik, kadın sezgisinin ataerkil otorite ve toplumsal olarak kabul gören akılcı düşünme biçimleri karşısında sınandığı bir alan işlevi görür. Miranda Fricker'ın "tanıklık adaletsizliği ve yorumsal adaletsizlik" kavramları ile Kristie Dotson'ın "epistemik susturma" kuramından hareket eden bu çalışma, Coleridge ve Austen'ın Gotik sezgiyi kadınların epistemik açıdan ötekileştirilmesinin iki farklı biçimini ortaya koymak için kullandıklarını ileri sürmektedir: Christabel'in bilgisi susturulurken, Catherine Morland'ın bilgisi, yorumu olgusal açıdan yanlış fakat algısal açıdan isabetli olduğu için disipline edilip düzeltilmektedir. Christabel, Geraldine'in oluşturduğu tehdide ilişkin hem deneyimsel hem de bedensel bilgiye sahiptir; ancak bu bilgiyi giderek güvenilir bir tanıklığa dönüştüremez hâle gelir. Dolayısıyla onun deneyimi, bilginin mevcut olmasına rağmen güvenilirlik ekonomisine dâhil edilemediği epistemik susturma olgusunun bir örneğini oluşturur. Catherine ise General Tilney'nin ataerkil bir tehdit oluşturduğunu doğru biçimde sezer; ancak bu sezgiyi Gotik anlatının kalıpları aracılığıyla yorumlayarak geçerli bir güç algısını olgusal açıdan yanlış bir suç anlatısına dönüştürür. Bu çalışma Catherine'in durumunu "epistemik kıl payı yanılgı" olarak tanımlamaktadır: olgusal yorumun yanlış olduğu, ancak altta yatan

tehlike algısının isabetli kaldığı bir bilme biçimi. İki metnin birlikte okunması, Gotik sezginin yalnızca irrasyonel ya da abartılı olmadığını, aksine ataerkil iktidarı kavramanın alternatif bir yolu olarak işlev görebileceğini göstermektedir. Dolayısıyla kadınların epistemik kırılganlığı yalnızca bilgisizlikten kaynaklanmaz; aynı zamanda kimin algısının dile getirilebilir, inanılır ve toplumsal açıdan anlamlı kabul edileceğini belirleyen yapısal düzenlemeler tarafından da üretilir.

Anahtar Kelimeler: Epistemik susturma, tanıklık ve yorumsal adaletsizlik, Gotik sezgi, "Christabel," *Northanger Abbey*

HIGH-HEELED OR FLAT? EXAMINING WOMEN MANAGERS' FOOTWEAR CHOICES IN THE CONTEXT OF AUTHORITY, POWER, AND PROFESSIONAL IDENTITY

TOPUKLU MU, TOPUKSUZ MU? KADIN YÖNETİCİLERİN AYAKKABI TERCİHLERİNİN OTORİTE, GÜÇ VE PROFESYONEL KİMLİK BAĞLAMINDA İNCELENMESİ

Abstract
This study aims to examine women managers' perceptions of the high-heeled or flat footwear they prefer in the workplace and the meanings they attribute to these choices within the dimensions of authority, power, and professional identity. A qualitative research approach was adopted, and semi-structured interviews were used as the data collection method. The study group consisted of nine middle- and senior-level women managers working in different sectors in Karaman, Türkiye. Participants were selected based on the criterion of having managerial experience in line with the purpose of the study, using purposive sampling. The interviews addressed participants' footwear preferences in the workplace, the factors influencing these preferences, and changes in their footwear choices under different working conditions; the meanings attributed to these choices were evaluated in the context of authority, power, and professional identity. The data were analyzed using descriptive and content analysis methods. The findings indicate that women managers' footwear preferences are not limited to aesthetic considerations and physical comfort. While participants who preferred high-heeled footwear associated this choice with authority, power, self-confidence, professionalism, and a managerial appearance, those who preferred flat footwear defined managerial authority independently of footwear, in terms of knowledge, experience, character, and behavior. The findings also indicate that working conditions, physical comfort, freedom of movement, and the level of formality of the setting are important determinants of footwear preferences. In this respect, the study demonstrates that women managers' footwear choices carry multidimensional meanings related to appearance and self-perception, shaped by managerial experience and working conditions, and contributes to understanding footwear choice as an element that acquires meaning within these contexts.

Keywords: Women Managers, High-heeled Footwear, Footwear Choice, Authority, Power, Professional Identity

Öz
Bu araştırmanın amacı, kadın yöneticilerin iş yaşamında tercih ettikleri yüksek topuklu veya topuksuz ayakkabılara ilişkin algılarını ve bu tercihlere yükledikleri anlamları otorite, güç ve profesyonel kimlik boyutları çerçevesinde incelemektir. Araştırmada nitel araştırma yaklaşımı benimsenmiş ve veri toplama yöntemi olarak yarı yapılandırılmış görüşme tercih edilmiştir. Araştırmanın çalışma grubunu, Karaman ilinde farklı sektörlerde görev yapan 9 orta ve üst düzey kadın yönetici oluşturmaktadır. Katılımcıların belirlenmesinde, araştırmanın amacı doğrultusunda yöneticilik deneyimine sahip olma ölçütü esas alınmış olup amaçlı örnekleme yöntemi kullanılmıştır. Görüşmelerde katılımcıların iş yaşamındaki ayakkabı tercihleri, tercihlerini etkileyen unsurlar ve farklı çalışma koşullarında ayakkabı tercihlerindeki değişimler ele alınmış; bu tercihlere yükledikleri anlamlar otorite, güç ve profesyonel kimlik bağlamında değerlendirilmiştir. Elde edilen veriler, betimsel analiz ve içerik analizi yöntemleriyle çözümlenmiştir. Bulgular, kadın yöneticilerin ayakkabı tercihlerinin yalnızca estetik ve fiziksel rahatlıkla sınırlı olmadığını; yüksek topuklu ayakkabı tercih eden katılımcıların bu tercihi otorite, güç, özgüven, profesyonellik ve yönetici görünümüyle ilişkilendirirken, topuksuz ayakkabı tercih edenlerin yöneticilik otoritesini ayakkabıdan bağımsız olarak bilgi, deneyim, karakter ve davranış üzerinden tanımladığını göstermektedir. Ayrıca çalışma koşulları, fiziksel rahatlık, hareket özgürlüğü ve bulunulan ortamın resmiyet düzeyinin ayakkabı tercihlerinde belirleyici olduğu görülmektedir. Bu yönüyle araştırma, kadın yöneticilerin ayakkabı tercihlerinin yöneticilik deneyimi ve çalışma koşullarıyla şekillenen,

görünüm ve benlik algısına ilişkin çok boyutlu anlamlar taşıdığını ortaya koymakta ve ayakkabı tercihinin bu bağlamlarda anlam kazanan bir unsur olarak değerlendirilmesine katkı sağlamaktadır.

ABSTRACT
With the increasing adoption of electronic documents, the volume of data generated in accounting processes has expanded substantially. Consequently, the reliability of accounting records depends not only on technical data entry but also on whether the content of an electronic document is semantically and accounting-wise consistent with the transaction recorded. This study proposes an explainable artificial intelligence architecture for detecting semantic and accounting inconsistencies in Turkish electronic documents, particularly e-Invoices and similar e-documents. The proposed system combines natural language processing of document descriptions with structured accounting variables, including transaction amounts, VAT rates, document dates, account codes, debit-credit relationships, document types, and accounting periods. Turkish document text will first be transformed into contextual semantic representations through an NLP-based approach. These representations will then be integrated with rule-based accounting controls and a machine learning-based risk model to generate a risk score for each prospective accounting record. Rather than producing only a binary decision such as “appropriate” or “suspicious,” the system is designed to provide an evidence-based explanation indicating which textual and accounting characteristics contributed to the detected risk. The research will adopt a design science methodology and evaluate the prototype using synthetic and anonymized accounting records. Model performance will be assessed through precision, recall, F1-score, ROC-AUC/PR-AUC, explanation accuracy, and expert evaluation time. Comparative experiments will examine rule-based, structural-feature-only, NLP-only, and hybrid approaches. The expected contribution is a Turkish accounting-domain-oriented, explainable, human-in-the-loop quality-control architecture that can identify potential inconsistencies before records are finalized. The study aims to extend accounting automation beyond account-code recommendation toward proactive error prevention, risk prioritization, and accountable human–AI collaboration.

ÖZET
Elektronik belge kullanımının giderek yaygınlaşmasıyla birlikte muhasebe süreçlerinde üretilen veri hacmi önemli ölçüde artmıştır. Buna bağlı olarak muhasebe kayıtlarının güvenilirliği yalnızca teknik veri girişine değil, elektronik belge içeriğinin oluşturulan işlemle anlamsal ve muhasebesel açıdan tutarlı olmasına da bağlı hâle gelmiştir. Bu çalışmada, özellikle e-Fatura ve benzeri elektronik belgelerdeki semantik ve muhasebesel tutarsızlıkların tespit edilmesine yönelik açıklanabilir yapay zekâ tabanlı bir mimari önerilmektedir. Önerilen sistem; belge açıklamalarının doğal dil işleme yöntemleriyle analiz edilmesini, işlem tutarları, KDV oranları, belge tarihleri, hesap kodları, borç-alacak ilişkileri, belge türleri ve muhasebe dönemleri gibi yapısal muhasebe değişkenleriyle birlikte değerlendirilmesini kapsamaktadır. Türkçe belge metinleri ilk olarak NLP tabanlı bir yaklaşımla bağlamsal anlamsal temsillere dönüştürülecektir. Daha sonra bu temsiller, kural tabanlı muhasebe kontrolleri ve makine öğrenmesi tabanlı bir risk modeli ile bütünleştirilerek her bir muhasebe kaydı için risk skoru

üretilecektir. Sistem, yalnızca "uygun" veya "şüpheli" şeklinde ikili bir karar vermek yerine, tespit edilen riskin hangi metinsel ve muhasebesel özelliklerden kaynaklandığını kanıta dayalı olarak açıklayacak şekilde tasarlanmıştır. Araştırmada tasarım bilimi metodolojisi benimsenerek prototip sistem sentetik ve anonimleştirilmiş muhasebe kayıtları kullanılarak değerlendirilecektir. Model performansı precision, recall, F1-score, ROC-AUC/PR-AUC, açıklama doğruluğu ve uzman değerlendirme süresi ölçütleri üzerinden incelenecektir. Karşılaştırmalı deneylerde kural tabanlı, yalnızca yapısal özelliklere dayalı, yalnızca NLP tabanlı ve hibrit yaklaşımlar değerlendirilecektir. Çalışmanın beklenen katkısı, Türkçe muhasebe alanına özgü, açıklanabilir ve insan-döngüde (human-in-the-loop) çalışan bir kalite kontrol mimarisinin geliştirilmesidir. Bu mimarinin, muhasebe kayıtları kesinleştirilmeden önce olası tutarsızlıkları belirlemesi ve muhasebe otomasyonunu hesap kodu önerisinin ötesine taşıyarak proaktif hata önleme, risk önceliklendirme ve hesap verebilir insan–yapay zekâ iş birliğine katkı sağlaması amaçlanmaktadır.

ANAHTAR KELİMELER: Yapay zekâ; doğal dil işleme; muhasebe bilgi sistemleri; e-belge; açıklanabilir yapay zekâ; anomali tespiti; semantik tutarlılık; muhasebe otomasyonu.

MULTILINGUAL SPEECH EMOTION RECOGNITION: AN XLS-R-BASED APPROACH COMBINING TURKISH, POLISH, AND URDU CORPORA

Abstract
This study addresses speech emotion recognition (SER) in a multilingual setting by combining three emotional speech corpora from three different languages Turkish (TurEV-DB), Polish (nEMO), and Urdu (URDU-Dataset) within a common emotion label space. Because the corpora label emotions with different strings and differ substantially in utterance duration and recording conditions, a careful harmonization and preprocessing pipeline is applied. Emotion labels are mapped to a common canonical space, and only the three classes consistently represented across all three corpora (angry, happy, sad) are retained. All recordings are resampled to 16 kHz, converted to mono, and segmented into fixed one-second windows, and low-energy segments are discarded. Each corpus–emotion cell is then downsampled to an equal number of examples, producing a set balanced with respect to both class and language (2,115 segments). To obtain realistic performance estimates, a stratified, group-based split (StratifiedGroupKFold) keeps all segments derived from the same original recording on the same side of the split, thereby preventing data leakage. The multilingually pretrained wav2vec2-XLS-R-300M model is fine-tuned with its convolutional feature encoder frozen. On the balanced test set, the model attains an overall accuracy of 90.9% and a macro-F1 score of 0.909. The results indicate that multilingually pretrained speech representations can be fine-tuned into high-performing emotion classifiers even with limited and heterogeneous multilingual data, provided that label harmonization, corpus and class balancing, and leakage-safe splitting are handled explicitly.
Keywords: Speech emotion recognition, multilingual learning, transfer learning, wav2vec2, XLS-R.

1. Introduction

Speech emotion recognition (SER) aims to automatically infer a speaker's affective state from acoustic signals, and it has become increasingly relevant for applications such as human–computer interaction, call-center analytics, healthcare, and dialogue personalization (El Ayadi et al., 2011; Akçay & Oğuz, 2020). Much of the emotional information in speech is carried by prosodic and spectral characteristics pitch, energy, rhythm, and voice quality which can, in principle, transcend the lexical content and even the language being spoken. This language-independent dimension of vocal emotion is precisely what makes multilingual and cross-lingual SER a plausible undertaking, yet it also exposes systems to confounds that arise when data are aggregated across languages and recording conditions.

In recent years, self-supervised speech representation models have substantially advanced the field. Models such as wav2vec 2.0 learn general-purpose speech representations from large amounts of unlabeled audio and can subsequently be fine-tuned for downstream tasks with comparatively little labeled data (Baevski et al., 2020). This paradigm is particularly attractive for SER, where labeled emotional corpora are typically small: features extracted from pretrained wav2vec 2.0 models have been shown to outperform traditional hand-crafted descriptors even with shallow downstream classifiers (Pepino et al., 2021), and transfer learning from self-supervised backbones has repeatedly proven effective under low-resource conditions (Nasersharif & Azad, 2023; Jafarzadeh et al., 2024). The multilingual successor of wav2vec 2.0, XLS-R, is pretrained on data spanning 128 languages and yields

representations that transfer well across languages (Babu et al., 2022), making it a natural backbone for multilingual speech tasks.

Despite this progress, most SER research remains concentrated on a small number of high-resource languages, and datasets for many languages are scarce (Akçay & Oğuz, 2020). Recent efforts have begun to close this gap by releasing emotional speech corpora for under-resourced languages, including Turkish (Canpolat et al., 2020), Polish (Christop, 2024), and Urdu (Latif et al., 2018; Zaheer et al., 2023). However, these corpora were created independently: they adopt different emotion label sets and naming conventions, vary in utterance structure (isolated words, full sentences, or spontaneous excerpts), and were recorded under different conditions (acted vs. spontaneous). A well-documented consequence is that SER systems trained and evaluated within a single corpus degrade sharply when transferred to unseen corpora or languages (Latif et al., 2023), and that models readily overfit to corpus-specific artifacts rather than learning genuinely emotion-bearing cues (Parry et al., 2019; Zhang et al., 2019). Naively pooling heterogeneous corpora can therefore allow a model to exploit corpus- or language-specific shortcuts, and can inflate reported performance when evaluation is not designed to prevent it cross-corpus validation typically yields substantially lower, and more realistic, estimates than same-corpus validation (Talpur et al., 2025).

The work most closely related to the present study applies multilingual self-supervised backbones to emotion recognition across languages. XLS-R has been used directly as an end-to-end multilingual SER model (Das & Haque, 2025), and large speech models from the wav2vec 2.0 and Whisper families have been systematically compared as cross-lingual feature extractors across many languages (D'Asaro et al., 2024). What remains comparatively underexplored is the joint combination of three typologically and acoustically dissimilar under-resourced languages Turkish, Polish, and Urdu within a single, explicitly harmonized label space, together with an evaluation protocol that guards against the specific confounds introduced by such heterogeneity.

This study investigates whether a multilingually pretrained model can be fine-tuned into a robust emotion classifier when three such heterogeneous corpora are combined. The main contributions are as follows: (i) a harmonization and preprocessing pipeline that unifies emotion labels, standardizes sampling rate and duration through fixed one-second windowing, and balances the data with respect to both class and language; (ii) a leakage-safe, group-based evaluation protocol that prevents segments originating from the same recording from appearing in both the training and test sets; and (iii) an empirical evaluation of a fine-tuned XLS-R model, reported both overall and per corpus, together with an explicit discussion of the distinction between in-domain and genuine cross-lingual performance.

2. Literature Review

Self-supervised representations and transfer learning for SER

The dominant trend in contemporary SER is the reuse of self-supervised speech representation learning (S3RL) models wav2vec 2.0, HuBERT, and WavLM as feature extractors or fine-tuning backbones (Baevski et al., 2020; Babu et al., 2022). Because emotional corpora are small, transferring knowledge from models pretrained on large unlabeled speech collections mitigates data scarcity. Pepino et al. (2021) showed that combining representations from multiple internal layers of a pretrained wav2vec 2.0 model, fed to shallow classifiers, surpasses systems based on spectrograms or earlier wav2vec features. Jafarzadeh et al. (2024) compared Wav2Vec2 and HuBERT as automatic feature extractors across several benchmark corpora, confirming the robustness of S3RL features relative to hand-crafted descriptors. Because the massive parameter counts of these backbones complicate fine-tuning for low-resource SER, Nasersharif and Azad (2023) proposed a compact model that transfers the HuBERT convolutional encoder and replaces its transformer stack with a lightweight conformer block, attaining performance comparable to full S3RL models. Fine-tuning strategy has itself been a subject of study: Gao et al. (2023) introduced a two-stage fine-tuning scheme that first adapts wav2vec 2.0 with automatic speech recognition and gender pretraining before emotion fine-tuning, alleviating gradient conflicts and improving downstream accuracy. Beyond the wav2vec family, WavLM-derived domain emotion embeddings have been applied to both single- and cross-lingual SER (Yang et al., 2024), and D'Asaro et al. (2024) benchmarked English-only and multilingual large speech models including XLS-R and Whisper as cross-lingual feature extractors, reporting that the optimal representation layer and the benefit of multilingual pretraining depend on both the backbone family and the target language. These

findings collectively motivate the use of a multilingually pretrained backbone, with a frozen convolutional encoder, as adopted in the present study.

Cross-corpus and cross-lingual generalization

A recurring finding across the literature is that SER systems generalize poorly beyond the corpus on which they were trained. Parry et al. (2019) analyzed several deep architectures under cross-corpus training with six corpora and observed that recurrent models tend to overfit the specific corpora present in training, whereas convolutional models generalize better to an unseen corpus evidence that aggregated training data can encourage the learning of corpus identity rather than emotion. Zhang et al. (2019) framed corpus, domain (spoken vs. sung), and speaker gender as explicit sources of variability and used multi-task learning to model them jointly, finding that cross-corpus performance generally improves as more training corpora are added. In genuinely cross-lingual settings, Latif et al. (2023) demonstrated that both cross-corpus and cross-language transfer suffer from large domain gaps and proposed a self-supervised adversarial dual-discriminator network to learn domain-invariant, emotionally discriminative representations without target labels.

Multilingual and cross-lingual evaluations have since expanded to more diverse language sets, including Amharic against several other languages (Retta et al., 2023) and combinations of Urdu, English, German, and Italian using hybrid deep and transformer-based models (Almadhor et al., 2026). To address the twin obstacles of distribution shift and scarce target-language labels, Agarla et al. (2024) proposed a semi-supervised transformer-based method that leverages a small number of labeled target-language examples, while Lu et al. (2026a) combined multi-wavelet data augmentation with contrastive feature decoupling to isolate language-invariant emotion representations. These studies establish cross-lingual generalization as the central open problem that motivates careful, leakage-aware experimental design.

Domain adaptation and domain generalization

A substantial body of work reduces the source–target discrepancy through explicit domain adaptation or domain generalization. Gao et al. (2022) applied domain-adversarial training together with center loss to suppress non-affective information and tighten intra-class feature distributions, improving both cross-corpus and multi-corpus evaluation. This line was extended by an adversarial domain-generalized transformer that fuses supervised and pretrained features via a gated mechanism to learn a shared source–target distribution (Gao et al., 2024). Feature-transformation approaches include the triplet-network preprocessing of Lee (2021), which learns corpus-invariant emotional features and reports large cross-corpus gains across English and Japanese corpora, and the generalized subspace distribution adaptation framework of Li et al. (2023), which learns a shared low-dimensional subspace and a divergence-reducing distance metric between corpora. Domain adaptation has also been directed at the speaker as a nuisance factor: Lu et al. (2026b) recast speaker-independent SER as multi-source domain adaptation, using joint distribution adaptation and a dynamic balance factor to handle unseen-speaker distributions. Although the present study does not employ adversarial adaptation, this literature underscores why speaker- and corpus-level variability must be controlled, and it frames the leave-one-language-out protocol proposed here as future work as the natural test of genuine domain generalization.

Under-resourced languages and emotional speech corpora

Progress in multilingual SER depends on the availability of emotional corpora for languages beyond English, German, and Italian. For Turkish, TurEV-DB provides word-level utterances in four emotional categories, produced by amateur actors and denoised after recording (Canpolat et al., 2020). For Polish, the nEMO corpus offers sentence-level simulated emotional speech recorded by professional actors (Christop, 2024). For Urdu, two complementary resources exist: the URDU dataset of spontaneous emotional excerpts drawn from television talk shows (Latif et al., 2018), and the larger scripted SEMOUR+ repository of emotion-tagged speech from native speakers (Zaheer et al., 2023). The heterogeneity across these corpora word- versus sentence- versus discourse-level units, and acted versus spontaneous elicitation is precisely the source of variability that complicates their combination. Talpur et al. (2025) made this concrete for Urdu by validating SER models across three Urdu corpora and showing that same-corpus evaluation can overestimate unweighted average recall by up to roughly thirteen percentage points relative to cross-corpus evaluation, reinforcing the need for realistic, cross-corpus-aware protocols.

Data balancing, evaluation, and leakage

Finally, a smaller but important strand of work emphasizes that dataset construction and evaluation design materially affect reported results. Corpus and class imbalance can bias models toward majority sources, and unprincipled data partitioning can allow near-duplicate material to appear on both sides of a split. Bano et al. (2026) addressed this directly when constructing a balanced multimodal emotion benchmark, curating a class-balanced subset and enforcing strict movie- and series-level splits to prevent content overlap between partitions and thereby enable more reliable generalization estimates. Together with the cross-corpus overestimation reported by Talpur et al. (2025) and the corpus-overfitting behavior documented by Parry et al. (2019), these observations motivate the methodological emphasis of the present study: simultaneous balancing of language and class, uniform windowing to neutralize utterance-duration cues, and group-based, leakage-safe splitting that keeps all segments of a given recording on a single side of the partition.

Positioned against this literature, the present study combines three under-resourced languages that have not, to our knowledge, been jointly modeled within a unified label space, and it foregrounds the harmonization, balancing, and leakage-prevention steps that much prior work treats only implicitly.

3. Methodology

The overall experimental pipeline, spanning source corpora, data preparation, and evaluation, is summarized in Figure 1. It is organized into three stages: preprocessing, in which emotion labels are harmonized and the audio is standardized and segmented; dataset preparation, in which the segmented data are balanced across classes and languages and then partitioned in a leakage-safe manner; and modeling and evaluation, in which a multilingually pretrained backbone is fine-tuned and assessed. Each stage is described in the following subsections.

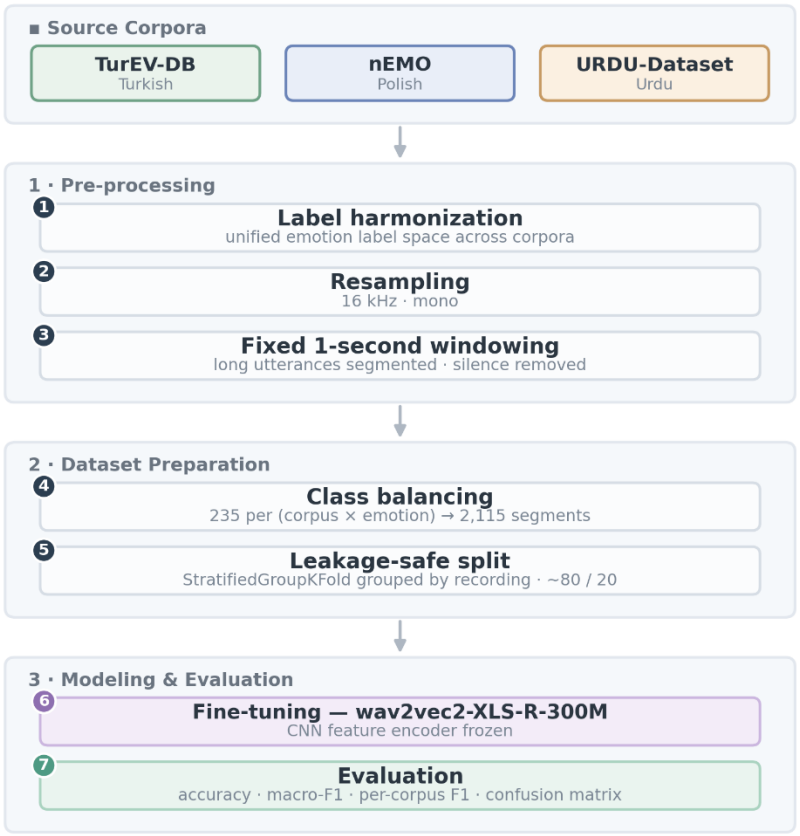

Figure 1. Overview of the proposed multilingual SER pipeline.

Datasets

Three publicly available emotional speech corpora, each representing a different language and recording condition, were combined for this study. TurEV-DB (Canpolat et al., 2020) is a Turkish corpus of short, word-level utterances produced by amateur actors and denoised after recording. nEMO (Christop, 2024)

is a Polish corpus of sentence-level, simulated emotional speech recorded by nine professional actors; although it originally provides six emotion categories, only those shared across all three corpora were retained. URDU-Dataset (Latif et al., 2018) consists of spontaneous emotional speech excerpts drawn from television talk shows and, in contrast to the other two corpora, captures naturally occurring rather than acted emotion. Taken together, these corpora constitute a deliberately heterogeneous benchmark that varies simultaneously in language, elicitation method, and utterance structure.

Label harmonization

Because the corpora annotate emotions using different surface strings (for example, *anger* versus *angry*), the same underlying emotion would otherwise be treated as several distinct classes, encouraging the model to learn the source corpus rather than the emotional content. To avoid this, all annotations were mapped onto a common canonical label space (anger/angry → *angry*; happiness/happy → *happy*; sadness/sad → *sad*). The neutral category was deliberately excluded, as it was represented inconsistently across corpora: the Turkish corpus provides a "calm" category rather than genuinely neutral speech, which would render a merged neutral class internally incoherent. Consequently, the study was restricted to the three emotions consistently present in all three corpora, namely *angry*, *happy*, and *sad*.

Audio preprocessing and segmentation

The three corpora differ substantially in utterance length. As shown in Figure 2, the Turkish utterances are word-level and short (median ≈ 0.95 s), whereas the Polish and Urdu recordings are sentence-level or spontaneous and considerably longer (medians of ≈ 2.4 s and ≈ 2.0 s, respectively), with maximum durations exceeding five seconds. If left unaddressed, such systematic differences would allow utterance duration, and by extension corpus identity, to act as a spurious proxy for emotion. To neutralize this confound, all recordings were resampled to 16 kHz and converted to mono, and then divided into non-overlapping, fixed one-second windows. Recordings longer than one second yielded multiple segments, providing an implicit form of data augmentation, whereas residual segments shorter than one second were zero-padded to the target length. Segments whose root-mean-square (RMS) energy fell below a fixed threshold, and which therefore consisted predominantly of silence, were discarded.

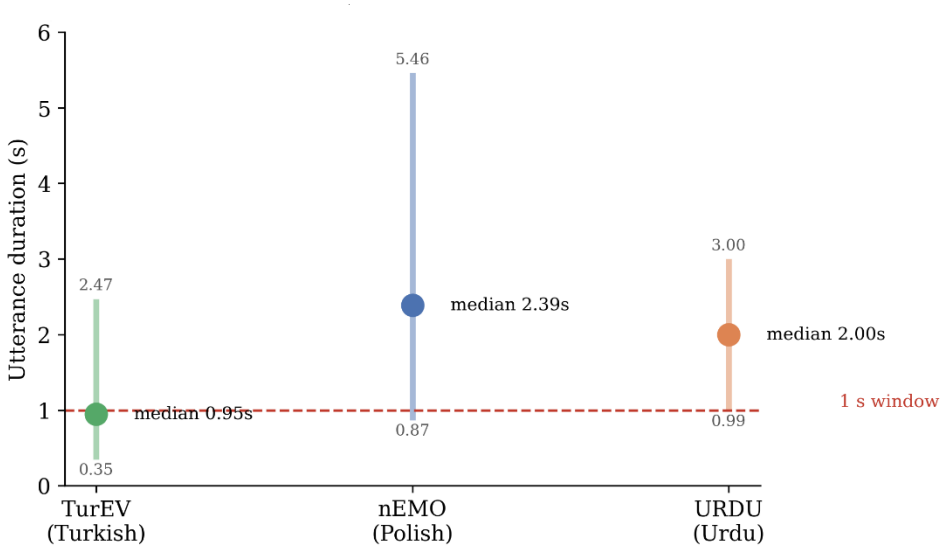

Figure 2. Utterance duration by corpus (median with min–max range).

Corpus and class balancing

Fixed-length segmentation introduced a pronounced imbalance: because the sentence-level Polish corpus produces more segments per recording, it dominated the resulting pool. To eliminate this bias, each (corpus × emotion) cell was randomly downsampled to an equal number of examples, namely 235 segments per cell. This single operation balances the data with respect to class and language simultaneously, yielding a final set of 3 emotions × 3 languages × 235 = 2,115 segments. The effect of this step is illustrated in Figure 3, which contrasts the class–language distribution before and after balancing.

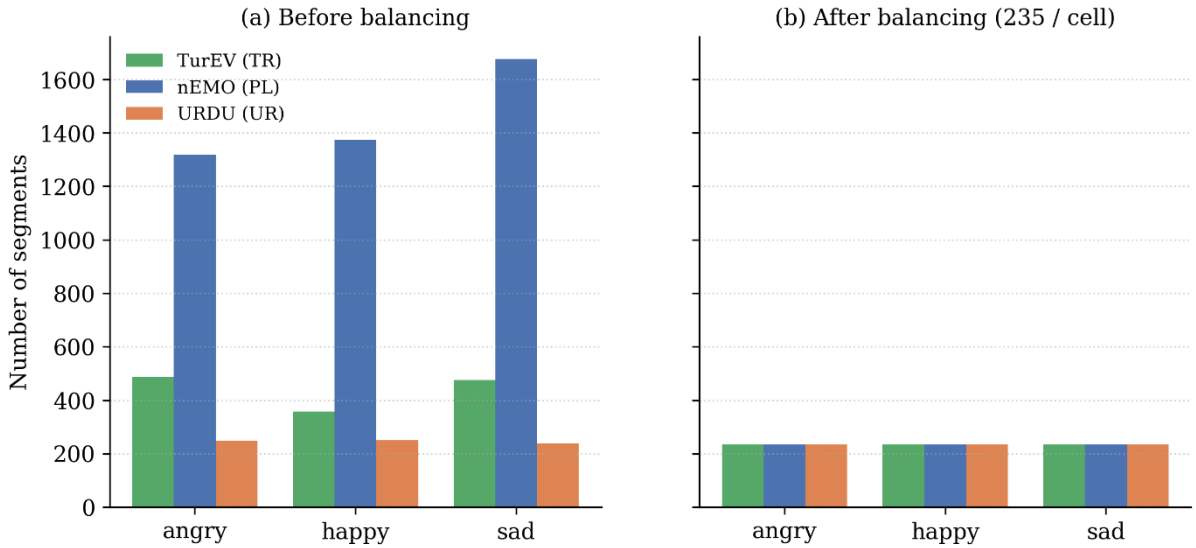

Figure 3. Class–language distribution before and after balancing.

Leakage-safe partitioning

Segmenting long recordings inevitably produces several segments that originate from the same source recording and therefore share the same speaker and acoustic environment. Allocating such segments to both the training and test sets would expose the model to test examples that closely resemble training examples, thereby inflating the reported performance through data leakage. To prevent this, partitioning was performed at the level of the original recording, so that all segments derived from a given recording were assigned exclusively to one side of the split. A stratified, group-based scheme (StratifiedGroupKFold) was used to preserve class balance while enforcing this grouping constraint, and the absence of any recording shared between the two sets was verified programmatically. An approximate 80% / 20% train–test ratio was targeted.

Model architecture and fine-tuning

The classification backbone was wav2vec2-XLS-R-300M (Babu et al., 2022), whose large-scale multilingual pretraining spans all three study languages. During fine-tuning, the convolutional feature encoder was kept frozen while the transformer layers and the classification head were updated, a standard and stabilizing practice for wav2vec2-family models. Optimization used a batch size of 4 with a gradient accumulation factor of 2 (yielding an effective batch size of 8), a learning rate of 1×10^{-5}, a warm-up ratio of 0.1, and 10 training epochs. Gradient checkpointing was enabled to reduce memory consumption, and bf16 mixed-precision training was employed for numerical stability. The final model was selected as the checkpoint achieving the highest validation macro-F1.

Evaluation protocol

As the evaluation set is balanced across classes, performance is summarized primarily through overall accuracy and macro-averaged F1, complemented by per-class precision, recall, and F1 and by a confusion matrix. To characterize the model's multilingual behavior, test performance is additionally disaggregated by corpus. Finally, as a preliminary point of comparison, a four-class configuration that additionally included the neutral category was trained using a smaller, English-pretrained backbone (wav2vec 2.0 base; Baevski et al., 2020).

4. Results and Discussion

The proposed configuration (XLS-R-300M, three classes) achieved an overall accuracy of 90.9% and a macro-F1 of 0.909 on the test set. Per-class results are reported in Table 1.

Table 1. Per-class performance (XLS-R-300M, three classes).

Class	Precision	Recall	F1	Support
Angry	0.912	0.918	0.915	146
Happy	0.908	0.838	0.872	142

Class	Precision	Recall	F1	Support
Sad	0.908	0.977	0.941	131
Macro avg.	0.909	0.911	0.909	419

Across the three classes, the highest performance was obtained for the *sad* class (F1 = 0.941) and the lowest for the *happy* class (F1 = 0.872). The confusion matrix in Figure 4 indicates that most errors originate from the *happy* class, with some happy segments misclassified as *angry* and others as *sad*. This pattern is consistent with happiness spanning both high-arousal instances, which acoustically resemble anger, and low-arousal ones. In contrast, sad segments were almost never confused with angry ones, as expected given the pronounced difference in arousal between these two emotions.

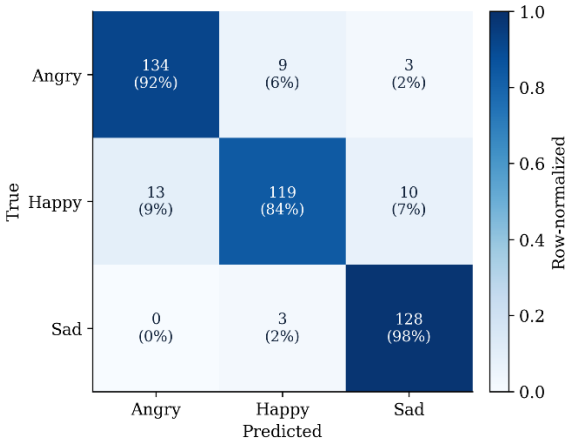

Figure 4. Row-normalized confusion matrix on the test set.

Table 2 reports macro-F1 disaggregated by corpus. An important methodological caveat must be emphasized: these scores correspond to a model in which all three languages are present in the training set, and therefore reflect in-domain performance rather than genuine cross-lingual transfer.

Table 2. Per-corpus macro-F1 (in-domain)

Corpus (Language)	Macro-F1	Support
nEMO (Polish)	0.927	141
URDU (Urdu)	0.949	137
TurEV (Turkish)	0.849	141

A notable observation is that the Turkish corpus yields the lowest performance despite being represented in training. A plausible explanation is that TurEV-DB comprises word-level utterances that are, in terms of duration, the shortest in the study (median ≈ 0.95 s); shorter segments carry less prosodic context than sentence-level or spontaneous excerpts, making emotion discrimination comparatively harder. This suggests that, in multilingual setups combining corpora with different utterance structures, performance depends not only on language but also on recording condition and utterance structure.

For comparison, a preliminary four-class configuration (wav2vec 2.0 base, including neutral) yielded a macro-F1 of 0.882. In that setting, the low precision of the neutral class (0.763), together with the confusion matrix, indicated that the model routed ambiguous examples into neutral, effectively turning it into a catch-all class; removing neutral eliminated this behavior. It should be noted, however, that the difference between the two configurations is confounded by two simultaneous changes — the backbone model and the number of classes — and thus cannot be attributed to a single factor.

Overall, these results indicate that a multilingually pretrained backbone can be fine-tuned into a strong three-class emotion classifier across Turkish, Polish, and Urdu, provided that label harmonization, corpus and class balancing, and leakage-safe evaluation are handled explicitly. At the same time, the per-corpus breakdown makes clear that the reported figures characterize in-domain behavior, and that utterance structure remains an influential factor alongside language.

5. Conclusion

This study combined emotional speech corpora from three languages (Turkish, Polish, and Urdu) within a common label space and fine-tuned a multilingually pretrained model (XLS-R-300M) to distinguish

three basic emotions (*angry*, *happy*, *sad*). The macro-F1 of 0.909 on a balanced test set demonstrates that multilingual pretrained representations can achieve strong emotion recognition performance even with limited and heterogeneous data.

Beyond the reported accuracy, the principal contribution of this work is methodological: it explicitly addresses pitfalls that are frequently overlooked in multilingual SER, namely cross-corpus label harmonization, the elimination of utterance-duration differences through uniform windowing, the simultaneous balancing of corpus and class, and — most importantly — the prevention of segment-level data leakage through group-based splitting. Each of these steps is essential for results that are realistic and reproducible.

Several limitations should be acknowledged. The per-corpus results reflect in-domain rather than cross-lingual transfer performance; the balanced set is relatively small (2,115 segments); classification is performed at the one-second segment level without utterance-level aggregation; and the corpora mix acted and spontaneous recordings, leaving recording-condition heterogeneity as a residual source of variability.

As future work, the most natural extension is a leave-one-language-out protocol — training on two languages and testing on the third — to quantify genuine cross-lingual transfer. Utterance-level aggregation, data-augmentation techniques, and a broader emotion set are further directions for improving both performance and generalizability.

Abstract
The rapid advancement of generative models, particularly Generative Adversarial Networks and diffusion models, has made it possible to synthesize human faces that are visually indistinguishable from real photographs, raising serious concerns about misinformation, impersonation, and the erosion of trust in visual media. Reliable automated detection of such synthetic faces has therefore become an urgent research problem, and convolutional neural networks combined with transfer learning have emerged as the dominant approach. However, the many available CNN architectures are usually studied in isolation and under differing datasets and protocols, making it difficult to determine which backbone is most suitable when both accuracy and computational efficiency matter. This paper presents a controlled comparative study of five widely used ImageNet-pretrained architectures ResNet-18, ResNet-50, DenseNet-121, MobileNetV2, and EfficientNet-B0 for binary real/fake face classification on the public RVF10K dataset, whose real faces come from the Flickr-Faces-HQ dataset and whose fake faces are generated by StyleGAN. All models are trained and evaluated under an identical pipeline, including a freeze-then-fine-tune transfer-learning schedule, shared data augmentation, the Adam optimizer, and early stopping, and are assessed using accuracy, precision, recall, F1-score, and ROC–AUC together with efficiency indicators (parameter count and training time). Experimental results show that every model exceeds 97% accuracy with ROC–AUC above 0.997; ResNet-50 achieves the highest accuracy (99.53%) but is by far the largest model, whereas EfficientNet-B0 and MobileNetV2 attain nearly identical accuracy at a small fraction of the parameters and training cost. Notably, model size is found to be a poor predictor of detection accuracy, underscoring that architectural design is more decisive than raw capacity for practical GAN-generated face detection.

Özet
Üretici modellerin, özellikle Üretici Çekişmeli Ağların (Generative Adversarial Networks, GAN) ve difüzyon modellerinin hızla gelişmesi, gerçek fotoğraflardan görsel olarak ayırt edilemeyen sentetik insan yüzlerinin üretilmesini mümkün hâle getirmiştir. Bu durum, yanlış bilgilendirme, kimliğe bürünme ve görsel medyaya duyulan güvenin zedelenmesi gibi ciddi endişeleri beraberinde getirmektedir. Bu nedenle, söz konusu sentetik yüzlerin güvenilir ve otomatik bir şekilde tespit edilmesi acil bir araştırma problemi hâline gelmiş; transfer öğrenme ile birlikte kullanılan evrişimsel sinir ağları (CNN) ise bu alandaki baskın yaklaşımlardan biri olmuştur.
Bununla birlikte, mevcut çok sayıdaki CNN mimarisi genellikle birbirinden bağımsız olarak ve farklı veri kümeleri ile deneysel protokoller altında incelenmektedir. Bu durum, hem doğruluğun hem de hesaplama verimliliğinin önemli olduğu senaryolarda hangi omurga mimarisinin en uygun olduğunu belirlemeyi zorlaştırmaktadır. Bu çalışma, kamuya açık RVF10K veri kümesi üzerinde ikili gerçek/sahte yüz sınıflandırması gerçekleştirmek amacıyla, ImageNet üzerinde önceden eğitilmiş ve yaygın olarak kullanılan beş mimariyi — ResNet-18, ResNet-50, DenseNet-121, MobileNetV2 ve EfficientNet-B0 —

kontrollü bir karşılaştırmalı çalışma kapsamında incelemektedir. Veri kümesindeki gerçek yüzler Flickr-Faces-HQ veri kümesinden, sahte yüzler ise StyleGAN kullanılarak oluşturulmuştur.
Tüm modeller, karşılaştırmanın adil olmasını sağlamak amacıyla aynı deneysel işlem hattı kullanılarak eğitilmiş ve değerlendirilmiştir. Bu kapsamda, dondurma ve ardından ince ayar (fine-tuning) aşamalarından oluşan bir transfer öğrenme stratejisi, ortak veri artırma işlemleri, Adam optimizasyon algoritması ve erken durdurma (early stopping) uygulanmıştır. Modeller; doğruluk (accuracy), kesinlik (precision), duyarlılık (recall), F1-skoru ve ROC–AUC metriklerinin yanı sıra parametre sayısı ve eğitim süresi gibi verimlilik göstergeleri kullanılarak değerlendirilmiştir.
Deneysel sonuçlar, tüm modellerin %97'nin üzerinde doğruluk ve 0,997'nin üzerinde ROC–AUC değerine ulaştığını göstermektedir. ResNet-50, %99,53 doğruluk ile en yüksek başarıyı elde etmiş, ancak açık ara en büyük model olmuştur. Buna karşılık, EfficientNet-B0 ve MobileNetV2, çok daha az sayıda parametre ve daha düşük eğitim maliyetiyle ResNet-50'ye neredeyse eşdeğer doğruluk seviyelerine ulaşmıştır. Özellikle, model boyutunun tespit doğruluğunun zayıf bir belirleyicisi olduğu görülmüştür. Bu bulgu, pratik GAN tarafından üretilen yüz tespitinde başarının yalnızca modelin ham kapasitesine değil, mimari tasarımın daha belirleyici olduğuna işaret etmektedir.

Abstract
The way in which the natural, historical, and cultural values of destinations are communicated to visitors plays a crucial role in transforming these resources into meaningful tourism experiences. Contemporary destination branding encompasses not only the promotion of tourist attractions but also the communication of a destination's distinctive identity, local culture, and narratives of the past. This study aims to examine the contribution of storytelling to destination branding by exploring the historical, natural, and cultural values of Ermenek, a district of Karaman, Türkiye. A qualitative research approach was adopted, and semi-structured interviews were conducted with twelve participants. The collected data were analyzed using thematic analysis.
The findings indicate that Ermenek's destination identity is shaped by a diverse range of elements, including the history of the Karamanoğulları, natural landscapes, the Ermenek Dam Lake, Zeyve Bazaar, Yörük culture, local gastronomic values, and the district's distinctive microclimatic characteristics. Participants emphasized that attractions such as Ayhatun Cave, canyons, the old bazaar, historical structures, and local culinary products should receive greater attention in tourism promotion. The interviews also revealed various local narratives concerning the legend of the Karaman sheep, the Karamanoğulları and Ottoman periods, Ayhatun Cave, Karamanoğlu Mehmet Bey, historical sites, hospitality, and gift-giving traditions. All twelve participants stated that these stories are not sufficiently incorporated into existing tourism promotional activities. They noted that current promotional efforts rely predominantly on visual content, while the historical and cultural narratives associated with places remain largely underrepresented. Furthermore, some local narratives are at risk of disappearing from collective memory due to their limited documentation in written sources.Overall, the findings demonstrate that Ermenek possesses substantial storytelling potential; however, this potential has not yet been transformed into a comprehensive destination brand narrative. The use of local stories through short videos, social media, reenactments, thematic routes, and digital applications is therefore recommended.

Özet
Destinasyonların sahip olduğu doğal, tarihî ve kültürel değerlerin turizm açısından anlam kazanmasında bu değerlerin ziyaretçilere nasıl aktarıldığı önemli bir rol oynamaktadır. Günümüzde destinasyon markalaşması yalnızca turistik çekiciliklerin tanıtılmasını değil destinasyonun özgün kimliğinin, yerel kültürünün ve geçmişine ilişkin anlatıların ziyaretçilere aktarılmasını da kapsamaktadır. Bu çalışmanın amacı Karaman'ın Ermenek ilçesinin sahip olduğu tarihî, doğal ve kültürel değerlerin hikâyeleştirme yoluyla destinasyon markalaşmasına katkısını ortaya koymaktır. Araştırmada nitel araştırma yöntemi benimsenmiş ve on iki katılımcıyla yarı yapılandırılmış görüşmeler gerçekleştirilmiştir. Elde edilen veriler tematik analiz yöntemiyle değerlendirilmiştir. Bulgular Ermenek'in destinasyon kimliğinin Karamanoğulları tarihi, doğal güzellikleri, baraj gölü, Zeyve Pazarı, Yörük kültürü, gastronomik değerleri ve mikroklimatik özellikleri gibi çok sayıda unsurdan oluştuğunu göstermektedir. Katılımcılar ayrıca Ayhatun Mağarası, kanyonlar, eski çarşı, tarihî yapılar ve yerel gastronomik değerlerin daha fazla öne çıkarılması gerektiğini belirtmiştir. Görüşmelerde Karaman'ın koyunu efsanesi, Karamanoğulları ve Osmanlı dönemine ilişkin anlatılar, Ay hatun Mağarası, Karamanoğlu Mehmet Bey, tarihî mekânlar,

misafirperverlik ve hediyeleşme gelenekleri gibi çeşitli yerel hikâyeler ortaya çıkmıştır. On iki katılımcının tamamı bu hikâyelerin mevcut Ermenek turizm tanıtımlarında yeterince kullanılmadığını ifade etmiştir. Katılımcılar tanıtımların ağırlıklı olarak görsel unsurlara dayandığını ve mekânların arkasındaki tarihî ve kültürel anlatıların yeterince aktarılmadığını vurgulamıştır. Ayrıca bazı yerel anlatıların yazılı kaynaklara yeterince aktarılmaması nedeniyle yöre halkının hafızasında kaybolma riski taşıdığı belirtilmiştir. Sonuç olarak Ermenek'in güçlü bir hikâyeleştirme potansiyeline sahip olduğu, ancak bu potansiyelin bütüncül bir destinasyon marka anlatısına yeterince dönüştürülemediği belirlenmiştir. Hikâyelerin kısa videolar, sosyal medya, canlandırmalar, tematik rotalar ve dijital uygulamalar aracılığıyla kullanılması önerilmektedir.

Abstract
Digital addiction, characterized by loss of control, compulsive engagement, and functional impairment associated with smartphone and social media use, has become an increasing focus of psychological research. This study proposed and tested a multidimensional higher-order conceptualization of digital addiction encompassing five behavioral dimensions: phone attachment, digital interference, compulsive scrolling, fear of missing out (FoMO), and social media overuse. A cross-sectional survey was conducted with 494 Turkish participants (58.2% female; M age = 25.56, SD = 11.22, range = 14–61). Exploratory and confirmatory factor analyses supported a five-factor structure loading onto a single higher-order construct, with excellent model fit. Digital addiction was positively associated with psychological distress, including depression, anxiety, anger, sleep disturbance, obsessive-compulsive symptoms, dissociation, impulsivity, and borderline personality features, and negatively associated with psychological resources, including self-esteem, purpose in life, and religiosity. Regression analyses indicated that distress variables explained roughly twice as much variance in digital addiction (32.1%) as psychological resources did (16.8%), with depression emerging as the strongest unique correlate.

Everyday smartphone behaviors, specifically carrying the phone in hand rather than in a pocket or bag, and placing it on the dining table during meals, were associated with higher digital addiction and poorer psychological functioning, supporting their potential use as observable behavioral markers. Approximately 10% of participants displayed serious digital addiction. These findings support conceptualizing digital addiction as a coherent, multidimensional construct embedded within a broader network of psychological distress, resources, and everyday behavioral patterns, with implications for assessment and preventive intervention.
Keywords: digital addiction; smartphone use; social media; psychological distress

Özet

Akıllı telefon ve sosyal medya kullanımına bağlı kontrol kaybı, kompulsif kullanım ve işlevsellikte bozulma ile karakterize edilen dijital bağımlılık, psikoloji araştırmalarında giderek daha fazla ilgi gören bir konu hâline gelmiştir. Bu çalışmada dijital bağımlılığın; telefona bağlılık, dijital aksama, kompulsif kaydırma, gelişmeleri kaçırma korkusu (FoMO) ve aşırı sosyal medya kullanımı olmak üzere beş davranışsal boyutu kapsayan çok boyutlu ve üst düzey bir yapı olarak kavramsallaştırılması önerilmiş ve sınanmıştır. Kesitsel araştırma, 494 Türk katılımcıyla (%58,2 kadın; yaş Ort. = 25,56, SS = 11,22, aralık = 14–61) gerçekleştirilmiştir. Açımlayıcı ve doğrulayıcı faktör analizleri, tek bir üst düzey yapıya yüklenen beş faktörlü modeli desteklemiş ve modelin mükemmel uyum gösterdiğini ortaya koymuştur. Dijital bağımlılık; depresyon, kaygı, öfke, uyku bozukluğu, obsesif-kompulsif belirtiler, dissosiyasyon, dürtüsellik ve borderline kişilik özelliklerini içeren psikolojik sıkıntı göstergeleriyle pozitif; benlik saygısı, yaşam amacı ve dindarlığı içeren psikolojik kaynaklarla ise negatif yönde ilişkili bulunmuştur. Regresyon analizleri, psikolojik sıkıntı değişkenlerinin dijital bağımlılıktaki varyansın %32,1'ini açıklarken psikolojik kaynakların %16,8'ini açıkladığını; dolayısıyla sıkıntı değişkenlerinin yaklaşık iki kat daha fazla açıklayıcı güce sahip olduğunu göstermiştir. Depresyon, dijital bağımlılıkla en güçlü özgün ilişkiye sahip değişken olarak öne çıkmıştır. Gündelik akıllı telefon kullanım davranışlarından özellikle telefonu cepte veya çantada taşımak yerine elde taşımak ve yemek sırasında telefonu masanın üzerine koymak, daha yüksek dijital bağımlılık ve daha olumsuz psikolojik işlevsellikle ilişkili bulunmuştur. Bu bulgular, söz konusu davranışların gözlenebilir davranışsal göstergeler olarak kullanılabileceğine işaret etmektedir. Katılımcıların yaklaşık %10'unda ciddi düzeyde dijital bağımlılık gözlenmiştir. Bu bulgular, dijital bağımlılığın psikolojik sıkıntılar, psikolojik kaynaklar ve gündelik davranış örüntülerinden oluşan daha geniş bir ağ içinde yer alan bütünlüklü ve çok boyutlu bir yapı olarak kavramsallaştırılmasını desteklemekte; ayrıca değerlendirme ve önleyici müdahaleler açısından önemli çıkarımlar sunmaktadır.
Anahtar Kelimeler: dijital bağımlılık; akıllı telefon kullanımı; sosyal medya; psikolojik stres

BIOGENIC NANOPARTICLES FOR MANAGING PLANT DNA VIRUSES AND THEIR INSECT VECTORS

Abstract
Plant DNA viruses, particularly begomoviruses and badnaviruses, remain difficult to manage because systemic infection is established rapidly and many economically important species depend on efficient insect transmission. Biogenic nanoparticles offer a complementary strategy in which nanoscale materials are produced or functionalized using plants, microorganisms, or bio-derived polymers rather than exclusively chemical routes. Their potential extends beyond direct antiviral activity to induction of host defenses, protection and delivery of nucleic-acid-based antivirals, sensitive virus detection, and suppression of insect vectors. This review synthesizes recent evidence from 2022-2026 on biogenic nanoparticles for management of plant DNA viruses and their vectors. Current evidence is strongest for green-synthesized silver nanoparticles and related nanoformulations against whiteflies, whereas direct studies on DNA viruses are fewer. Chitosan nanoparticles have shown notable activity against banana streak virus, and nano-enabled delivery and diagnostic platforms provide additional routes for managing begomovirus diseases. Despite this promise, translation to field use requires reproducible particle characterization, transmission-focused efficacy trials, crop and non-target safety assessment, environmental fate studies, and clear regulatory standards. An integrated strategy combining vector suppression, host defense priming, sequence-specific antiviral delivery, and early diagnosis is likely to be the most realistic pathway for deployment.
Keywords: biogenic nanoparticles; plant DNA viruses; begomoviruses; banana streak virus; whitefly; Bemisia tabaci; nanophytovirology.

1. Introduction

Plant DNA viruses are disproportionately important in tropical and subtropical agriculture because many are efficiently transmitted by phloem-feeding insects and can establish persistent epidemics in high-value crops. Begomoviruses in the family Geminiviridae are single-stranded DNA viruses transmitted mainly by members of the *Bemisia tabaci* whitefly complex, and their rapidly evolving plant-vector-virus interactions complicate durable control (Naveed et al., 2023; Morin et al., 2024; Biswas and Mandal, 2025). DNA pararetroviruses such as banana streak virus (BSV) add a different management problem because infection may be associated with persistent planting material and complex host responses. Conventional management therefore relies on resistant cultivars, clean planting material, sanitation, insecticides, and vector exclusion, yet these measures can be undermined by resistance-breaking virus variants, insecticide resistance, reinvasion by mobile vectors, and incomplete availability of host resistance.

Nanotechnology is increasingly examined as an additional layer of plant-virus management. Recent reviews describe nanoparticles as antiviral agents, defense elicitors, diagnostic components, and carriers for RNA interference or other sequence-specific molecules (Dutta et al., 2022; Singh et al., 2022; Warghane et al., 2024; Rajeshkumar et al., 2025; Vasquez-Gutierrez et al., 2025). The biogenic approach

is particularly attractive because nanoparticles can be synthesized with plant extracts, fungi, bacteria, or biologically derived macromolecules, potentially reducing dependence on harsh reducing and capping reagents. However, "green" or "biogenic" should not be treated as synonymous with harmless; biological activity and environmental behavior still depend on particle composition, size, coating, concentration, dissolution, and exposure route.

A central challenge is that the evidence base is uneven. Broad nanoparticle-plant virus research is expanding, but direct experiments targeting DNA plant viruses remain relatively scarce compared with studies of RNA viruses or fungal and bacterial pathogens. At the same time, strong progress has been made in nano-enabled diagnostics and insect-vector suppression, creating an opportunity to intervene before or during transmission rather than only after systemic infection is established (Mishra et al., 2025; Kalu et al., 2026). Accordingly, this review focuses on the recent 2022-2026 literature and evaluates biogenic nanoparticles through four linked functions: direct antiviral action, stimulation or delivery of host antiviral responses, suppression of insect vectors, and integration into practical disease-management systems.

2. Biogenic Nanoparticle Platforms and Antiviral Mechanisms

Biogenic nanoparticles encompass inorganic particles produced using biological reducing and stabilizing systems as well as bio-derived nanocarriers such as chitosan. Plant-mediated synthesis commonly exploits polyphenols, flavonoids, sugars, proteins, and other metabolites that reduce metal ions and simultaneously cap the resulting particles; microbial synthesis uses extracellular or intracellular metabolites from bacteria and fungi for related purposes (Nguyen et al., 2022; Omran and Baek, 2022; Nguyen et al., 2023). Silver nanoparticles (AgNPs) remain the most studied green nanomaterial in crop protection, but ZnO, Cu/CuO, MgO, iron oxides, gold, and hybrid nanocomposites are also being developed. Bio-derived polymers provide another route because their surfaces can be functionalized, loaded with nucleic acids or active compounds, and formulated for foliar delivery (Wasule et al., 2024). Recent reviews focused specifically on bacterial- and fungal-mediated routes further demonstrate how microbial metabolism can support eco-friendly nanoparticle synthesis and phytopathogen management (Ali et al., 2024; Aasim et al., 2025).

Several mechanisms are relevant to plant-virus management. First, nanoparticles may directly interact with viral particles, capsid proteins, or nucleic acids, potentially reducing stability, replication, movement, or successful establishment of infection. Metal-based particles can also generate reactive oxygen species or release ions, although the same chemistry that damages pathogens can become phytotoxic at excessive exposure (Warghane et al., 2024). Second, nanoparticles may prime plant immunity by altering redox signaling, antioxidant systems, defense enzymes, and salicylic acid-, jasmonic acid-, or ethylene-associated pathways. Such priming is attractive for viruses because the target is the host response rather than a single viral enzyme, but its magnitude is highly dependent on dose, crop species, particle characteristics, and application timing (Saied et al., 2026; Parihar et al., 2026). Third, nanocarriers can protect unstable antiviral cargo. Double-stranded RNA, small RNAs, peptides, or other bioactive molecules are readily degraded on leaf surfaces or in the environment; nanoscale carriers can improve adhesion, persistence, cellular uptake, and controlled release. This concept is particularly relevant to DNA viruses because sequence-specific RNA silencing can target viral transcripts even though the viral genome itself is DNA (Rajeshkumar et al., 2025). Fourth, nanoparticle-enabled sensing can increase the sensitivity or portability of virus detection, supporting earlier roguing and vector management before visible symptoms become widespread. A recent plant-virus-focused synthesis similarly identifies nanocarrier-mediated RNA delivery as a central route for overcoming dsRNA instability and uptake limitations, while emphasizing formulation-to-field validation as the critical translational gap (Ali, 2026).

Biogenic synthesis adds sustainability advantages, but reproducibility remains a technical bottleneck. Extract composition varies with species, tissue, season, extraction conditions, and metabolite profile, which can change particle size and surface chemistry between batches. For this reason, recent assessments emphasize full characterization of size distribution, morphology, zeta potential, coating chemistry, release behavior, and stability rather than labeling a preparation simply as "green" (Salam et al., 2026; Kalu et al., 2026). Mechanistic interpretation therefore requires linking biological outcomes to well-defined physicochemical properties.

3. Applications Against Plant DNA Viruses

The direct evidence for biogenic nanoparticles against plant DNA viruses is promising but still narrow. The clearest recent example is BSV, a DNA pararetrovirus of banana. Abdelbaset et al. (2024) reported that foliar chitosan nanoparticles substantially reduced BSV colonization and disease development. Under their experimental conditions, a 200 mg L−1 pre-inoculation treatment reduced disease incidence by 75% and disease severity by 95.3%, while higher pre- and post-inoculation concentrations produced complete suppression of the measured disease-incidence and severity endpoints. These results are important because they demonstrate that a bio-derived nanoparticle can alter the outcome of a DNA-virus infection *in planta* rather than functioning only as an insecticide or diagnostic material.

For begomoviruses, the recent literature is more developed conceptually than experimentally. Reviews of nanophytovirology identify direct nanoparticle-virus interactions, host defense induction, and nano-assisted delivery of RNA-silencing molecules as the principal antiviral routes (Dutta et al., 2022; Singh et al., 2022; Warghane et al., 2024). This framework is especially relevant to tomato yellow leaf curl disease and related begomovirus complexes because viral transcripts, replication-associated proteins, movement functions, or conserved genome regions can be targeted by sequence-specific molecules. Nanocarrier protection may extend persistence of such molecules on leaves and facilitate entry into plant tissues, addressing two major limitations of naked RNA-based sprays (Rajeshkumar et al., 2025; Vasquez-Gutierrez et al., 2025; Mishra et al., 2025). Nevertheless, recent reviews also make clear that robust field-scale demonstrations against DNA viruses are not yet proportional to the number of proposed nano-delivery concepts. Diagnosis is therefore an important complementary application. Devika et al. (2024) demonstrated nano-PCR for early detection of tomato leaf curl virus, illustrating how nanomaterials can enhance diagnostic sensitivity in a DNA-virus pathosystem. Earlier and more sensitive detection does not itself cure an infected plant, but it can materially improve integrated management by enabling rapid removal of inoculum sources, screening of nursery stock, and earlier vector-control decisions. Current nanotechnology reviews similarly position high-sensitivity detection as part of a disease-management continuum rather than a separate laboratory activity (Salam et al., 2026; Kalu et al., 2026).

The most defensible interpretation is therefore that biogenic nanoparticles have demonstrated proof of principle against at least one important plant DNA virus and possess credible mechanisms for broader use, but evidence should not be generalized across all Geminiviridae, Nanoviridae, or Caulimoviridae. Future experiments should quantify viral DNA, transcript abundance, symptom severity, yield, and transmission to recipient plants while comparing prophylactic and post-infection applications. Such designs would distinguish true antiviral activity from temporary symptom mitigation or nonspecific growth promotion.

4. Suppression of Insect Vectors and Virus Transmission

For many plant DNA viruses, vector management is an antiviral intervention because infection risk depends on vector abundance, feeding behavior, acquisition, retention, and inoculation. Begomoviruses are tightly associated with *B. tabaci*, and recent molecular reviews show that successful transmission is shaped by reciprocal interactions among the plant, virus, whitefly, and whitefly-associated factors (Naveed et al., 2023; Morin et al., 2024; Zhao et al., 2025; Biswas and Mandal, 2025). A nanoparticle that reduces vector survival, development, settling, or feeding could therefore decrease primary or secondary spread even without directly contacting the virus.

Biogenic AgNPs provide the strongest recent vector-control evidence. Shahid et al. (2022) evaluated an *Azadirachta indica*-mediated silver nanoformulation against *B. tabaci* and reported substantial biocidal activity, supporting plant-extract-based synthesis as a route to whitefly control. Bhadani et al. (2022) used extracellular metabolites of *Beauveria bassiana* to biosynthesize AgNPs and demonstrated concentration- and exposure-dependent toxicity to whiteflies. These studies are particularly relevant because *B. tabaci* transmits numerous begomoviruses affecting tomato, cotton, cassava, pepper, legumes, and other crops. In a related whitefly system, Trujillo et al. (2025) produced highly stable rosemary-mediated silver nanocomposites and reported approximately 98% average mortality of naturally occurring *Trialeurodes vaporariorum* on greenhouse tomato after 10 days. Although *T. vaporariorum* is not the principal vector of begomoviruses, the result strengthens the broader case for green silver nanomaterials as whitefly-active formulations. The likely insecticidal mechanisms are multifactorial. Recent synthesis of AgNP toxicology describes disruption of membrane permeability,

oxidative stress and reactive oxygen species production, interference with enzymes and proteins, impairment of DNA replication, and developmental abnormalities (Martínez-Cisterna et al., 2024). Biogenic coatings may additionally influence adhesion, uptake, persistence, and compatibility with plant surfaces. However, high vector mortality should not automatically be equated with proportional reduction in virus transmission. Whiteflies can acquire and inoculate virus before death, and sublethal exposure could alter movement or feeding in ways that either decrease or, under some circumstances, redistribute transmission risk.

Accordingly, vector-focused nanoparticle trials should include epidemiological endpoints. Useful measurements include probing behavior, acquisition access period, inoculation efficiency, latent or retention dynamics where relevant, numbers of newly infected plants, and epidemic progress, in addition to LC50 or mortality. Combining nanoparticle-based vector suppression with host defense priming or sequence-specific antiviral cargo could provide two independent barriers to infection, an approach consistent with current nano-enabled plant-virus management frameworks (Mishra et al., 2025). Such combinations may also reduce reliance on repeated conventional insecticide applications if efficacy and selectivity can be demonstrated under field conditions.

5. Field Translation, Biosafety and Research Priorities

The main barrier to adoption is no longer the absence of plausible mechanisms but the lack of standardized evidence linking nanoparticle properties to durable field performance. Biogenic synthesis can reduce hazardous chemical inputs, yet batches generated with crude plant or microbial extracts may differ in size, surface coating, aggregation state, ion release, and biological potency (Omran and Baek, 2022; Nguyen et al., 2023). Minimum characterization should therefore include particle size distribution, morphology, zeta potential, chemical composition, capping molecules, storage stability, and behavior after dilution in realistic spray water. Without these data, efficacy cannot be reliably reproduced across laboratories or seasons (Wasule et al., 2024; Salam et al., 2026).

Safety evaluation must be equally specific. Nanoparticles that generate oxidative stress in vectors or pathogens may also affect crop cells, beneficial arthropods, soil microorganisms, aquatic organisms, or food-chain exposure. Recent assessments emphasize dose-dependent phytotoxicity, uncertainty concerning environmental persistence and transformation, and the need to study nanoparticle-microbiome-plant interactions under field conditions (Kalu et al., 2026; Parihar et al., 2026). Green synthesis may improve the toxicological profile in some cases, but it does not eliminate the need for residue, non-target, and chronic-exposure studies. This is particularly important for AgNPs because both particulate silver and released Ag^+ can contribute to biological effects (Martínez-Cisterna et al., 2024).

Efficacy testing also needs to move from mortality and symptom scores toward transmission-centered field endpoints. The encouraging whitefly control reported for green Ag-based formulations should be validated against virus-vector pairs of direct epidemiological importance, particularly *B. tabaci*-begomovirus systems, using realistic application intervals and environmental conditions (Trujillo et al., 2025). Likewise, the BSV-chitosan nanoparticle result warrants multisite validation, assessment of persistence, and measurement of viral load and yield responses. Nano-enabled delivery systems should be compared with unformulated cargo to demonstrate that the nanoparticle itself provides measurable gains in stability, uptake, dose efficiency, or duration (Vasquez-Gutierrez et al., 2025; Mishra et al., 2025).

A productive research pathway is an integrated “virus-vector-host” design. Candidate formulations should first be characterized physically and chemically, then screened for crop safety, antiviral or vector activity, and host-defense responses. The best candidates should subsequently be tested for reduction of plant-to-plant transmission and yield loss. Diagnostic tools can be integrated to detect low-titer infections and quantify treatment effects. Finally, regulatory development will require agreed definitions for nanoformulations, standardized ecotoxicological protocols, residue and exposure thresholds, and manufacturing quality control. Such steps would allow biogenic nanotechnology to progress from promising laboratory demonstrations to evidence-based components of integrated virus management.

6. Conclusion

Biogenic nanoparticles provide a multifunctional platform for managing plant DNA-virus diseases because they can act on the virus, the host, the vector, or the delivery of antiviral molecules. The strongest current evidence lies in green nanoparticle toxicity against whiteflies and in the demonstrated activity of chitosan nanoparticles against banana streak virus. For begomoviruses and other DNA-virus

groups, nano-enabled defense priming, nucleic-acid delivery, and sensitive diagnostics are scientifically credible but require more direct, transmission-focused validation. Future progress will depend on standardized synthesis and characterization, clear comparisons with non-nano controls, field trials measuring virus spread and yield, and rigorous assessment of crop, environmental, and non-target safety. The most practical role for biogenic nanoparticles is therefore not as a single replacement for existing control measures, but as a component of integrated management that combines early detection, vector suppression, host protection, and targeted antiviral delivery.

Abstract
The rhizosphere microbiome is increasingly recognized as a biologically active shield that protects plants from soil-borne and aboveground pathogens. Rather than acting through a single mechanism, rhizosphere communities restrict pathogen invasion by occupying ecological niches, competing for nutrients, producing antimicrobial metabolites and lytic enzymes, modifying the chemical environment around roots, and priming systemic immune responses. Plants are active participants in this defense system. Root exudates and host genetic traits selectively recruit beneficial microorganisms, particularly after pathogen attack, creating a dynamic "cry-for-help" response that can reinforce disease resistance. Recent work has also moved from descriptive microbiome surveys toward causal approaches using disease-suppressive soils, microbial transplants, synthetic communities, metabolomics, metagenomics, and host-mediated microbiome engineering. This short review synthesizes advances published during 2022-2026, with emphasis on the ecological and molecular mechanisms underlying microbiome-mediated disease suppression, plant-guided recruitment of protective taxa, synthetic microbial communities, and translation to crop protection. Evidence increasingly supports the rhizosphere microbiome as an extension of plant immunity, but field consistency, formulation stability, host specificity, environmental context, and regulatory frameworks remain major barriers to agricultural deployment.
Keywords: rhizosphere microbiome; disease suppression; biological control; root exudates; disease-suppressive soil; synthetic microbial communities; induced systemic resistance

1. Introduction

The rhizosphere is the narrow, metabolically active zone of soil influenced by plant roots, where microbial population densities and biochemical interactions are markedly greater than in bulk soil. Its bacteria, fungi, archaea, protists, and viruses interact with one another and with the host plant, forming a dynamic interface that can determine whether an invading pathogen successfully establishes infection. Contemporary plant pathology therefore increasingly treats the plant and its associated microbiota as an integrated ecological unit rather than viewing immunity as a property of plant cells alone (Santoyo, 2022). Disease-suppressive microbiome research further supports this holobiont-level interpretation (Spooren et al., 2024). Recent syntheses describe the rhizosphere microbiome as an important determinant of disease resistance and a potential first line of defense against soil-borne pathogens (Andargie et al., 2023; Du et al., 2025).

The "biological shield" concept is supported by experiments showing that small differences in microbial community composition can precede major differences in disease outcome. In tomato challenged with Ralstonia solanacearum, rhizosphere community configurations predicted later bacterial wilt outcomes before clear differences in pathogen density were detectable, and several bacteria enriched in healthy plants reduced disease when reintroduced experimentally (Gu et al., 2022). Disease-suppressive soils

provide a broader ecological manifestation of the same phenomenon: susceptible plants can remain relatively healthy in the presence of a virulent pathogen because resident microbial communities restrict pathogen growth or infection (Spooren et al., 2024; Li et al., 2024). The defensive microbiome is not static. It is shaped by soil properties, plant genotype, developmental stage, root chemistry, pathogen pressure, agronomic management, and interactions among microbial kingdoms (Andargie et al., 2023; Liu et al., 2026). Field-oriented assessments in tomato further indicate that manipulation of rhizosphere communities through organic inputs and biological products can contribute to suppression of bacterial, fungal, and nematode diseases, although functional validation in field environments remains less developed than controlled-environment research (Obiazikwor et al., 2025). Recent demonstrations that defined rhizosphere communities can induce systemic resistance to foliar disease also extend the shield beyond the root zone itself (Rigerte et al., 2026). This review examines how the rhizosphere microbiome forms this protective barrier, how plants assemble it, and how microbiome-based disease suppression may be converted into reliable crop-protection technologies.

2. Mechanisms Underlying the Rhizosphere Biological Shield

Microbiome-mediated disease suppression emerges from multiple overlapping mechanisms. The most immediate is colonization resistance: a dense, metabolically active community occupies physical attachment sites and consumes limiting carbon, nitrogen, iron, and micronutrients before an invading pathogen can establish a sufficient population. Such resource competition is strengthened by high community diversity and complementary resource use, making pathogen invasion more difficult than in simplified or disrupted microbiomes (Du et al., 2025; Liu et al., 2026). Longitudinal tomato experiments support this ecological interpretation because healthy plants developed distinct community configurations containing protective taxa before bacterial wilt became visible (Gu et al., 2022).

Antibiosis provides a second protective layer. Rhizosphere bacteria such as *Bacillus*, *Pseudomonas*, and Streptomyces can produce lipopeptides, polyketides, non-ribosomal peptides, antibiotics, siderophores, volatile compounds, and hydrolytic enzymes. Fungi such as Trichoderma contribute mycoparasitism, competition, chitinases, and other antifungal activities. In suppressive soil challenged with *Fusarium solani*, *Bacillus* and *Trichoderma* acted as keystone antagonists; defined consortia containing these taxa markedly reduced pathogen sporulation and root-rot severity (Li et al., 2024). Likewise, maize root exudates recruited *Bacillus amyloliquefaciens* OR2-30, which suppressed Fusarium graminearum partly through lipopeptide production (Xie et al., 2022). Evidence from tomato also supports rhizosphere-associated Pseudomonas: *P. fluorescens* strains reduced Meloidogyne incognita root galling and improved tomato growth under greenhouse conditions (Ayub et al., 2024). A recent review of tomato Fusarium wilt likewise highlights *Pseudomonas*, *Bacillus*, and *Streptomyces* acting through antibiosis, resource competition, growth promotion, and host-defense activation (Tatar et al., 2025). The shield also acts through plant immunity. Beneficial rhizobacteria can prime induced systemic resistance, allowing distal tissues to respond faster or more strongly after pathogen attack without maintaining costly constitutive defense. This process commonly intersects with jasmonic acid, ethylene, salicylic acid, reactive oxygen species, defense enzymes, and transcriptional reprogramming (Du et al., 2025; Spooren et al., 2024). In 2026, defined bacterial SynComs derived from barley and wheat rhizospheres reduced powdery mildew growth on barley leaves while causing only subtle pre-infection transcriptional changes, consistent with immune priming rather than constitutive stress (Rigerte et al., 2026).

Community interactions are equally important. A protective phenotype often cannot be attributed to a single strain because facilitation, metabolite exchange, spatial organization, and cross-kingdom interactions generate emergent functions. Cross-kingdom bacterial-fungal SynComs were more effective than bacteria-only or fungi-only communities in suppressing tomato Fusarium wilt, linking disease control to both microbial interactions and host immune responses (Zhou et al., 2022). A 16-member bacterial community from grafted watermelon similarly protected ungrafted plants against *Fusarium oxysporum*, with *Pseudomonas*-associated functions and microbial synergy contributing to the effect (Qiao et al., 2024). Thus, the biological shield is best understood as a community-level ecological function integrating niche exclusion, antagonism, chemical competition, microbial cooperation, and immune activation rather than as the activity of a single “beneficial microbe” (Andargie et al., 2023).

3. Plant-Guided Recruitment and the Cry-for-Help Response

Plants actively influence rhizosphere assembly through root exudates containing sugars, amino acids, organic acids, phenolics, flavonoids, coumarins, hormones, and other metabolites. These compounds are nutrient sources but also function as selective signals that alter microbial chemotaxis, growth, biofilm formation, and competitive fitness. Consequently, root exudation provides a mechanism by which plants can enrich microorganisms with disease-suppressive traits (Santoyo, 2022; Spooren et al., 2024). The composition of exudates changes with genotype, developmental stage, nutrition, and biotic stress, allowing the host to reshape its microbial environment in response to changing threats (Andargie et al., 2023).

Recent studies provide direct evidence for pathogen-responsive recruitment. Following *Fusarium graminearum* infection, maize altered root exudation in a manner that enhanced recruitment of *B. amyloliquefaciens* OR2-30, which subsequently inhibited the pathogen (Xie et al., 2022). In *Panax notoginseng*, foliar infection modified root exudates and enriched rhizosphere *Trichoderma*, *Bacillus*, and *Streptomyces* while suppressing a soil-borne root-rot pathogen; metabolite amendments reproduced parts of this protective effect (Luo et al., 2022). These findings support the "cry-for-help" model in which pathogen perception in one plant compartment causes chemical changes belowground that recruit protective partners. Host signaling pathways can participate directly in this recruitment. Treatment of tomato with Bacillus cereus AR156 altered salicylic acid- and jasmonic acid/ethylene-related responses, remodeled root exudates, and enriched multiple bacterial genera negatively associated with *Ralstonia* colonization (Yang et al., 2023a). Host genetics can exert a similarly strong effect. The tomato ripening-inhibitor transcription factor influenced root exudate profiles, the abundance of disease-suppressive *Streptomyces*, and resistance to *R. solanacearum*; application of specific exudate compounds restored microbiome suppressiveness in the mutant background (Yang et al., 2023b). This provides a mechanistic link between plant genes, root chemistry, microbiome assembly, and disease phenotype.

Neighboring plants can also modify this defensive recruitment. In tomato-potatoonion intercropping, root-exudate-mediated interactions enhanced recruitment of Bacillus and generated a microbiome suppressive to *Verticillium dahliae*. Taxifolin released in the intercropping context altered tomato root chemistry and indirectly promoted beneficial colonization (Zhou et al., 2023). These results suggest that crop diversity can function as a form of microbiome engineering. More broadly, studies of suppressive soils indicate that repeated pathogen pressure can select plant-associated microbial communities with enhanced protective functions across plant generations or cropping cycles (Spooren et al., 2024; Liu et al., 2026). The rhizosphere shield is therefore jointly constructed by plant genotype, environmental history, neighboring plants, microbial responses, and pathogen-induced signaling.

4. Disease-Suppressive Soils and Synthetic Microbial Communities

Disease-suppressive soils are natural experiments demonstrating that microbial communities can override otherwise favorable conditions for disease. Suppressiveness may arise from broad community activity or from particular functional guilds and can sometimes be transferred to conducive soil through small amounts of suppressive soil, indicating a biological basis (Spooren et al., 2024; Du et al., 2025). Recent network-based studies show that suppressive rhizospheres frequently contain greater numbers of beneficial or antagonistic taxa and more complex interactions than disease-conducive systems. In Fusarium solani-suppressive soil, bacterial and fungal keystone taxa were identified and subsequently validated as antagonists, demonstrating how community profiling can be converted into causal biological control experiments (Li et al., 2024).

Synthetic microbial communities provide a reductionist route for reproducing this protective function. Instead of relying on one inoculant, SynComs combine strains selected for complementary traits such as antagonism, root colonization, biofilm formation, nutrient competition, immune activation, and cross-feeding. A large tomato study constructed bacterial, fungal, and mixed communities from cultured rhizosphere isolates and found that cross-kingdom SynComs provided the strongest suppression of Fusarium wilt, emphasizing functional complementarity (Zhou et al., 2022). In watermelon, a 16-strain core bacterial community derived from grafted plants improved growth and Fusarium resistance in ungrafted plants, and simplified combinations retained protective effects through synergistic interactions (Qiao et al., 2024). Importantly, community composition can contain predictive information before disease becomes obvious. In tomato, minor early differences in rhizosphere assembly forecast later bacterial wilt outcome, suggesting that disease management could eventually move from symptom-

based intervention toward microbiome-based risk diagnosis (Gu et al., 2022). Similar reasoning underlies current attempts to identify core taxa, keystone species, functional genes, and network properties associated with suppressiveness rather than relying solely on taxonomic abundance (Andargie et al., 2023; Liu et al., 2026).

Rhizosphere protection is also capable of extending aboveground. Barley inoculated with defined rhizosphere SynComs showed reduced powdery mildew development even though the pathogen infects leaves, demonstrating that a belowground community can generate systemic protection without requiring direct antagonism at the infection site (Rigerte et al., 2026). Field evidence remains more limited, but analyses of tomato production systems indicate that bio-organic fertilizers, composts, and other biological products can shift resident microbiomes in directions associated with reduced soil-borne disease pressure (Obiazikwor et al., 2025). Together, suppressive soils and SynCom studies show a progression from observation to design: identify protective community states, isolate the organisms or functions responsible, reconstruct them in controlled consortia, and then test whether the resulting shield remains stable in realistic soil and crop environments.

5. Translating the Rhizosphere Shield into Crop Protection

The practical objective is not simply to describe healthy microbiomes but to steer rhizosphere communities toward stable disease-suppressive states. Several strategies are emerging. The first is direct inoculation with single strains or SynComs. Defined communities can provide complementary functions and greater ecological redundancy than individual biocontrol agents, as demonstrated in tomato, watermelon, and barley pathosystems (Zhou et al., 2022; Qiao et al., 2024; Rigerte et al., 2026). However, introduced organisms must compete with established native communities, survive variable temperature and moisture, colonize the appropriate root zone, and retain activity across plant developmental stages.

A second strategy is host-mediated microbiome engineering. Rather than adding microbes, crops can be selected or bred for root traits and exudate profiles that consistently recruit protective taxa. The RIN study in tomato illustrates that a plant regulatory gene can alter metabolites, Streptomyces recruitment, and bacterial-wilt resistance, while intercropping experiments show that neighboring plants can redirect exudation and beneficial colonization (Yang et al., 2023b; Zhou et al., 2023). Such results create opportunities for “microbiome-assisted breeding” and for prebiotic amendments composed of metabolites that selectively stimulate resident beneficial organisms (Spooren et al., 2024). Agronomic practices offer a third route. Crop rotation, intercropping, composts, organic amendments, reduced disturbance, and diversified plant inputs can modify microbial resource availability and network structure, sometimes increasing suppressiveness (Obiazikwor et al., 2025; Liu et al., 2026). Yet management effects are strongly context-dependent. A microbial treatment effective in sterilized substrate may fail in field soil because indigenous competitors, edaphic chemistry, climate, pesticide history, and local pathogen populations alter establishment and function. Therefore, field translation requires experiments that measure not only disease severity but also inoculant persistence, microbiome succession, functional gene expression, yield, and consistency across sites and seasons (Du et al., 2025). Multi-omics technologies can improve this transition by connecting taxonomy to mechanism. Amplicon sequencing identifies community shifts, metagenomics reveals functional potential, metatranscriptomics identifies active pathways, metabolomics characterizes chemical exchange, and culture collections allow direct reconstruction and testing of candidate consortia (Andargie et al., 2023; Li et al., 2024). Longitudinal sampling is particularly valuable because microbiome states associated with future disease may emerge before pathogen abundance or symptoms become diagnostic (Gu et al., 2022).

The next generation of microbiome-based disease management should therefore prioritize function, ecological stability, and host compatibility rather than maximizing microbial diversity alone. Standardized formulation, shelf-life, biosafety, non-target effects, horizontal gene transfer risk, and regulatory classification must also be addressed before complex living products are widely deployed (Liu et al., 2026). A realistic goal is to integrate microbiome engineering with resistant cultivars, cultural control, diagnostics, and judicious pesticide use. In this framework, the rhizosphere biological shield becomes a manageable component of integrated disease management rather than a stand-alone replacement for all conventional measures (Spooren et al., 2024). Recent synthesis of tomato Fusarium wilt management similarly favors integrating biological control with host resistance and complementary measures rather than relying on a single intervention (Kanwal et al., 2024).

6. Conclusion

The rhizosphere microbiome functions as a dynamic biological shield by combining ecological exclusion, nutrient competition, antimicrobial activity, cross-kingdom cooperation, and activation of plant immunity. Recent studies show that plants actively shape this shield through root exudates and genetic regulation, particularly during pathogen attack, while disease-suppressive soils demonstrate that protective microbial states can emerge at ecosystem scale. Synthetic communities now allow these functions to be reconstructed experimentally and, in some cases, transferred to susceptible plants. The central challenge is moving from controlled demonstrations to predictable field performance. Future microbiome-based protection will depend on identifying causal functions, selecting compatible microbial consortia, exploiting host traits that recruit beneficial organisms, and accounting for soil and environmental context. Integration of longitudinal microbiome profiling, metabolomics, functional omics, and microbiome-assisted breeding should make disease-suppressive rhizospheres increasingly designable. Used alongside conventional integrated disease management, this approach offers a biologically grounded path toward more durable and environmentally compatible crop protection.

Abstract
Penicillium expansum causes apple blue mould and may contaminate fruit with patulin. This study evaluated iPBS retrotransposon primers for preliminary molecular characterization of apple-derived isolates from Sivas, Giresun, Isparta, and Amasya, Türkiye. Following species-targeted PCR with PEF/PER, 29 iPBS primers were screened in eight isolates (P1-P8). The annealing temperatures shown in the gel images were used throughout: 14 primers at 50 °C, four at 51 °C, ten at 52 °C, and one at 53 °C. On visual inspection, iPBS-2402, -2244, and -2381 at 50 °C; -2398 at 51 °C; 2252, 2376, and 2087 at 52 °C; and 2401 at 53 °C were shortlisted because their profiles included several readable bands and apparent differences among isolates. Profiles with a dominant shared band, weak amplification, or extensive smearing were less suitable for unambiguous scoring. The interpretation concerns primer suitability in this eight-isolate pilot, not a completed population-genetic analysis. Neither independent PCR replicates nor a verified presence/absence matrix were supplied; therefore, polymorphism rates, genetic distances, and geographic structure were not calculated. Reproducibility should be confirmed at the gel-image temperatures before the primers are used on the larger isolate collection. The present results define experimentally grounded conditions for that follow-up while keeping species identification, band-based fingerprinting, and quantitative diversity estimation analytically distinct.
Keywords: *Penicillium expansum*; iPBS; retrotransposon; molecular characterization; primer optimization.

Introduction

Penicillium expansum is a principal cause of blue mould in stored pome fruit, and its capacity to produce patulin makes reliable monitoring relevant to both postharvest losses and food safety (Luciano-Rosario el al., 2020). Molecular confirmation of species identity and assessment of variation within a confirmed species address different questions. Previous work documented variation among *P. expansum* strains associated with different hosts, while recent regional studies have emphasized differences in Penicillium sp. composition and patulin production (Sanzani et al., 2013; Dudaš et al., 2025).

Inter-primer binding site amplification targets genomic intervals between primer-binding sites of LTR retrotransposons. Its use does not depend on prior sequence characterization of the study organism (Kalendar et. al., 2010). For diversity analysis, however, the value of a primer depends on distinct and reproducible differences among isolate profiles, rather than on band number or intensity alone. We therefore screened 29 iPBS primers to identify informative candidates and their reported best annealing temperatures for subsequent genetic characterization of *P. expansum* isolates. An iPBS band difference does not, by itself, demonstrate a new retrotransposon insertion or element activity: primer binding and the distance between target sites also affect amplification.

Species identification is a distinct requirement from within-species fingerprinting. In a Serbian survey, Žebeljan et al. (2021) recovered *P. expansum* together with *P. crustosum* and *P. solitum* from stored pome fruit and used multilocus evidence to clarify species boundaries. Shen et al. (2024) similarly examined 62 *Penicillium* strains from diseased apples in China with ITS, BenA, and CaM sequence data and resolved several species associated with blue mould. These findings justify the separation of the

species-targeted PEF/PER assay from the subsequent iPBS diversity screen; variation in an iPBS gel is not by itself evidence of species identity.

Biological variation within *P. expansum* creates a second analytical question. Sanzani et. al. (2013) investigated strains from apple, sweet cherry, and table grape and described variation linked to host of origin. Maldonado et al. (2022) studied 103 isolates from Argentina and Spain through morphological, metabolomic, and β-tubulin approaches; despite similarities in several phenotypic traits, the sequence analysis resolved multiple haplotypes. The latter result illustrates why a marker set should be evaluated for its capacity to distinguish isolates that may otherwise look similar. In the present pilot, however, all documented source material was apple and no provincial mapping of P1-P8 was supplied.

The rationale of iPBS is the presence of primer-binding sites associated with LTR retrotransposons dispersed across eukaryotic genomes. Kalendar et al. (2010) established a method that does not require a target-genome sequence for initial primer development. Özer et al. (2016) applied the approach to multiple fungal taxa and obtained discriminatory fingerprints. Their study supports the feasibility of an iPBS screen in fungi, but its numerical polymorphism results cannot be transferred to this *P. expansum* primer set. Band quality and discriminatory capacity must be measured under the DNA, reaction, annealing, and electrophoresis conditions of the current experiment.

The aim was to compare the amplification profiles of 29 iPBS primers in eight P-coded isolates, identify bands that can be scored consistently, and report the primer-specific annealing temperatures recorded in the gel images. These images represent the selected outcomes of gradient PCR. In the absence of a replicate band matrix, this work establishes a shortlist for validation, rather than a numerical ranking of marker informativeness or an estimate of population structure.

Genome-based evidence shows that isolates assigned to *P. expansum* cannot be assumed to be genetically uniform. Julca et al. (2016) compared seven geographically separated *P. expansum* genomes and described within-species genomic variation and patterns consistent with recombination. Their findings support molecular comparisons among regional isolates, while the modest genome sample limits population-level inference. PCR fingerprints do not provide the resolution of genome sequencing; here, the immediate objective of iPBS screening is to find primers yielding distinguishable, reproducible fragments.

The biological relevance of isolate variation extends beyond distinguishing fingerprints. Samaras et al. (2020) investigated efflux-transporter overexpression in fungicide multidrug-resistant *P. expansum* strains at the transcriptome level; Luciano-Rosario et al. (2023) used functional genetics to investigate candidate loci affecting virulence during apple decay. These studies address questions that require independent experiments. An anonymous iPBS fragment alone cannot establish fungicide resistance, patulin production, or virulence.

Materials and Methods

Isolates and DNA preparation

Single-spore purification was documented for the stock isolates. Variable DNA concentrations or degraded templates can produce inconsistent dominant-marker bands, so DNA concentration and integrity were checked before PCR. P1-P8 showed the eight separate lanes per primer in the screening images. The original stock collection may contain additional isolates; the gel images do not show that all stocks were screened. Dates, cultivar names, storage sites, and the individual province for each P code were unavailable, precluding any attribution of band differences to those factors.

The stock collection consisted of single-spore isolates recovered from apples collected in Sivas, Giresun, Isparta, and Amasya, Türkiye. Eight isolates coded P1-P8 were represented in the supplied iPBS gel images. As no mapping between P codes and provinces was supplied, no geographic grouping was assigned. Genomic DNA was prepared using a modified CTAB procedure; concentration and purity were assessed spectrophotometrically, DNA integrity was checked on 1% agarose, and extracts were adjusted to approximately 40-50 ng/µL.

PCR conditions for isolate species identification

Species-targeted PCR used PEF (5′-ATCGGCTGCGGATTGAAAG-3′) and PER (5′-AGTCACGGGTTTGGAGGGA-3′), with a 404-bp expected amplicon in the supplied protocol. A 10-µL reaction contained 5 µL of 2× Phanta Max Master Mix, 0.5 µL of each primer, 1 µL of DNA, and 3 µL of water. Cycling comprised 95 °C for 3 min; 35 cycles of 95 °C for 15 s, 58 °C for 15 s, and 72 °C

for 15 s; and 72 °C for 5 min. The laboratory notes report positive identification, but a separate species-diagnostic gel was not supplied for independent isolate-level assessment.

PCR conditions for iPBS genetic-diversity screening

Primer sequences were transcribed from the accompanying spreadsheet. Annealing temperatures were transcribed exclusively from the labels embedded in the six gel images. Eight P-coded isolate lanes were compared for each primer. An iPBS reaction used one primer to generate a multilocus fingerprint; the species-targeted PEF/PER assay used a forward and reverse primer pair. The molecular-size ladder aids approximate assessment of fragment mobility, but precise fragment sizes were not assigned from these composite gel images. The qualitative decision rule emphasized clear bands above background, interpretable amplification in several of the eight lanes, and visually distinct presence or absence at corresponding migration levels. Brightness by itself was not treated as a genetic variant, and diffuse smear or faint uncertain signal was not scored as an allele. No numerical band counts, reproducibility estimates, or polymorphism percentages were derived in the absence of replicate gels and an independently checked binary matrix.

The reported 20-µL iPBS reaction comprised 2 µL of PCR buffer, 2 µL of dNTP solution, 5.6 µL of water, 3.2 µL of a single primer, 2 µL of $MgCl_2$ solution, 0.2 µL of Taq polymerase (5 U/µL), and 5 µL of DNA. As the stock/final concentration notation in the laboratory notes is ambiguous, only component volumes are reported here. Cycling comprised 95 °C for 3 min; 30 cycles of 95 °C for 15 s, primer-dependent annealing for 1 min, and 72 °C for 1 min; and 72 °C for 5 min. The general laboratory protocol lists a 50-65 °C annealing range; the selected gradient-PCR gel images record primer-specific working temperatures of 50, 51, 52, and 53 °C. Products were resolved in 2% agarose with 1× TBE at 115 V for 2 h 40 min using a 100-3000-bp ladder. Gel interpretation was qualitative.

Findings and Discussion

The gel images show 14 primers at 50 °C, four at 51 °C, ten at 52 °C, and one at 53 °C. These temperatures, embedded in the images as outcomes of gradient PCR, were used for every primer in both tables. iPBS-2402, 2244, and 2381 (50 °C), 2398 (51 °C), 2252, 2376, and 2087 (52 °C), and 2401 (53 °C) offered the most promising visually interpretable fingerprints (Table 1, 2; Figures 1-6). This selection rests on readable, potentially differentiating bands in the P1-P8 lanes. It is provisional because repeatability and information content have not been quantified.

Table 1. Sequences of all 29 screened primers and annealing temperatures transcribed from the six gel images

Primer	Sequence (5′-3′)	Gel-image T_a
iPBS-2074	GCTCTGATACCA	50 °C

Table 2. iPBS primers shortlisted by visual inspection and their gel-image annealing temperatures.

Primer	Sequence (5′-3′)	Gel-image T_a	Qualitative reading
iPBS-2402	TCTAAGCTCTTGATACCA	50 °C	Multiband candidate
iPBS-2244	GGAAGGCTCTGATTACCA	50 °C	Multiband candidate
iPBS-2381	GTCCATCTTCCA	50 °C	Multiband candidate
iPBS-2398	GAACCCTTGCCGATACCA	51 °C	Distinct levels
iPBS-2252	TCATGGCTCATGATACCA	52 °C	Multiband candidate
iPBS-2376	TAGATGGCACCA	52 °C	Multiband candidate
iPBS-2087	GCAATGGAACCA	52 °C	Common bands; rescore
iPBS-2401	AGTTAAGCTTTGATACCA	53 °C	Multiband candidate

Predominantly shared strong bands in iPBS-2384 and -2257 may offer limited discrimination, whereas iPBS-2380 and -2255 amplified weakly. In iPBS-2246, 2399, and 2387, intense or smeared regions complicate reliable band calls. iPBS-2087 shows sharp products, yet its apparently shared bands make quantitative discrimination uncertain until scored. Consequently, this pilot does not establish a polymorphism percentage or demonstrate a geographic population structure. Replicate amplifications, matched DNA input, negative controls, and independent binary scoring are prerequisites for such analyses. This interpretation is consistent with the need to distinguish the measurement of within-species variation from the prior species-diagnostic PCR (Sanzani el al., 2013).

The gel images reveal substantial differences in primer performance. At 50 °C, iPBS-2074 produced some apparent lane differences, but uneven amplification weakened its priority. A strong common product dominated iPBS-2384, which could conceal weaker discriminating fragments; products from iPBS-2245 and 2382 were often faint. In contrast, iPBS-2402 produced a more consistently interpretable multilocus profile, and iPBS-2244 and -2381 showed several visible levels suitable for follow-up. These observations motivate retesting rather than a claim that any primer already has a measured information content. At 51 °C, iPBS-2398 yielded several discernible fragment levels. iPBS-2249 also amplified, although diffuse fluorescence in some lanes complicates binary scoring; iPBS-2400 produced fewer confidently distinctive levels. The separate 52 °C gel image shows iPBS-2252 and 2376 with several potentially scorable products. The same image also contains iPBS-2391, 2399, and 2375. Their temperatures in this study are all 52 °C, as printed on that image; no annealing temperatures were assigned from the primer spreadsheet. The later gel images include readable products for iPBS-2087 at 52 °C and iPBS-2401 at 53 °C. The relatively strong shared fragments of iPBS-2087 may ultimately reduce its discriminatory value even if amplification proves reproducible. Some iPBS-2401 lanes differ in intensity, but intensity is not equivalent to band presence or absence. iPBS-2387 and -2399 show regions of saturation or extensive smearing and were not chosen for immediate scoring. Matched template input, exposure, gel conditions, and a second PCR run are necessary to distinguish technical signal variation from reproducible polymorphism.

Özer et al. (2016) found that iPBS markers can differentiate fungal isolates across several taxa. Their conclusions provide a methodological comparator, although their reported polymorphism estimates arise from a different species set and systematically scored bands. Maldonado et. al. (2022) compared Argentine and Spanish *P. expansum* isolates using β-tubulin haplotypes. Our proposed dominant-marker

screen neither reproduces their sequence-based test nor estimates comparable diversity indices; it identifies primers worth applying to a larger sample. In both comparisons, an assay's suitability must be assessed in the context of its sampling and scoring design. The multilocus species analyses of Žebeljan et al. (2021) and Shen et al. (2024) further support separating species confirmation from subsequent within-species variation. A positive PEF/PER note is useful, but the diagnostic gel and sequence confirmations were not part of the provided figure set. Dudaš et al. (2025) compared *Penicillium* species in relation to patulin production; no toxin assay, virulence test, or fungicide phenotype was performed in the present marker screen. Accordingly, the observed iPBS bands cannot be interpreted as evidence of patulin production or pathogen aggressiveness.

For a future quantitative study, ambiguous fragments should be excluded. A band should enter the 1/0 matrix only if it reappears at the same migration position in independent PCRs and can be scored without knowing isolate identity. Only then can Jaccard similarities, ordination, and clustering be estimated. Tests of provincial differentiation also require a sample design and metadata matching each isolate to its collection site. The expression "best primers" in this paper refers solely to a qualitative shortlist from the available gel images, not to a ranked numerical polymorphism index. Temperatures refer to the values printed on the corresponding gel images.

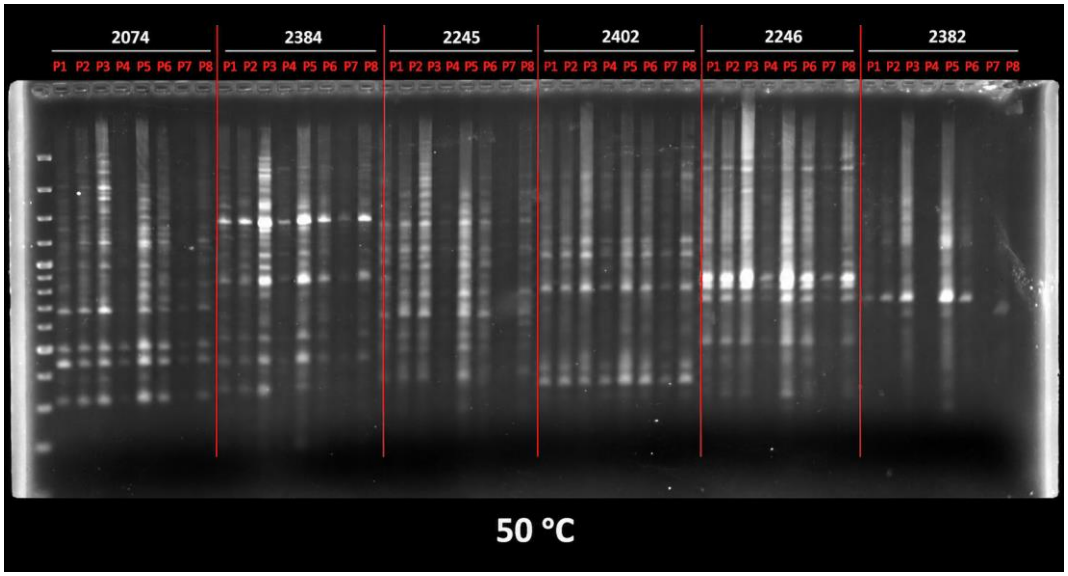

Figure 1. Gel image at 50 °C across eight P-coded isolates; iPBS-2402 is a priority candidate.

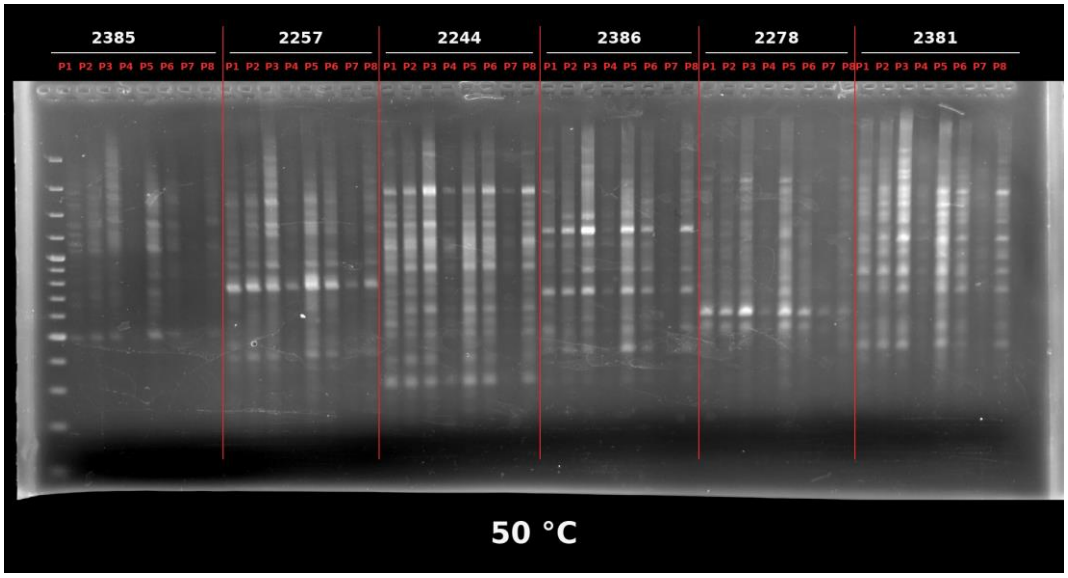

Figure 2. Gel image at 50 °C; iPBS-2244 and -2381 are shortlisted for confirmation.

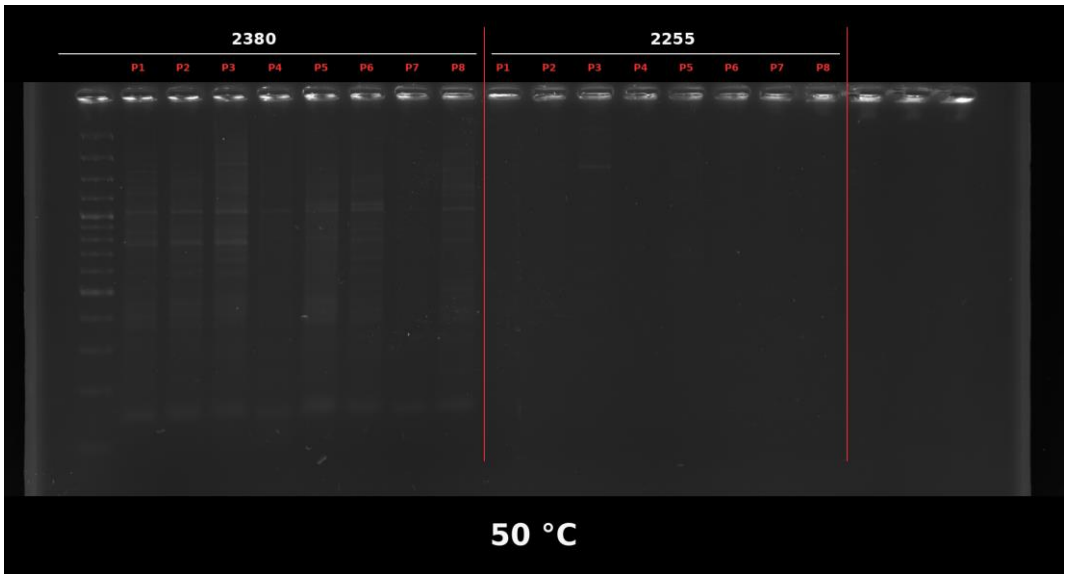

Figure 3. Gel image at 50 °C showing weak amplification with iPBS-2380 and -2255.

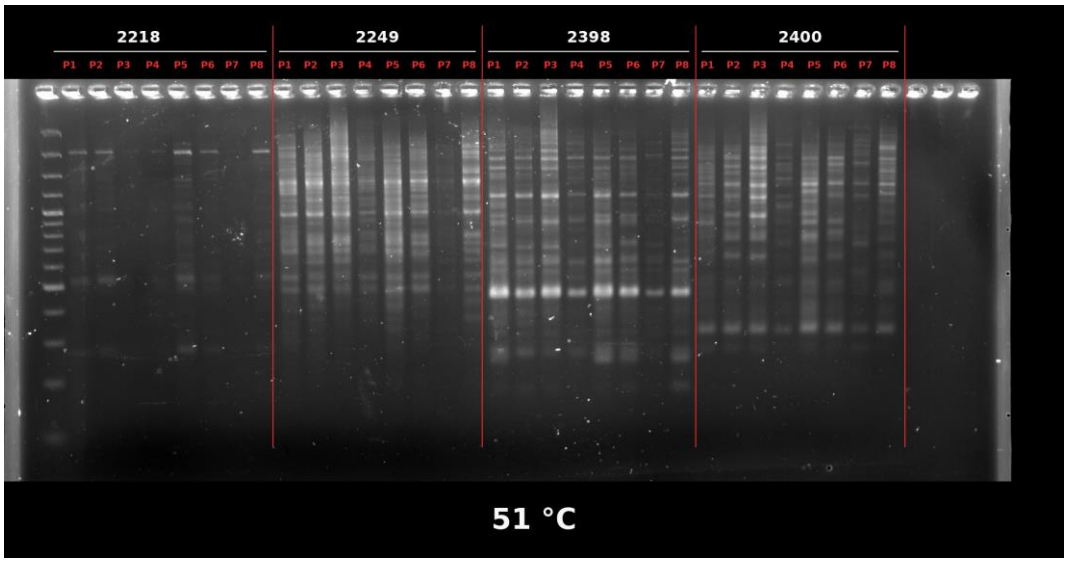

Figure 4. Gel image at 51 °C including iPBS-2398; diffuse products of other primers need confirmation.

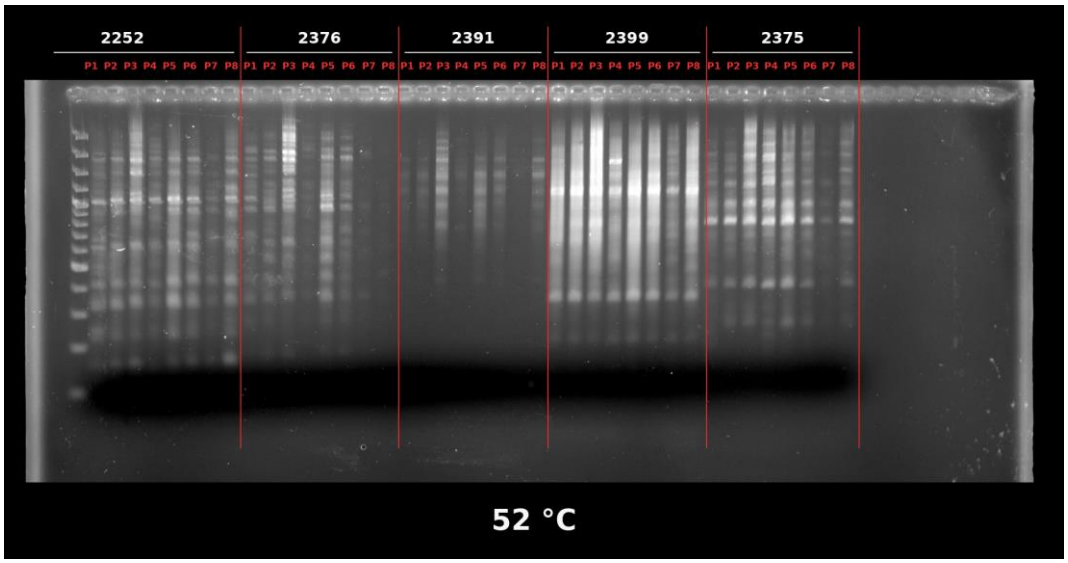

Figure 5. Gel image at 52 °C showing iPBS-2252 and -2376 among the screened primers.

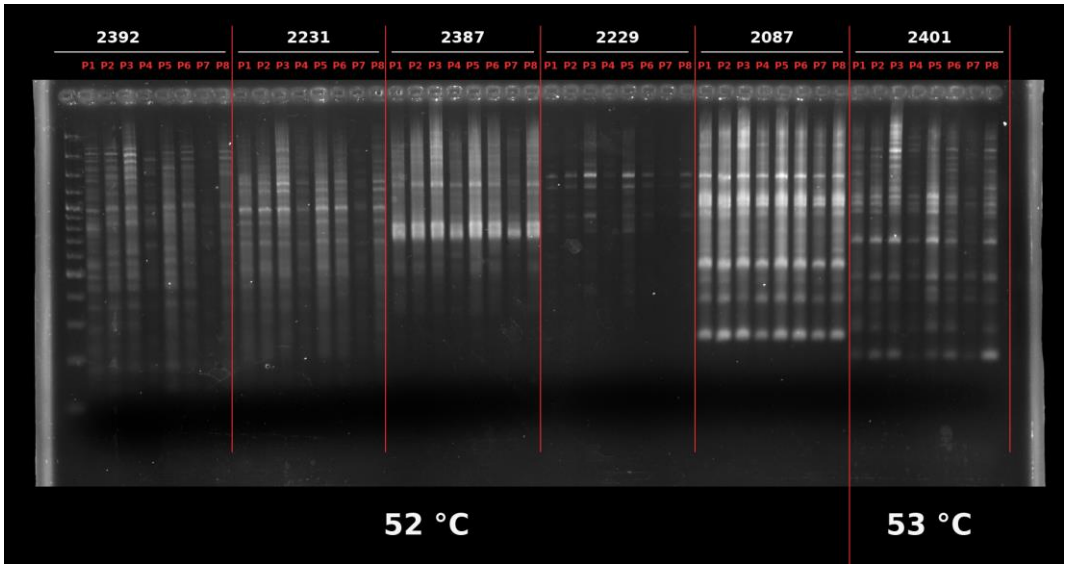

Figure 6. Gel image showing iPBS-2087 at 52 °C and iPBS-2401 at 53 °C.

Evidence from other microorganisms helps place the iPBS screen in a methodological context. Aydın et al. (2022) applied iPBS to 96 Saccharomyces cerevisiae isolates sampled across four Turkish regions to examine genetic diversity and population structure. Primer performance in yeast cannot be transferred directly to Penicillium, because the distribution of amplifiable sites and band quality depend on the organism and PCR conditions. Accordingly, the ranking derived from gel images of eight isolates is a preliminary selection for P. expansum, rather than a measured discriminatory-power estimate supported by replicate genotyping.

The genomic variation documented by Julca et al. (2016) supports extending this study to a larger isolate collection if the selected fragments prove reproducibly polymorphic. Samaras et al. (2020) and Luciano-Rosario et al. (2023), however, addressed fungicide response and virulence through distinct functional approaches. The present iPBS bands have not been validated as diagnostic markers for these traits. A future assessment of possible associations with patulin concentration, fungicide sensitivity, or fruit pathogenicity would require independent phenotype measurements, more isolates, and appropriate statistical validation.

Conclusion and Recommendations

The qualitative assessment of 29 iPBS primers in eight P-coded isolates shortlisted iPBS-2402, -2244, -2381, -2398, -2252, -2376, -2087, and -2401. The selected annealing temperatures shown in the gel images were 50, 51, 52, and 53 °C, depending on the primer. Specifically, 2252 and 2376 belong to the 52 °C gel image. Distinct bands are candidate markers only after they prove reproducible in independent amplifications. A validated presence/absence matrix and a broader, traceable isolate sample are prerequisites for diversity indices and comparisons among collection sites. First, each P1-P8 code should be linked to its stock number, province, collection date, apple cultivar, and any recorded storage environment. The species-diagnostic gel image, negative control, and ideally confirmatory multilocus sequence records should be linked to the same identifiers. Traceable sample identities will make it possible to distinguish biological differences from specimen mislabelling or mixed cultures. Documentation of single-spore purification is essential when a later banding pattern is assigned to one isolate. Second, the shortlisted primers should be reamplified at the temperatures printed in their gel images: 50 °C for 2402, 2244, and 2381; 51 °C for 2398; 52 °C for 2252, 2376, and 2087; and 53 °C for 2401. At least two independently prepared PCRs with matched DNA input are needed to establish reproducibility. Stock and final concentrations of primer, buffer, nucleotides, $MgCl_2$, and template must be confirmed from laboratory records before a transferable protocol is published. Diffuse or saturated products warrant systematic optimization of template input and reaction specificity. Third, the final primer set should be evaluated through blind binary scoring by two readers of bands that are sharp and replicated. Any disagreement should be resolved by repeating the gel, after which total and polymorphic

band counts and isolate similarities can be calculated. A larger collection balanced across provinces and collection contexts would then support explicit tests of geographic structure. Phenotypes such as toxin output or virulence could be evaluated separately if measured. This sequence of work turns the current optimization pilot into a defensible genetic-diversity study without assigning unsupported statistics to the preliminary gels.

Abstract
Penicillium expansum is a major cause of blue mould in stored apples and is associated with patulin contamination. This study screened start codon targeted (SCoT) primers as candidates for future genetic diversity analysis of apple-derived *P. expansum* isolates. Single-spore stock cultures from Sivas, Giresun, Isparta, and Amasya were subjected to species-targeted PEF/PER PCR, while the available SCoT gel images show four coded isolates (P1-P4). Eighteen primer labels occur across two gel images; the accompanying sequence spreadsheet contains 18 primer entries, but lists SCoT-25 where the image identifies SCoT-26. Consequently, 17 imaged labels can be matched unambiguously to supplied sequences; the SCoT-26 sequence requires confirmation and SCoT-25 cannot be scored from these images. The documented SCoT protocol used annealing at 50 °C. Visual assessment prioritised SCoT-3, -5, -19, and -22 for repeatability testing; SCoT-1 and -2 are secondary candidates. Intense common bands, faint lanes, and background signal lowered confidence in several other primers. These observations identify candidates, not measured polymorphism rates or population structure. Independent PCRs, explicit band scoring, resolution of the primer-label discrepancy, and a larger provenance-balanced isolate set are required before diversity parameters can be reported.
Keywords: *Penicillium expansum*; SCoT; apple blue mould; primer screening; genetic diversity; agarose gel.

Introduction

Postharvest blue mould of apple is closely associated with *Penicillium expansum*. The pathogen can colonise wounded fruit during handling and cold storage, and its ability to produce patulin makes isolate monitoring relevant to food safety as well as product loss (Luciano-Rosario et al., 2020). Yet a blue mould lesion does not establish species identity: several *Penicillium* species may coexist in stored fruit. Species confirmation and comparisons within a confirmed species are therefore separate analytical steps. Recent surveys of apples and other pome fruit recovered multiple *Penicillium* species and showed that pathogenicity and toxin production should be evaluated independently (Žebeljan et al., 2021; Shen et al., 2024; Dudaš et al., 2025). Understanding variation among *P. expansum* isolates is relevant when designing collections for epidemiological studies and selecting strains for subsequent functional work. Sanzani et al. (2013) investigated variation related to host of origin, whereas Maldonado et al. (2022) combined morphological, β-tubulin, and metabolomic observations on isolates from Argentina and Spain. A comparison of genome sequences also demonstrated measurable intraspecific variation in geographically distributed *P. expansum* isolates (Julca et al., 2016). Results from these studies cannot be assigned to the present isolates without matched phenotypic or sequence data; instead, they justify first establishing a reproducible marker set.

Start codon targeted polymorphism is a single-primer amplification method developed from a short conserved region around the ATG translation initiation codon in plant genes (Collard & Mackill, 2009). Because the target concept concerns gene-associated sequence motifs, SCoT primers are often described as gene-targeted; a product's genomic position or function, however, must be established by sequencing before it can be called a functional marker in a particular fungus. The original assay yielded predominantly dominant profiles, so presence and absence of reproducible amplicons, rather than band

intensity alone, form the basis of fingerprint analysis (Collard & Mackill, 2009). The adaptation of SCoT to fungi is supported by independent examples, but primer performance is not portable across taxa. Aydın et al. (2022) investigated yeast isolates from Turkish sourdough, and Gajera et al. (2016) studied mycoparasitic *Trichoderma koningii* using SCoT-derived variation. Palacıoğlu et al. (2023) assessed multiple plant-pathogenic fungal species with SCoT markers, and Özer et al. (2026) examined Fusarium from wheat. Together these studies show that fungal SCoT amplification is feasible while also making clear that a fungal primer screen requires species-specific and experiment-specific assessment. Molecular marker studies distinguish technical amplification, reproducibility, and biological informativeness. A bright product shared by all isolates confirms amplification but may carry little discriminatory information. Conversely, an apparent absence in a faint lane could reflect low DNA input, amplification failure, or variation at a priming site. Oliveira and Azevedo (2022) reviewed the diversity of fungal marker systems and their distinct analytical uses. For the present four-isolate screen, the immediate questions are which labelled primer groups yield discrete, interpretable fragments and which issues in the supplied records must be resolved before quantitative analysis.

Our objective was to examine the two supplied SCoT gel images, link their labels to the supplied sequence list, and prioritise primers for a reproducible *P. expansum* fingerprinting workflow. We retain the species-specific identification assay and the reported SCoT PCR conditions as separate methodological stages. We deliberately restrict conclusions to the observed four-lane gel profiles: no repeat amplification records, scored binary matrix, phenotypes, or isolate-to-province mapping were supplied. Thus the work is an evidence-based primer selection and documentation study rather than a completed population-genetic analysis.

Materials and Methods

Isolates and DNA preparation

The source protocol describes pure, single-spore isolates recovered from apples collected in Sivas, Giresun, Isparta, and Amasya, Türkiye. Cultures were maintained in the stock collection at -80 °C and +4 °C. The two provided SCoT gel images label four isolate lanes per primer (P1-P4), and no province-by-code map is available; statements about geographic grouping or allele frequencies therefore cannot be made. Mycelial material was collected by centrifugation of suspensions in sterile water or by scraping from culture plates. Genomic DNA was isolated using a modified CTAB-based procedure, checked by spectrophotometry and a 1% agarose gel, and stored at -80 °C. The source notes 40-50 ng/µL for prepared stocks; the amount stated for each subsequent PCR is reported separately because the dilution between these stages is not specified.

PCR conditions for isolate species identification

The species-directed reaction used PEF (5′-ATCGGCTGCGGATTGAAAG-3′) and PER (5′-AGTCACGGGTTTGGAGGGA-3′), for an expected 404-bp product as described in the supplied PCR record and linked there to Sanzani et al. (2013). A 10-µL reaction comprised 5 µL 2× Phanta Max Master Mix (Vazyme P525), 0.5 µL of each forward and reverse primer (listed as 10 pM in the source), 3 µL nuclease-free water, and 1 µL template DNA (50 ng/µL in the source table). Cycling was 95 °C for 3 min; 35 cycles of 95 °C for 15 s, 58 °C for 15 s, and 72 °C for 15 s; followed by 72 °C for 5 min. The source describes positive species-directed results in stock isolates; the supplied SCoT photographs themselves do not contain a separately labelled PEF/PER gel, so their bands are not used to reconfirm species identity.

PCR conditions for SCoT genetic diversity screening

The recorded 20-µL single-primer amplification mixture contained 2 µL PCR buffer, 2 µL dNTP solution, 5.6 µL distilled water, 3.2 µL primer, 2 µL $MgCl_2$ solution, 0.2 µL Taq DNA polymerase (5 U/µL; 1 U/reaction), and 5 µL genomic DNA (25 ng stated in the protocol). The supplied record describes buffer as 1×, dNTPs as 2 mM, primer as 5 mM, and $MgCl_2$ as 2 mM without consistently distinguishing stock concentrations from final concentrations; these labels are transcribed as recorded and require laboratory-sheet verification before replication. The program states 95 °C for 5 min and 35 cycles including 95 °C for 1 min and 50 °C annealing for 1 min, followed by 72 °C for 8 min. The duration of a within-cycle 72 °C extension is absent from the record and is not invented here. The 50 °C value comes from the SCoT protocol: unlike the earlier iPBS material, neither SCoT gel image prints a primer-specific gradient temperature.

Gel electrophoresis and source reconciliation

Products were resolved on 2% agarose in 1× TBE at 115 V for 2 h 40 min. A GeneRuler 100-3000 bp marker (Thermo Scientific, SM0333) is specified in the PCR record. Slide images were reviewed at their original pixel resolution, retaining the original image labels rather than redrawing bands. Primer sequences were transcribed from the supplied spreadsheet; the gel names SCoT-26, which the sequence sheet omits, while the sheet lists SCoT-25, which does not appear on either gel. This discrepancy was treated as unresolved rather than silently mapping the sequence of SCoT-25 to SCoT-26.

Primer evaluation and limits of scoring

Primers were assessed qualitatively for visible amplification in P1-P4, discrete bands, between-lane differences potentially suitable for scoring, background smearing, signal saturation, and missing or very faint lanes. Bands were not converted into a binary matrix because independent PCR repeats, exposure calibration, and lane-to-isolate metadata were unavailable. No polymorphic-band percentage, resolving power, polymorphic information content, similarity coefficient, dendrogram, AMOVA, or inferred population structure was calculated. The shortlist identifies candidates for validation, not empirically ranked genetic-diversity estimates.

Findings and Discussion

The two source gel images together display 18 primer labels: SCoT-1, -2, -3, -5, -6, -8, -9, -11, -12, -13, -14, -16, -19, -21, -22, -23, -24, and -26. Each region is annotated with P1-P4, but the formatting of SCoT-12 and -16 places one P4 annotation away from its primer heading; precise lane alignment in that area should be confirmed against the original gel notebook. The image sequence corresponds to Table 1, except for the SCoT-25/SCoT-26 mismatch. Matching only by apparent band pattern cannot fix a primer-identity error. On the first gel image, SCoT-3 produces several discernible bands across P1-P4, with apparent differences in the lower-to-mid migration region. SCoT-5 also yields relatively readable bands in all four lanes, although the strongest products are shared. These two primers are primary candidates because multiple clear features can be revisited in independent reactions. SCoT-1 gives a multilocus profile, with additional lower bands of variable apparent visibility; its lane background and faint features warrant a conservative secondary priority. SCoT-2 contains a pronounced lower shared band and some higher fragments that might help distinguish lanes, but dominant common signal limits the confidence of a single-image assessment.

SCoT-6 has little convincing amplification in the supplied image and cannot support diversity scoring in its present form. SCoT-8 shows marked lane-to-lane imbalance, including weak or absent signal in a central lane, which cannot be interpreted as a genotype-specific null band without repeat amplification. SCoT-9 produces bright, partly saturated products and diffuse background. Strong common products and high signal are prominent in SCoT-11 and -14; SCoT-12 has limited clearly separable features in the shown lanes. SCoT-13 is relatively faint, while SCoT-16 includes strong shared bands but uncertainty in the final lane annotation. These primers are not assigned quantitative informativeness from the photographs alone. On the second gel image, SCoT-19 provides several resolved bands across four lanes and visible differences in band occurrence or strength at more than one migration level. Because the last lane appears weaker for some products, this is a promising primer whose candidate polymorphisms need strict technical replication. SCoT-22 shows multiple products, including lower bands suitable for checking across P1-P4; despite some uneven background, it is another primary candidate. SCoT-21 is dominated by a common band, whereas SCoT-23 has a strong lower product and less clear information above it. SCoT-24 has multiple products but conspicuous lane streaking and strong common fragments, making it a conditional reserve primer.

The final gel group bears the label SCoT-26 and contains visible amplification in P1-P4, but its sequence is absent from the supplied list. No sequence is provided for a reliably identifiable SCoT-26 primer; any recommendation to order or reproduce it would risk using the unrelated SCoT-25 sequence. Conversely, SCoT-25 has a listed sequence but no corresponding image-based performance result. The mismatch affects one of 18 imaged names and one of 18 listed sequences; the other 17 name-to-sequence pairs are directly reconcilable.

Based on readable fragment distributions rather than a numerical polymorphism score, SCoT-3, -5, -19, and -22 constitute the principal shortlist. SCoT-1 and -2 may be retained as secondary candidates if repeat experiments confirm their weaker or more ambiguous features. This order is intentionally provisional: a primer with numerous shared bands may prove less informative than one with fewer but

repeatable differences, and a visually missing band may become a strong product when template input is standardised. Table 2 records the evidence and conditions that each candidate must meet before inclusion in a final fingerprinting set.

Table 1. Primer labels, supplied sequences and the source reconciliation.

Primer	Sequence (5′-3′)	Source status
SCoT-1	CAACAATGGCTACCACCA	Image + sheet
SCoT-2	CAACAATGGCTACCACCC	Image + sheet
SCoT-3	CAACAATGGCTACCACCG	Image + sheet
SCoT-5	CAACAATGGCTACCACGA	Image + sheet
SCoT-6	CAACAATGGCTACCACGC	Image + sheet
SCoT-8	CAACAATGGCTACCACGT	Image + sheet
SCoT-9	CAACAATGGCTACCAGCA	Image + sheet
SCoT-11	AAGCAATGGCTACCACCA	Image + sheet
SCoT-12	ACGACATGGCGACCAACG	Image + sheet
SCoT-13	ACGACATGGCGACCATCG	Image + sheet
SCoT-14	ACGACATGGCGACCACGC	Image + sheet
SCoT-16	ACCATGGCTACCACCGAC	Image + sheet
SCoT-19	ACCATGGCTACCACCGGC	Image + sheet
SCoT-21	ACGACATGGCGACCCACA	Image + sheet
SCoT-22	AACCATGGCTACCACCAC	Image + sheet
SCoT-23	CACCATGGCTACCACCAG	Image + sheet
SCoT-24	CACCATGGCTACCACCAT	Image + sheet
SCoT-26	—	Image only; sequence unverified
SCoT-25	ACCATGGCTACCACCGGG	Sequence only; no gel image

Note: SCoT-25 has no gel image and SCoT-26 has no verified sequence; neither was substituted for the other.

Table 2. Qualitative candidate primers and the next verification step.

Primer	Priority / visual observation	Validation
SCoT-3	Primary; resolved bands	Repeat lower-middle bands
SCoT-5	Primary; multiband	Verify weaker bands
SCoT-19	Primary; band differences	Check P4 signal
SCoT-22	Primary; several products	Resolve low bands
SCoT-1	Secondary; faint lower bands	Confirm repeatability
SCoT-2	Secondary; common intense band	Score only discrete bands

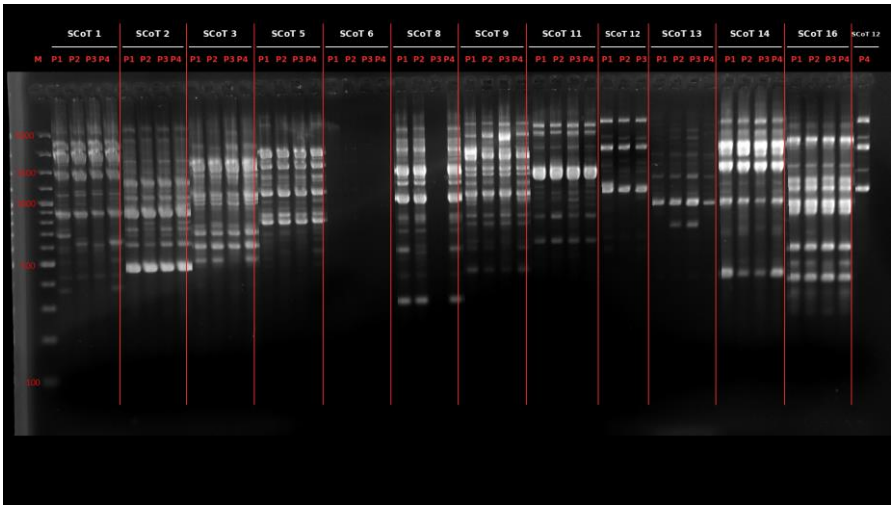

Figure 1. First original SCoT gel image showing the labelled primer groups SCoT-1 through -16 and P1-P4 lanes. Red separators and labels are already part of the supplied image; apparent intensity differences are not scored as quantitative polymorphism.

The labelled regions in this original image are useful for tracing a provisional assessment back to a specific primer and lane. Nevertheless, neighbouring regions share one gel background and differ in signal strength. Interpretation should therefore focus on clearly separated fragments within a primer group, while accounting for uneven lane loading and the possibility that bright common products conceal weaker bands. In particular, the near absence of signal with SCoT-6 and imbalance among SCoT-8 lanes are technical prompts for repeat amplification, not evidence that P-coded isolates lack a corresponding genetic locus.

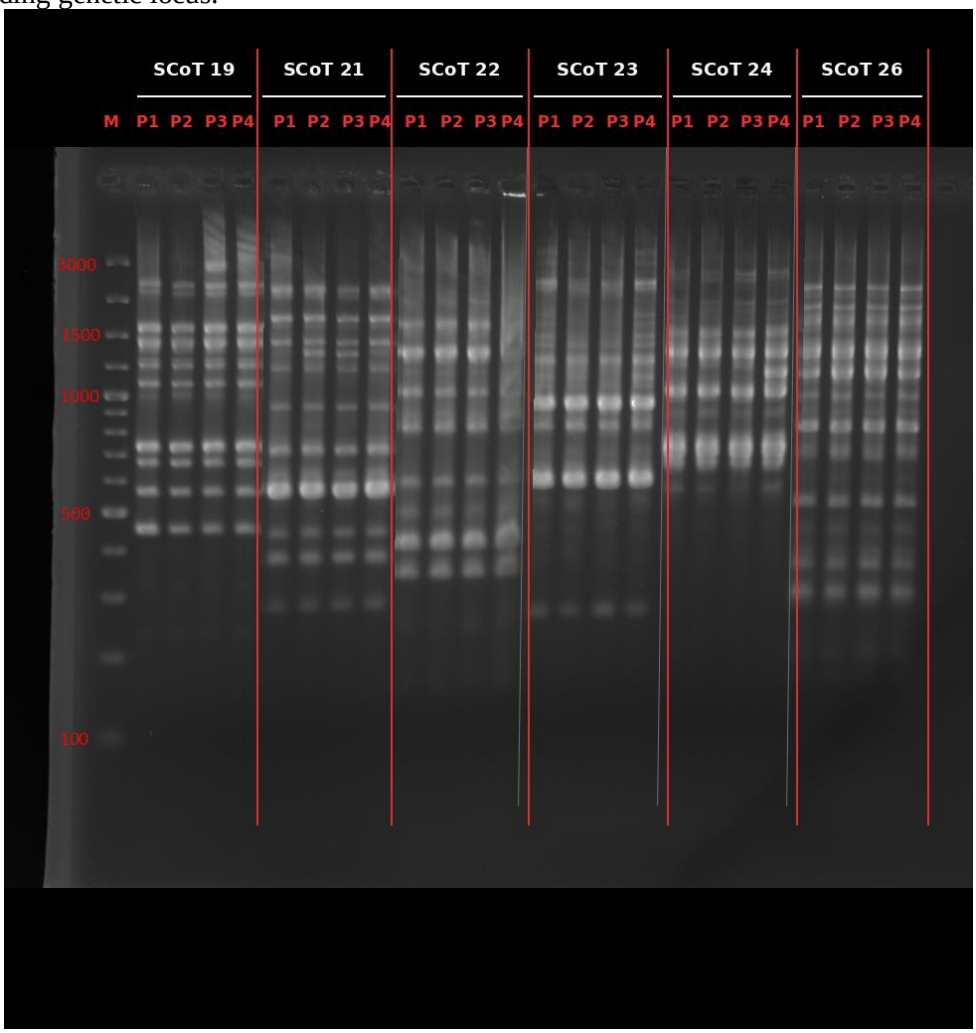

Figure 2. Second original SCoT gel image showing SCoT-19, -21, -22, -23, -24 and photographed SCoT-26. The SCoT-26 primer sequence is not present in the supplied spreadsheet.

An informative primer is not simply the primer producing the most bands. Intense fragments shared by every lane may serve as controls for successful amplification while providing little discrimination. A putative isolate-specific fragment may be more useful, but only if it recurs in separately prepared PCRs. Selection should be based on the number of repeatable variable loci, the proportion of missing data, and the capacity of the combined primer set to distinguish isolates. Without these measures, SCoT-3/-5/-19/-22 is an experimentally motivated candidate set rather than a validated optimal combination. The SCoT name does not establish a functional effect for an anonymous amplified fragment. The original SCoT method relied on single 18-mer primers and 50 °C annealing and explicitly tested reproducibility with independently conducted PCRs (Collard & Mackill, 2009). The current DNA record also specifies 50 °C, but our gels contain neither a printed gradient comparison nor independent technical runs. It would therefore be inaccurate to call 50 °C an experimentally optimised, primer-specific annealing temperature in this dataset. It is the documented working condition for this screen and a starting point for a future small gradient around the recorded setting if nonspecific smears persist.

Several fungal studies offer useful methodological comparisons. Aydın et al. (2022) used SCoT markers in yeast from Turkish sourdough, and Palacıoğlu et al. (2023) evaluated 96 isolates spanning ten fungal species with a larger primer screen before calculating population-level summaries. Gajera et al. (2016) analysed SCoT variation in *T. koningii*, whereas Güney et al. (2023) applied SCoT in Alternaria associated with lemon black rot. Özer et al. (2026) extended the approach to wheat-associated Fusarium. These studies establish biological feasibility in fungal systems; none supplies an estimate of how many polymorphic *P. expansum* loci the present four lanes contain, and transferring published polymorphism percentages here would be misleading.

The first analytical boundary is taxonomic. SCoT primer fragments generated from a mixed *Penicillium* collection could reflect species differences rather than intraspecific variation. Multiple blue-mould-associated *Penicillium* sp. were recovered in published surveys (Žebeljan et al., 2021; Shen et al., 2024; Dudaš et al., 2025). The source record reports PEF/PER-positive *P. expansum* stocks, but the SCoT gels alone are not species-confirmatory evidence. Before comparative analysis, isolate codes should be linked to the diagnostic PCR record and, where feasible, a sequence-confirmed reference for taxonomically ambiguous cultures. The second boundary is biological interpretation. Sanzani et al. (2013) and Maldonado et al. (2022) assessed diversity in *P. expansum* using designs that addressed host or geographic context, while Julca et al. (2016) compared genomes and detected appreciable within-species variation. The four P-coded lanes here have no verified provenance-by-lane key, replication, or scored matrix. Neither a geographic cluster nor a genetic distance can be inferred from visual differences in these images. The bands are candidate dominant loci; two equal-migrating fragments also need not be homologous without sequence confirmation.

A third boundary concerns phenotypic inference. Samaras et al. (2020) investigated multidrug resistance through transcriptomic analysis; Luciano-Rosario et al. (2023) used functional genetics to study virulence in apple. Neither fungicide response, patulin production, nor infection severity was measured for P1-P4 in the supplied record. Even where an eventual SCoT locus lies near a coding region, a band difference alone cannot establish a causal gene or predict any of these phenotypes. Trait association requires isolate-level phenotyping, adequate sample size, and independent validation. The primer identity inconsistency is experimentally consequential. SCoT-25 and -26 are distinct catalogue identifiers; substituting the spreadsheet entry for the photographed name would undermine the reproducibility of any future paper. The PCR record also leaves the within-cycle extension unspecified and labels some reaction constituents ambiguously. Resolution should come from laboratory worksheets, tube labels or purchase records, and original thermocycler programs. Correcting these source fields is part of quality control rather than an opportunity to infer missing values from typical published conditions.

Band-scoring practice determines whether the selected primers ultimately become informative. Replicate products should be imaged under a consistent exposure; clearly separated fragments at the same migration position can then be called present or absent with a documented tolerance. Ambiguous or saturated features should be coded missing, not force-scored. Across a larger balanced isolate collection, one could report total and polymorphic fragments per primer, the proportion of reproducible polymorphic bands, resolving power and binary similarity as applicable. Oliveira and Azevedo (2022) provide context for choosing complementary fungal marker approaches when independent confirmation is needed.

Conclusion and Recommendations

Validation can proceed in three stages. First, repeat P1-P4 with the four primary and two secondary primers in two independently prepared reactions, retaining only reproducible bands. Second, expand the successful set to additional separately collected single-spore isolates whose species identity and sample provenance have been confirmed. Third, compare SCoT and iPBS profiles on the same DNA samples while scorers remain unaware of geographic origin. The chosen primers should be reassessed at each stage: a primer that amplifies cleanly can still fail to reveal reproducible variation in a larger collection. The supplied two SCoT gel images support a carefully bounded primer-screening result. Eighteen primer names were photographed in four isolate lanes per name, and 17 photographed names match sequences in the provided workbook. SCoT-3, -5, -19, and -22 show the most promising combination of visible multi-band amplification and potentially scorable between-lane differences; SCoT-1 and -2 merit secondary testing. The 50 °C annealing condition originates from the SCoT PCR protocol, not a

temperature gradient printed on these images. These recommendations represent a practical shortlist and cannot be interpreted as a numerical ranking of polymorphism or diversity. The first priority is to reconcile the photographed SCoT-26 with the workbook's SCoT-25. A dated primer inventory, oligonucleotide order confirmation, original tube label, and experiment log should establish which primer was amplified. The SCoT-26 profile must remain excluded from a sequence-identified recommended set until this is resolved. Likewise, SCoT-25 should be described as listed but untested in the supplied gel images. The unusual concentration labels in the SCoT mixture and the missing within-cycle extension duration also require verification from the experimental record before the protocol is reproduced or submitted as fully specified. The second priority is to link P1-P4 unambiguously with specimen identifiers, collection province, cultivar, isolation date, and species-confirmation evidence. The positive PEF/PER record should be connected to each actual gel lane; representative ambiguous isolates should receive an independent sequence-based taxonomic check. DNA quality and input should be normalised across samples. At least two independently prepared PCRs on separate days should then be performed for each shortlisted primer, followed by electrophoresis and imaging under matched conditions. A faint, saturated, or discordant band should never be converted into a polymorphic locus on the basis of one image. Only after a repeatable set is established should blinded readers generate a documented 0/1 presence-absence matrix, agreeing on a band size window, minimum intensity threshold and missing-data rule before viewing sample origins. Primer-level total and polymorphic band counts and a transparent measure of resolving capacity may then be calculated. Inferences about geographic structure require a substantially larger collection with balanced sampling by region and appropriate statistical analysis; four lanes cannot support reliable province-specific diversity estimates. If association with patulin, virulence, or fungicide sensitivity is desired, these traits must be measured separately in the same individually identified isolates.

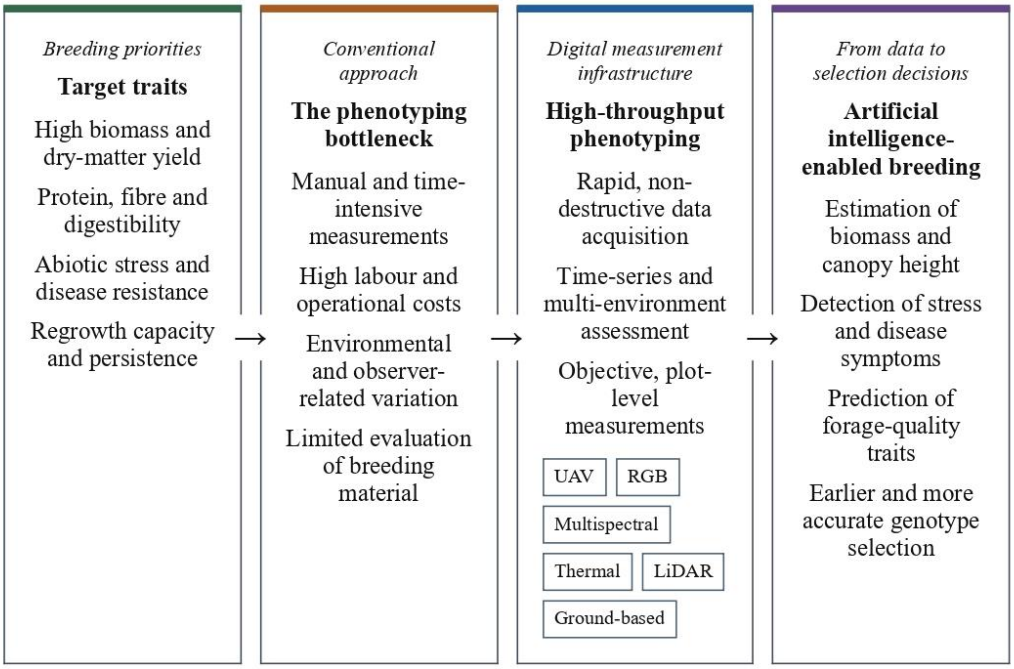
ÖZET
Yem bitkileri, hayvansal üretimin sürdürülebilirliği, yüksek kaliteli kaba yemin güvenilir bir şekilde temini ve tarımsal ekosistemlerin korunması açısından önemli bir rol oynamaktadır. Bununla birlikte, geleneksel yöntemler kullanılarak yonca, fiğ, korunga, üçgül ve çeşitli yemlik buğdaygil türlerinde biyokütle verimi, yem besin değeri, çevresel stres toleransı ve biçim sonrası yeniden büyüme kapasitesi gibi karmaşık fenotipik özelliklerin kapsamlı bir şekilde değerlendirilmesi önemli bir fenotipleme engeli oluşturmaktadır. İnsansız hava araçları, farklı kamera sistemleri (RGB, multispektral, hiperspektral, termal), LiDAR ve yer sensörlerini birleştiren yüksek verimli fenotipleme, çok sayıda genotipin hızlı, tahribatsız ve standart biçimde incelenmesine olanak tanır. Ayrıca, yapay zekâ ve ileri makine öğrenimi teknikleri bu teknolojik platformlar tarafından üretilen yüksek boyutlu verilerin etkin biçimde analiz edilmesi, biyokütle ve kalite özelliklerinin tahmin edilmesi, erken stres sinyallerinin hızla tespit edilmesi ve üstün genotiplerin hassas bir şekilde seçilmesi için yeni olanaklar sunmaktadır. Bu çalışma, temel sensör teknolojilerini, veri işleme tekniklerini, yem bitkisi çeşitlerindeki tarla uygulamalarını ve arazi kısıtlamalarını dikkate alarak, yapay zekâ destekli yüksek verimli fenotiplemenin günümüz yem bitkileri ıslahındaki rolünü kapsamlı bir şekilde değerlendirmektedir. Nitekim fenotipik, genomik ve çevresel parametrelerin entegre edilmesi, seçim hassasiyetini artırarak iklim koşullarına adaptasyonu yüksek kaliteli çeşitlerin ıslah sürecini belirgin şekilde kısaltmaktadır.
Anahtar kelimeler: Yapay zeka, İklim değişikliğine dayanıklılık, Yem bitkileri ıslahı, Yüksek verimli fenotipleme



ABSTRACT
Forage crops play an essential role in the sustainability of animal agriculture, the reliable supply of high-quality forage, and the enduring health of agricultural ecosystems. Nevertheless, thoroughly evaluating complex phenotypic traits such as biomass yield, forage nutritional value, environmental stress tolerance, and post-harvest regrowth capacity in species such as alfalfa, vetch, sainfoin, clover, and assorted forage grasses using conventional methods remains a major phenotyping challenge. High-throughput phenotyping enables rapid, non-invasive, and highly uniform assessment of numerous genotypes by systematically integrating uncrewed aerial vehicles, sophisticated RGB, multispectral, hyperspectral, and thermal imaging systems, LiDAR technology, and terrestrial sensors. Moreover, artificial intelligence and advanced machine learning techniques offer new opportunities to efficiently analyse the vast, high-dimensional data generated by these platforms, predict biomass and quality traits, rapidly detect early stress signals, and precisely select superior genotypes. This study comprehensively evaluates the role of artificial intelligence-augmented high-throughput phenotyping in contemporary forage crop breeding, considering key sensor technologies, data processing techniques, field applications in forage varieties, and notable operational limitations. In conclusion, integrating phenotypic, genomic, and environmental data can greatly improve selection accuracy, accelerating the development and market introduction of climate-resilient, high-quality forage crops.
Keywords: Artificial intelligence, Climate resilience, Forage crop breeding, High-throughput phenotyping.

INTRODUCTION

Forage crops are an essential resource for satisfying the energy, protein, and structural carbohydrate demands of ruminants, thereby supporting the economic sustainability of livestock production (Li and Brummer, 2012). Plants such as alfalfa, vetch, sainfoin, and clover are notable for their exceptional roughage yield, attributed to their increased protein concentration (Annicchiarico, 2015). These species can reduce the demand for mineral nitrogen fertilisers by supplying biological nitrogen inputs through symbiotic nitrogen fixation (Peoples et al., 2009). In addition, the root systems of perennial forage plants provide substantial advantages in soil organic carbon, aggregate stability, and erosion resistance (Lemaire et al., 2014).

In forage crop cultivation, the primary goals of dry matter and biomass output influence total roughage generation (Li and Brummer, 2012). At the same time, feed nutritional quality and resulting animal performance are governed by crude protein, neutral detergent fibre, acid detergent fibre, lignin, and digestibility (Jung and Allen, 1995). The main variables hindering yield and sustainability in forage crops are drought, heat, cold stress, as well as diseases and pests (Annicchiarico, 2015). When selecting better genotypes in perennial species, it is essential to concurrently evaluate post-harvest regrowth, winter hardiness, and long-term persistence (Annicchiarico, 2015; Li and Brummer, 2012).

Figure 1. Conceptual framework of artificial intelligence-assisted high-throughput phenotyping in forage crop breeding

Evaluating these attributes using standard methodologies requires extensive labour, time, and financial resources in experiments with many plots and genotypes (Furbank and Tester, 2011). Visual scoring is vulnerable to observer bias, which can lead to subjective errors in assessing sickness or stress (Cobb et al., 2013). Furthermore, because growth phases and environmental variables strongly affect plant phenotypes, a single evaluation point may not capture variability in genotype performance (Araus and Cairns, 2014). Thus, phenotyping is identified as a primary hindrance in current plant breeding practices (Furbank and Tester, 2011). Figure 1 illustrates the conceptual transition from target breeding traits and conventional bottlenecks to artificial intelligence-assisted high-throughput phenotyping.

HIGH THROUGHPUT PHENOTYPING AND SENSOR TECHNOLOGIES

The Scope of High-Throughput Phenotyping

High-throughput phenotyping (HTP) refers to the rapid, non-invasive, and consistent evaluation of numerous plants or plots using imaging, automation, and sensor technologies (Yang et al., 2020). A primary benefit is that it allows repeated assessment of the same genotypes at different developmental

stages. As a result, researchers can examine both ultimate yield and dynamic characteristics, including growth rate, stress response, and post-harvest regeneration (Tardieu et al., 2017). HTP aims to improve the efficiency and accuracy of selection by producing objective, high-resolution phenotypic data, especially in extensive breeding populations (Furbank and Tester, 2011; Yang et al., 2020).

Platforms, Sensors, and Measurable Traits

Phenotyping platforms are generally classified into terrestrial and airborne systems. Unmanned aerial vehicles (UAVs) offer higher spatial resolution and extensive temporal coverage across vast field experiments, enabling rapid observation of entire canopy dynamics (Xie and Yang, 2020). In contrast, terrestrial phenotyping systems operate closer to the canopy, providing detailed structural and physiological information with less atmospheric disruption (Jin et al., 2020). Table 1 summarises the primary sensing platforms, the key traits they evaluate, and their prospective applications in forage crop breeding.

Table 1. Application areas of key platforms and sensors used in high-throughput phenotyping for forage crop breeding

Technology	**Measurable Traits**	**Potential Applications in Forage Crops**
RGB Camera	Canopy cover, colour, area, height-derived structural traits (Volpato et al., 2021)	Biomass and vegetation estimation (Herzig, 2021; Wang et al., 2024)
Multispectral	NDVI, NDRE, GNDVI, chlorophyll-related vegetation indices (Hassan et al., 2019; Fu et al., 2020)	Stress and growth monitoring (Hassan et al., 2019)
Hyperspectral	Spectral signatures, pigments, nitrogen, biochemical traits (Ge et al., 2019)	Estimation of forage quality parameters (Ge et al., 2019)
Thermal Camera	Leaf and canopy temperature (Ji et al., 2026; Deery et al., 2016)	Drought and water stress identification (Araus and Cairns, 2014; Deery et al., 2016)
LiDAR	Plant height, canopy volume, 3D structural architecture (Xie and Yang, 2020)	Biomass and morphological analysis (Xie and Yang, 2020)
UAV / Drone	Rapid, frequent, high resolution spatial data over large areas (Xie and Yang, 2020; Duan et al., 2017)	Genotype comparison in field trials (Araus and Cairns, 2014; Ge et al., 2019)
Ground-Based Sensors	Fine-scale physiological and structural data at proximity (White et al., 2012)	Detailed plot-level evaluation (White et al., 2012; Deery et al., 2016)

RGB imagery can assess plant height by analysing canopy cover, colour, texture, and three-dimensional surface models (Volpato et al., 2021). Multispectral sensors support assessment of plant vitality, chlorophyll condition, and growth-related characteristics through indices such as NDVI and NDRE (Hassan et al., 2019). Thermal imaging provides essential information on plant hydration and stress responses by assessing canopy temperatures (Araus and Cairns, 2014). LiDAR is utilized to quantitatively assess plant height, canopy volume, and three-dimensional structure (Xie and Yang, 2020). Combining structural and spectral data from multiple sensor types markedly improves dry matter yield estimates compared with relying on individual sensor sources (Pranga et al., 2021).

THE ROLE OF ARTIFICIAL INTELLIGENCE AND MACHINE LEARNING

Analysis of Large Phenotypic Data

HTP platforms produce substantial data from RGB, multispectral, hyperspectral, thermal, and LiDAR technologies (Xie and Yang, 2020; Yang et al., 2020). Image processing and machine learning techniques enable automatic retrieval of phenotypic variables, including vegetation cover, canopy volume, colour and texture characteristics, vegetation indices, and plant height, from these unprocessed images (Singh et al., 2016). This automation reduces dependence on manual measurements, facilitating assessment of more genotypes over the same trial duration (Furbank and Tester, 2011).

Field data may be affected by variables including varying light conditions, shade, wind, soil background, flight elevation, and sensor calibration (Xie and Yang, 2020). As a result, implement image segmentation, radiometric correction, outlier identification, data filtration, and standardisation procedures before data analysis (Yang et al., 2020). Appropriate calibration methods and experimental frameworks significantly influence the ability to compare data gathered from different time intervals or settings (Araus and Cairns, 2014).

Core Artificial Intelligence Methods

Regression techniques forecast continuous variables such as biomass, dry matter production, plant height, and other quality characteristics. These models often use spectral indices, RGB-based vegetation metrics, and canopy height as inputs (Wang et al., 2024). In alfalfa breeding experiments, UAV-derived RGB and multispectral imagery have been shown to assess plant height and aboveground biomass effectively (Wang et al., 2024).

Tree-based methods like Random Forest and XGBoost deliver strong predictive performance in phenotyping datasets marked by many variables and nonlinear associations (Singh et al., 2016). In addition to their prediction abilities, these models assist in determining which factors, such as pixel counts, vegetation indices, and texture metrics, are most significant for the desired characteristics. A study on Megathyrsus maximus reported predicted accuracies above $r > 0.80$ for both green and dry matter yield using digital characteristics derived from RGB photographs alongside machine learning models (Niederauer et al., 2026).

Support Vector Machines are utilized for classification tasks in high-dimensional datasets (Singh et al., 2016). These methods enable classification of genotypes into healthy and stressed categories or assessment of stress intensity. Convolutional Neural Networks, adept at autonomously discerning colour, shape, and texture patterns from images, show strong efficacy in identifying disease symptoms, classifying weeds, and evaluating developmental stages (Singh et al., 2016). Nonetheless, the reliability of deep learning models depends on adequate labelled training data that reflects a variety of environmental conditions (Yang et al., 2020).

Time series analysis enables examination of growth patterns by repeatedly assessing the same genotypes on several dates (Tardieu et al., 2017). This approach is essential for evaluating characteristics that cannot be measured through isolated timepoint assessments, including growth rate, recovery after stress, post-harvest regrowth, and performance stability across seasons (Yang et al., 2020). For enduring and multiple-harvest forage species, temporal phenotyping enables selection of genotypes based not only on yield capacity but also on reliable performance across multiple developmental phases (Wang et al., 2024).

APPLICATIONS IN FORAGE CROPS

The estimation of biomass and plant height is one of the most advanced application domains of high-throughput phenotyping (HTP) in forage crops. UAV-based structural and spectral data fusion was more accurate than standalone data sources in predicting dry matter yield in perennial ryegrass (Pranga et al., 2021). Different sensors have different advantages for the target traits in alfalfa. For example, multispectral data is helpful for biomass estimation, while RGB data is very good for plant height measurement (Wang et al., 2024).

HTP can also be used for early detection of stress response. Although multispectral indices are valuable in providing information on plant vigor and growth status, thermal imaging can serve as early warning indicators for water stress based on the changes in canopy temperature (Araus and Cairns, 2014; Hassan

et al., 2019). These datasets provide direct field-based phenotypic evidence to support the selection of drought tolerant genotypes.

Hyperspectral data can capture spectral signals of pigments, nitrogen status and some biochemical components, so they are of forage quality (Xie and Yang, 2020). However, the calibration of quality prediction models with laboratory analyzes is rigorous for different species, harvest regimes and environmental conditions. Hence, HTP should be seen as a complementary tool to support the preliminary screening and targeted sampling of large breeding populations rather than as a complete replacement for wet laboratory chemistry.

INCORPORATION WITH GENOMIC SELECTION AND CONSTRAINTS

Secondary characteristics extracted from high-throughput phenotyping could improve the predictive accuracy of complex traits in genomic selection frameworks (Tardieu et al., 2017). Temporal phenotype measurements would allow more detailed analysis of genotype × environment interactions (Yang et al., 2020). This approach sets the stage for data-driven breeding strategies that integrate genomic, phenotypic, and environmental data.

However, HTP applications have several limitations, including high sensor costs, data storage constraints, calibration requirements, experimental design challenges, limited model applicability across contexts, and the need for specialist personnel (Xie and Yang, 2020; Yang et al., 2020). Predictive models should be validated on independent datasets, across different years and conditions, not only on the trials for which they were developed. Successful implementation thus requires the collaboration of plant breeders, remote sensing experts, and statisticians and data analysts.

CONCLUSION

Artificial intelligence-assisted high-throughput phenotyping can facilitate tackling the challenges of manual phenotyping in forage crop breeding. Sensor technologies allow for fast and reproducible monitoring of biomass, plant height, canopy structure, stress responses and specific quality-related traits. These multidimensional datasets are converted through machine learning methods into usable selection decisions, enabling the earlier and more objective identification of superior genotypes. However, rigorous model calibration and multi-environmental validation are still needed for reliable deployment of these technologies. Integration of high-throughput phenotyping, genomic selection and environmental data layers in a seamless manner will accelerate the development of high-yielding, high-quality and climate-resilient forage cultivars in the future.

ÖZET

Yem bitkileri, ruminant üretiminin temelini oluşturmakla birlikte, bu türlerin ıslahı tür içi genomik varyasyonun yetersiz temsil edilmesi nedeniyle sınırlanmaktadır. Tek bir referans genom, yüksek heterozigotluk, yabancı tozlaşma, poliploitlik ve yoğun tekrarlayan DNA içeriği taşıyan yem bitkisi türlerinde genomik çeşitliliği yeterince yansıtamamaktadır. Bu derleme, genetik çeşitliliğin araştırılması ve genomik bilginin yem bitkileri ıslahına aktarılması açısından doğrusal referans genomlardan pangenomlara geçişi değerlendirmektedir. Uzun okuma dizileme teknolojileri, haplotip çözümlemeli montajlar ve graf tabanlı genom temsilleri, geleneksel kısa okuma eşleştirme yaklaşımlarında sıklıkla gözden kaçan yapısal varyasyonların, kopya sayısı varyasyonlarının ve gen varlığı-yokluğu varyasyonlarının belirlenmesine olanak sağlamaktadır. Yonca, kırmızı üçgül, ak üçgül ve ilişkili buğdaygil sistemlerinden elde edilen bulgular, bu varyasyonların stres adaptasyonu, hastalık yanıtı ve agronomik performans açısından biyolojik önemini ortaya koymaktadır. Çalışmada, temsil gücü yüksek aksessiyonların seçimi, de novo montaj, fazlama, anotasyon, graf oluşturma ve varyant genotiplemeyi kapsayan yem bitkisi pangenomlarının oluşturulmasına yönelik uygulamalı iş akışları ele alınmaktadır. Ayrıca pangenom çapında ilişkilendirme çalışmaları, genomik seleksiyon ve pangenom destekli çekirdek koleksiyon geliştirme yaklaşımları incelenmektedir. Hesaplama gereksinimleri, iş akışlarının standardizasyonu ve yüksek kaliteli yem bitkisi genom montajlarının sınırlı sayıda olması önemli darboğazlar olmaya devam etse de, pangenomik yaklaşım adaptif alellerin keşfedilmesini ve ıslah programlarında kullanılmasını önemli ölçüde geliştirme potansiyeline sahiptir. Başlıca yem baklagilleri ve buğdaygiller için koordineli referans pangenom girişimleri, iklim koşullarına dayanıklı, verimli ve besin değeri yüksek çeşitlerin geliştirilmesi açısından stratejik önem taşımaktadır.

ABSTRACT

Forage crops underpin ruminant production, yet their improvement is constrained by the incomplete representation of within species genomic variation. A single reference genome is particularly insufficient for forage species because many are highly heterozygous, outcrossing and polyploid, and contain extensive repetitive DNA. This review evaluates the transition from linear reference genomes to pangenomes as a framework for investigating genetic diversity and translating genomic information into forage crop breeding. Long-read sequencing, haplotype-resolved assembly, and graph-based representations now enable recovery of structural variants, copy number variants, and gene presence-absence variation that conventional short-read mapping often misses. Evidence from alfalfa, red clover, white clover and related grass systems illustrates the biological relevance of these variants for stress adaptation, disease response and agronomic performance. We discuss practical workflows for constructing forage pangenomes, including selection of representative accessions, de novo assembly, phasing, annotation, graph construction and variant genotyping. We also examine pangenome-wide association studies, genomic selection and pangenome-informed core collection development. Although computational requirements, pipeline standardisation, and the limited number of high-quality forage assemblies remain important bottlenecks, pangenomics can substantially improve the discovery and deployment of adaptive alleles. Coordinated reference pangenome initiatives for major forage legumes

and grasses will therefore be strategically important for breeding climate resilient, productive and nutritionally valuable cultivars.

Keywords: alfalfa, forage breeding, genetic diversity, graph genome, pangenome, structural variation

INTRODUCTION

Genetic diversity is the basis of crop adaptation and sustained genetic improvement. In forage crops, this diversity must support several breeding objectives simultaneously, including biomass yield, persistence, nutritive value, disease resistance and tolerance to increasingly variable temperature and water regimes. The genomic architecture underlying these traits is difficult to capture in a single sequence assembly. Alfalfa (*Medicago sativa* L.), for example, is an autotetraploid, predominantly outcrossing forage legume in which four homologous chromosomes contribute to each chromosome group. Comparable assembly challenges are documented for autotetraploid alfalfa (Chen et al., 2020). Highly heterozygous red clover requires long-read chromosome-scale assembly (Bickhart et al., 2022). Haplotype resolved white clover resources show the additional complexity created by multiple subgenomes (Santangelo et al., 2023).

The reference genome paradigm has enabled marker discovery, genome wide association studies and genomic prediction. Nevertheless, a linear sequence constructed from one genotype necessarily excludes sequences present only in other genotypes. Reads originating from divergent or absent regions can map poorly, be assigned incorrectly or remain unmapped. This phenomenon is commonly described as reference bias (Coletta et al., 2021). It can reduce the detection of insertions, deletions, copy number variants and gene presence absence variants. Graph based pangenomes provide a way to represent this missing diversity (Wang et al., 2022).

A pangenome represents the collective genomic content of a species or breeding population, not the sequence of a single individual. By combining shared sequences with alternative alleles and access-specific sequences, it provides a more complete description of diversity. The aim of this review is to explain why pangenomic approaches are particularly important for forage crops, to summarize the technologies and computational strategies used in their development, and to discuss their integration into diversity analysis and breeding.

GENOMIC COMPLEXITY OF FORAGE CROPS

Polyploidy and Heterozygosity

Polyploidy is widespread among forage species and has important consequences for genome analysis. Autopolyploids such as cultivated alfalfa contain multiple related homologous chromosomes, whereas allopolyploids such as white clover contain distinguishable ancestral subgenomes. Both systems require accurate separation of homologous or homeologous sequence during assembly. If alternative haplotypes are collapsed into a consensus sequence, genuinely distinct alleles and structural variants can be lost. Chen et al. (2020) addressed this challenge by producing an allele aware chromosome level assembly for cultivated autotetraploid alfalfa, demonstrating the feasibility and value of resolving 32 allelic chromosomes. However, a single high-quality assembly does not represent the species as a whole.

High heterozygosity further increases assembly difficulty. Outcrossing forage species maintain diverse haplotypes that are valuable for adaptation but difficult to resolve with short reads. In red clover, a chromosome-scale assembly substantially improved contiguity relative to older fragmented resources and illustrated the importance of long-read sequencing for highly heterozygous allogamous crops (Bickhart et al., 2022). Haplotype resolved white clover resources likewise allow both allelic and subgenomic diversity to be examined more explicitly (Santangelo et al., 2023).

Repetitive DNA and Structural Variation

Transposable elements, consecutive repeats, and duplicated gene families add a second layer of complexity. Short reads often cannot cover repeats, leading to fragmented contigs and ambiguous placement of duplicated sequences. Long-read sequencing supports more complete plant genome assemblies by scanning repetitive intervals (Michael and VanBuren, 2020). Polyploid genomes still require significant coverage and careful phasing (Pucker et al., 2022). Structural variants, traditionally defined as changes larger than approximately 50 bp, include deletions, insertions, inversions, translocations, and copy number alterations. These variants can alter coding dose, promoter context, and

gene regulation, and their contribution to phenotypic diversity may be underestimated when only SNPs are analyzed.

LIMITATIONS OF SINGLE REFERENCE GENOMES

A linear reference offers one coordinate system and one set of alleles at each locus. This representation is efficient for routine alignment but becomes restrictive when a species contains extensive sequence content diversity. Alternative segments cannot be represented at the same coordinate without either excluding them or treating them as non reference sequence. Consequently, mapping based analyses may favor the genotype from which the reference was assembled and may undercall variants in genetically distant landraces, wild relatives or elite breeding material (Coletta et al., 2021).

The biological cost of this omission is clear in Medicago truncatula, a model forage legume. Comparison of multiple de novo assemblies identified substantial novel sequence and extensive structural differences among accessions. many variable gene families were associated with biotic interactions and stress related functions (Zhou et al., 2017). Although M. truncatula is not cultivated alfalfa, it provides a strong proof of concept for the genus: gene content is not fixed within a species, and a single reference cannot adequately characterize all diversity available to breeding. In white clover, copy number differences at loci involved in cyanogenesis have also been linked to environmental adaptation, illustrating how structural variation can affect ecologically important phenotypes (Kuo et al., 2024).

Single reference mapping also limits population genetic interpretation. Genetic distances and diversity statistics based only on callable SNPs exclude unrepresented sequence, whereas presence absence variation may reveal population structure and adaptive differentiation not visible in a SNP only analysis. This is especially relevant to geographically diverse germplasm collections, where local adaptation may be encoded partly by genomic segments absent from a modern reference cultivar.

THE PANGENOME CONCEPT AND GRAPH REPRESENTATION

Core and Accessory Genomic Components

Pangenomes are often described in terms of core and accessory components. Core genes or sequences occur in all sampled genomes, whereas accessory sequences occur in a subset of accessions. Accessory components may be further classified as shell sequences, present at intermediate frequency, and cloud sequences, which are rare or accession-specific. These categories are analytical descriptions rather than fixed biological classes because their estimated size depends on sampling breadth and annotation quality (Gautreau et al., 2020). Crop pangenome resources also emphasize that category estimates change with the assemblies included in the analysis (Naithani et al., 2023). In crop species, accessory genes are frequently enriched for functions related to environmental response, pathogen interaction and specialized metabolism.

From Linear References to Genome Graphs

A graph-based pangenome represents genomic sequence as nodes connected by edges. Each accession or haplotype is stored as a path through the graph. Shared segments are represented once, while alternative alleles or structural variants are represented as branching paths. This avoids forcing all diversity into one linear sequence and enables reads to align against both reference and non-reference alleles. The variation graph toolkit supports read mapping against alternate genomic paths (Garrison et al., 2018). Minigraph enables the construction of reference pangenome graphs (Li et al., 2020). Graph genome frameworks are increasingly used for plant genomic analysis (Wang et al., 2022).

For forage crops, graph representation is attractive because it can retain multiple allelic paths and accession-specific insertions. The approach does not eliminate the need for high quality assemblies. rather, it makes those assemblies more useful by combining them into a shared, navigable structure. A practical pangenome can therefore serve as a population-aware reference for resequencing, transcriptomics and trait mapping. The conceptual contrast between a single linear reference and a graph based pangenome is illustrated in Figure 1.

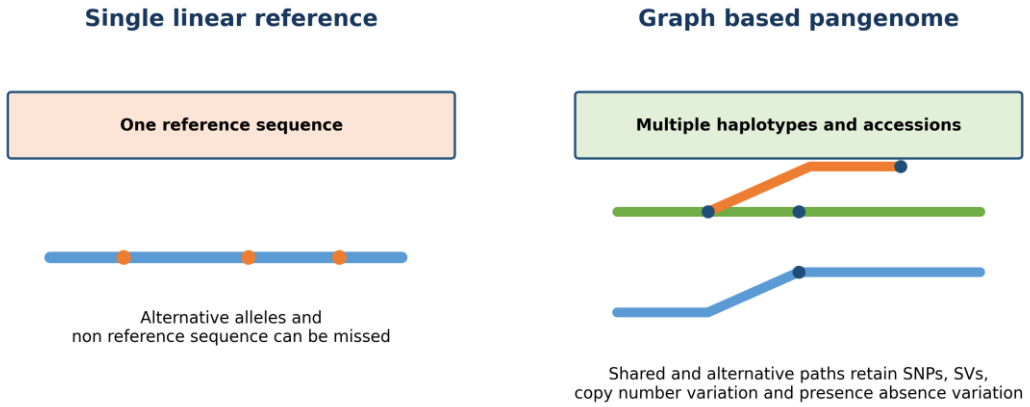

Figure 1. Conceptual comparison of a single linear reference genome and a graph based pangenome.

SEQUENCING TECHNOLOGIES AND PANGENOME CONSTRUCTION

Long Reads and Complementary Data

Short read platforms remain useful for population-scale genotyping because they are accurate and cost-effective. However, they are rarely sufficient on their own to assemble highly repetitive and heterozygous polyploid genomes. PacBio HiFi reads combine long read length with high per-base accuracy, whereas Oxford Nanopore sequencing can generate very long reads that bridge complex repeats and structural variants. Hi-C and optical mapping can provide complementary long-range information for chromosome scaffolding (Michael and VanBuren, 2020). Gametic data can further improve haplotype resolution in autopolyploids (Zhang et al., 2024).

A Practical Forage Pangenome Workflow

Construction begins with purposeful sampling. A founding panel should include elite cultivars, landraces, geographically distinct accessions, material from contrasting environments and, where compatible, wild relatives. The number of assemblies should be sufficient to capture major gene content and structural diversity, but the panel should also remain tractable for high-quality sequencing. Each selected accession is assembled de novo, ideally with haplotype resolution. Assemblies are then assessed for contiguity, completeness, duplicated gene content and correct chromosome assignment before pangenome alignment or graph construction.

The next stages are structural variant discovery, gene annotation harmonization and graph generation. Annotation should use comparable evidence across assemblies to reduce false presence/absence calls caused by unequal gene prediction. The final graph can map short reads from a broader diversity panel, genotype SNPs and structural variants, and estimate the distribution of accessory genes. The major stages and their sequence are summarized in Figure 2. Because no single pipeline is universally optimal, benchmarking with known variants and simulated reads is advisable. Transparent reporting of coverage, phasing quality, graph statistics and callable regions is essential for reproducibility.

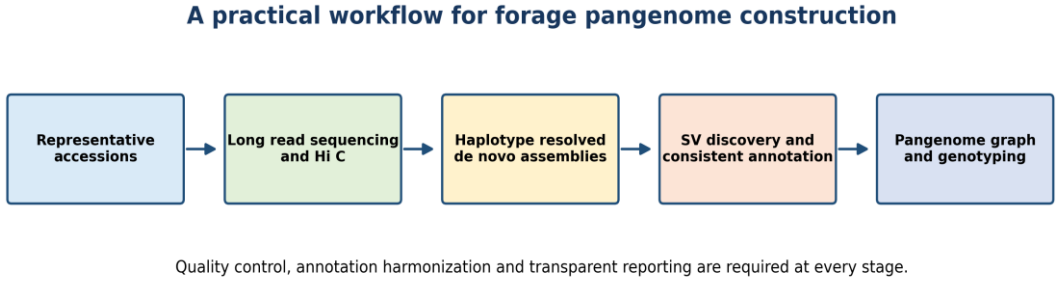

Figure 2. Suggested workflow for constructing a forage crop pangenome.

APPLICATIONS IN GENETIC DIVERSITY AND TRAIT MAPPING

Structural and Functional Diversity

Pangenomes expand diversity analysis beyond SNP frequencies. Presence-absence variants can be encoded as binary markers, copy number variants can be quantified, and complex alleles can be evaluated in their actual haplotypic context. This is particularly valuable for resistance gene clusters and genes associated with secondary metabolism, which often reside in dynamic regions rich in repeats and duplications. A melon graph pangenome increased genotyping density and connected structural variants with fungal resistance (Vaughn et al., 2022).

For forage crops, these approaches can improve the characterization of collections currently described primarily by morphological descriptors or conventional molecular markers. A pangenome-informed diversity panel could distinguish broadly shared genomic backgrounds from rare, potentially adaptive variation in gene content. It can also improve accession selection for a core collection by combining allele frequencies, structural diversity, geographic origin, and phenotypic performance.

Pangenome-wide Association Studies

Conventional GWAS tests SNPs or small indels against phenotypic variation. Pangenome-wide association studies extend the variant set to include structural variants, gene presence/absence states and graph paths. This makes it possible to test whether a gene is present, absent or dosage variable rather than assuming all relevant variation is a nearby SNP in the reference genome. A tomato graph pangenome captured previously missing variation and improved the resolution of breeding relevant associations (Zhou et al., 2022).

The same logic applies to forage traits such as regrowth, winter survival, drought tolerance, digestibility, lignin concentration, and pathogen response. Robust Pan GWAS requires accurate phenotyping across environments, appropriate adjustment for kinship and population structure, and independent validation. Structural variants can be less frequent than SNPs, so rare-variant burden tests, haplotype-based methods, and biologically informed candidate-region analyses may complement single-variant tests.

Climate Resilience and Adaptive Variation

Forage production increasingly depends on varieties that remain productive under drought, heat, cold, salinity and new disease pressures. Local germplasm and wild relatives are important reservoirs of adaptive diversity, but some useful segments may be poorly represented in a cultivar reference. By preserving non-reference sequences, pangenomes can identify candidate genes and genomic regions whose distribution corresponds to environmental gradients or stress-associated phenotypes. They can also clarify whether adaptation involves SNP substitution, gene gain or loss, copy number change, altered gene order or interactions among these mechanisms.

INTEGRATION WITH FORAGE CROP BREEDING

Genomic Selection and Allele Dosage

Genomic selection predicts breeding value from genome wide markers and is particularly useful for complex traits. In polyploid forage crops, prediction accuracy is influenced by allele dosage, linkage disequilibrium, relatedness between training and selection populations, and phenotyping quality. Pangenome-derived markers can enrich prediction models by adding structural and gene content variation to conventional SNP datasets. This does not guarantee improvement in every population. benefit must be evaluated through cross-validation and independent breeding cycles. Genomic selection in forage grasses depends on marker information, phenotyping and relationships between training and selection populations (Resende et al., 2021). Pangenome derived markers may reduce reference bias when they represent causal or tightly linked variation.

Allele aware pangenomes may also help disentangle dosage and haplotype effects in autotetraploid alfalfa. Instead of treating a locus as a simplified biallelic SNP, a graph can retain larger haplotypes and alternate structural forms. Such information could support the selection of favourable haplotype combinations while maintaining genetic diversity needed for long-term improvement.

Germplasm Utilization and Pre-breeding

Gene banks contain a large but incompletely characterized reservoir of forage diversity. Pangenomic information can support pre-breeding by identifying accessions that contribute unique alleles or accessory genes without unnecessarily duplicating already represented genomic content. A pangenome-informed core collection would not simply maximise SNP distance. it would seek to preserve common haplotypes, rare structural variants, adaptive gene content and geographic representation. This strategy could make phenotyping and crossing programs more efficient while retaining the broad diversity required for future climate scenarios. Figure 3 summarizes how pangenomic information can support Pan GWAS, genomic selection and core collection development in forage breeding.

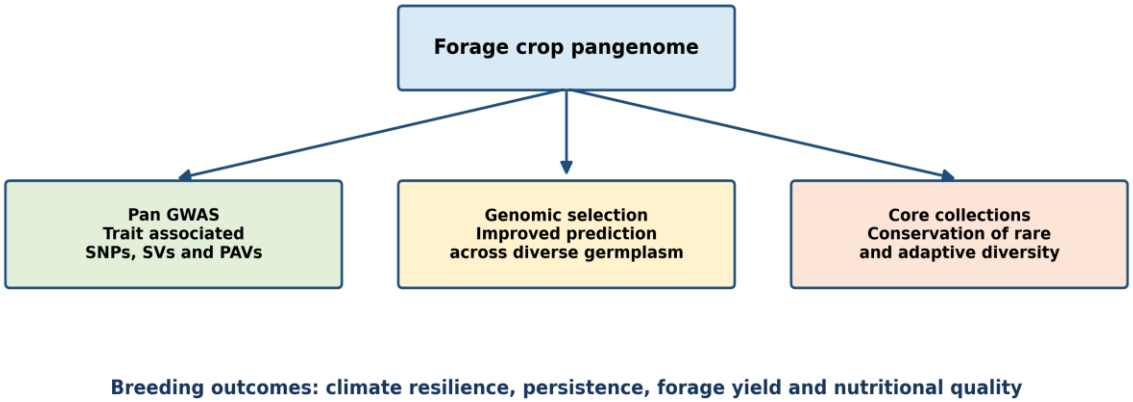

Figure 3. Major pathways through which pangenomic information can support forage crop improvement.

CHALLENGES AND FUTURE PERSPECTIVES

The main constraints are cost, computing infrastructure, and standardization. High-quality de novo compilations and haplotype phasing remain expensive, especially in polyploid species. While graphs generated from numerous compilations can be challenging to store, visualize, and query, pangenome-aware mapping and genotyping require specialized software and careful quality control. In highly heterozygous and polyploid forage plants, the choice of graph representation and sequencing strategy can affect the recovery of structural variation and alternative haplotypes (Kaur et al., 2024; Li et al., 2020). Therefore, standardized data formats, widely accessible workflows, and publicly available repositories are crucial for adoption beyond a small number of well-sourced projects.

A second challenge is sampling design. A pangenome cannot represent all diversity unless the founder genomes capture core breeding pools, ecogeographic groups, and wild or semi-wild material. Inclusion of diverse samples is crucial because a limited or genetically narrow panel may underestimate accessory genome and structural variation within a species (Coletta et al., 2021; Gautreau et al., 2020). Conversely, inclusion of low-quality compilations or inconsistently annotated genomes can lead to artificial variations. Future forage plant pangenomes should be created by international consortia incorporating sequencing, common annotation standards, robust phenotyping, and open data sharing. Coordinated resources for Medicago sativa, Trifolium species, Lolium species, meadow grass, and sainfoin will provide a basis for comparable diversity and breeding studies.

Integration with transcriptomics, epigenomics, metabolomics, and high-throughput phenotyping is the next major opportunity. While a pangenome identifies genomic alternatives, multiple omics data can determine which alternatives are expressed, regulated, or associated with beneficial physiological responses. This integration is particularly important for determining the functional significance of structural variants, copy number variation, and accessory gene content that may contribute to stress adaptation and agricultural performance (Zhou et al., 2017; Kuo et al., 2024). Combining these layers with multiple environmental field trials will enable the transition from descriptive catalogs of variation to validated, viable breeding targets.

CONCLUSION

Pangenomics provides a more realistic representation of forage crop diversity than a single linear reference genome. By recovering structural variants, copy number differences and gene presence-absence variation, it can reveal genomic components that influence adaptation and agronomic performance but are often missed by SNP-centered analyses. Long-read sequencing, haplotype-resolved assembly and graph-based representation are now sufficiently mature to support targeted pangenome initiatives in major forage legumes and grasses. Their greatest value will be realised when pangenomic data are connected to rigorous multi-environment phenotyping, genomic selection and germplasm management decisions. Developing shared reference pangenomes for forage crops is therefore a strategic route toward productive, persistent and climate-resilient cultivars.

ABSTRACT
Maintaining high germination performance during post-processing and storage is essential to preserve seed quality and ensure successful stand establishment in alfalfa. This study aimed to determine how seed coating, storage, and transfer processes affect the germination performance of different alfalfa cultivars. Uncoated and coated seeds of five cultivars, Bilensoy, Blue Ace, Bolton, Icon, and Sunter, were evaluated before storage, after storage, and following the transfer process. Germination rate and germination percentage were used as the main indicators of physiological seed performance. The results showed that seed coating, cultivar, and their interactions with storage and transfer stages significantly influenced germination performance. Overall, coating increased the mean germination rate from 83.82% in uncoated seeds to 86.38% in coated seeds. Germination rate remained relatively stable across the evaluation stages, with mean values of 84.88% before storage, 85.20% after storage, and 85.23% after transfer. Bolton (89.21%) and Icon (88.46%) showed the highest overall germination rates, while Sunter had the lowest (80.29%). Coated Icon seeds recorded the highest germination rate (95.50%) after transfer. Similarly, coating increased mean germination from 86.40% to 89.42%, an improvement of about 3.50%. Germination percentage remained stable across storage stages, ranging from 87.60 to 88.08%. Icon (91.38%) and Bolton (90.71%) showed the highest germination percentages, whereas Sunter had the lowest value (83.50%). Coated Icon seeds after transfer showed the highest germination percentage (98.00%). Notably, germination percentage declined from 87.25% to 85.25% in uncoated seeds from pre-storage to post-transfer, whereas it increased from 88.85% to 89.95% in coated seeds. These findings show that seed coating can help maintain and improve alfalfa seed germination during storage and transfer; however, the magnitude of this response is strongly cultivar-dependent. Therefore, genotype-specific optimization of coating and storage protocols may provide an effective strategy for preserving the physiological quality of commercial alfalfa seeds.
Keywords: Germination Percentage, Germination Rate, Seed Coating, Storage, Seed Quality.

INTRODUCTION
Alfalfa (*Medicago sativa* L.) is recognized as one of the most important forage crops worldwide because of its high forage quality, perennial growth habit, broad adaptability, and contribution to agricultural production systems through symbiotic nitrogen fixation (Rocha et al., 2019; Zhang et al., 2022). The establishment of a persistent, uniform, and highly productive stand in alfalfa cultivation largely depends on achieving rapid and uniform germination following sowing. Therefore, commercial seed quality assessment should consider not only final germination percentage but also traits reflecting seed vigor, such as germination speed, emergence speed, and final emergence percentage (Rajjou et al., 2012; Afzal et al., 2020). Germination is a critical developmental stage that begins with water uptake by the dry seed and culminates in the emergence of the embryonic axis through the seed-covering structures, involving interconnected physiological and biochemical processes such as metabolic activation, cellular repair, mobilization of stored reserves, and embryo growth (Rajjou et al., 2012). Consequently, any delay or irregularity during this process may impair uniform stand establishment under field conditions, making the maintenance of germination performance a fundamental quality criterion in alfalfa seed production. One major factor determining germination behavior in alfalfa seeds is physical dormancy, commonly referred to as hardseededness, which is associated with the impermeability of the seed coat to water. Although the embryo remains viable in hard seeds, preventing or delaying water uptake may restrict

germination initiation; therefore, low germination percentages do not necessarily indicate a direct loss of seed viability. Differences in the anatomical and chemical structure of the seed coat have been reported to play a decisive role in water permeability and physical dormancy (Galussi et al., 2015; Li et al., 2025). Moreover, hardseededness may change during storage, and some initially water-impermeable but viable seeds may become permeable over time, thereby increasing the proportion of germinable seeds (Čupić et al., 2005). Conversely, prolonged storage, particularly when temperature, relative humidity, and seed moisture content are not adequately controlled, may accelerate physiological aging, resulting in loss of membrane integrity, increased oxidative damage, and reduced cellular repair capacity (Rajjou and Debeaujon, 2008; Rajjou et al., 2012). Because many of these changes may become evident as reduced germination speed and impaired germination uniformity before a measurable loss of final viability occurs, post-storage seed quality should be evaluated using multiple germination and vigor parameters.

Seed coating technologies are increasingly used to improve the sowing performance and maintain the physiological quality of commercial seeds. Beyond modifying seed physical characteristics, coating treatments can facilitate targeted delivery of nutrients, biostimulants, plant protection products, and beneficial microorganisms directly to the seed microenvironment (Afzal et al., 2020; Paravar et al., 2023). However, the effect of coating on germination may vary depending on the coating material's physical and chemical properties, coating thickness, binder concentration, and, in particular, the coating layer's water and gas permeability. A coating layer with appropriate properties may create a favorable microenvironment around the seed and promote germination, whereas excessive mechanical resistance or low permeability may delay water uptake and coating disintegration, thereby restricting germination speed (Qiu et al., 2020; Sprey et al., 2025). Studies in different species, including alfalfa, have shown that the effects of coating treatments on germination performance may vary by formulation, application rate, environmental conditions, and genotype (Bıçakcı et al., 2018; Arslan et al., 2020; Öten and Tuzlacı, 2024). These findings indicate that the effects of seed coating on germination should not be interpreted as a uniform response but rather within the framework of genotype × coating × environment interactions.

A critical consideration in the commercial use of coated seeds is the extent to which germination performance achieved after coating can be maintained during storage and subsequent transportation/transfer processes. Because coating materials can modify seed moisture balance and water and gas exchange, coated seeds may behave differently during storage than uncoated seeds (Afzal et al., 2020; Sprey et al., 2025). Furthermore, the commercial seed supply chain involves not only storage but also subsequent transfer processes, during which fluctuations in temperature and relative humidity, together with physical stresses, may induce additional changes in seed germination performance. Nevertheless, information regarding the shelf life and post-storage physiological performance of coated seeds remains limited, and interactions among coating, storage, and subsequent handling processes require further investigation (Afzal et al., 2020; Paravar et al., 2023; Rocha et al., 2019). Therefore, evaluating coating, storage, and transfer not as independent factors but as sequential processes to which commercial seeds are exposed before sowing may provide a more comprehensive understanding of the mechanisms that maintain germination performance in alfalfa seeds.

This study comparatively evaluated the germination performance of coated and uncoated seeds from different alfalfa cultivars before storage, after storage, and after storage plus transfer. Specifically, the study aimed to determine the individual and interactive effects of cultivar, seed coating, and storage/transfer processes on germination speed, final germination percentage, emergence speed, and final emergence percentage. By comparing responses of alfalfa cultivars with different dormancy characteristics to coating and storage processes, the study also aimed to determine how well the physiological quality of coated seeds is maintained throughout commercial storage and distribution. The findings are expected to contribute to evaluating seed-coating technologies in alfalfa in terms of germination performance, identifying cultivar-specific responses, and developing management practices to maintain high physiological seed quality during storage and transfer.

MATERIALS AND METHODS

Plant Material

This study was conducted between 2024 and 2025 in the laboratories of the Ankara Seed Registration and Certification Directorate to determine changes in seed physiological quality, germination

performance, and early seedling development of uncoated and coated alfalfa (Medicago sativa L.) seeds before storage, after storage, and after storage plus transportation. Seeds of five alfalfa cultivars representing different dormancy groups, namely Bilensoy-80, Blue Ace, Bolton, Icon, and Sunter, were used as plant material. Seeds from the same seed lot of each cultivar were divided into two groups to compare coated and uncoated seeds. Seed coating was performed by ABEL Tohumculuk A.Ş. at a 1:1 ratio (w/w), corresponding to 1 kg of coating material per 1 kg of seed.

Among the cultivars used in the study, Bilensoy-80 (dormancy group 4) is adapted to the Central Anatolian and Transitional Regions and is resistant to winter conditions, drought, and lodging. Blue Ace (dormancy group 9) is characterized by a semi-erect growth habit, fine stems, a high leaf-to-stem ratio, strong seedling vigor, and adaptation to hot and dry conditions. Bolton (dormancy group 5) is characterized by high fresh and dry forage yields and high crude protein content. Icon (dormancy group 6) is characterized by high seedling vigor and a high leaf-to-stem ratio, as well as resistance to lodging, Fusarium, and Phytophthora. Sunter (dormancy group 5–7) is characterized by a strong and deep root system, rapid regrowth capacity, high forage yield potential, and tolerance to adverse winter conditions. Thus, the study was designed to comparatively evaluate the physiological responses of cultivars differing in genetic and agronomic characteristics and dormancy levels to seed coating, storage, and transportation.

Methods

Germination performance before storage

To determine pre-storage germination performance, seeds were taken from harvested plants that had not yet undergone storage or transportation. Standard germination tests were conducted in accordance with the rules of the International Seed Testing Association (ISTA) to determine the initial physiological quality of the seeds. Germination speed, final germination percentage, emergence speed, final emergence percentage, number of normal seedlings, and number of dead seeds were determined. These values served as baseline data for assessing changes after storage and transportation (ISTA, 2025).

Germination performance after Storage

To determine the effects of storage on seed physiological quality and early seedling development, the seeds were stored for approximately six months at +5 °C and 60% relative humidity. At the end of the storage period, the physiological quality characteristics of the seeds were reassessed in accordance with ISTA rules. Standard germination tests were conducted, and germination speed, final germination percentage, emergence speed, final emergence percentage, number of normal seedlings, and number of dead seeds were determined. The results were compared with the pre-storage values to assess the effects of the six-month storage period on seed physiological quality and early seedling development (ISTA, 2025).

Germination performance before storage after storage + transportation

To determine the effects of transportation following storage on seed performance, seeds stored for approximately six months at +5 °C and 60% relative humidity were subjected to a 16-h transportation period after storage. Following transportation, seed physiological quality was evaluated in accordance with ISTA rules. Standard germination tests were conducted to determine germination speed, final germination percentage, emergence speed, final emergence percentage, number of normal seedlings, and number of dead seeds. The resulting data were compared with the pre-storage and post-storage results to determine the sequential effects of storage and subsequent transportation on seed physiological quality and early seedling development (ISTA, 2025).

Statistical Analysis

The experiment data were analyzed using analysis of variance (ANOVA) in JMP statistical software. For factors and interactions found to be statistically significant by ANOVA, mean comparisons were performed using Tukey's Honestly Significant Difference (HSD) multiple comparison test available in JMP (JMP, 2023). Statistical differences were evaluated at the 5% significance level ($p < 0.05$), and differences among means were indicated by letter groupings.

RESULTS AND DISCUSSION

Germination Speed

Analysis of variance showed that coating and cultivar significantly affected germination speed in alfalfa ($p < 0.01$), whereas storage stage had no statistically significant main effect. However, significant coating × storage, cultivar × coating, cultivar × storage, and cultivar × coating × storage interactions ($p < 0.01$) showed that responses to storage and transportation varied considerably by coating status and genotype (Table 1). Based on the overall means, coating increased germination speed from 83.82% in uncoated seeds to 86.38% in coated seeds, corresponding to an increase of approximately 3.05%. Overall means across storage stages were 84.88% before storage, 85.20% after storage, and 85.23% after transportation, indicating that germination speed was largely maintained throughout storage and transportation. Nevertheless, the coating × storage interaction revealed a more distinct response pattern: germination speed in uncoated seeds decreased from 84.05% before storage to 83.10% after transportation, whereas that of coated seeds increased from 85.70% to 87.35% over the same period. These results suggest that seed coating may help maintain germination speed, particularly after storage and transportation.

Table 1. Mean squares from the analysis of variance for germination traits of alfalfa cultivars under different coating treatments and storage stages.

Source of Variation	DF	Germination Speed	Germination Percentage	Emergence Speed
Total	119

Cultivars differed in germination performance. Averaged across coating treatments and storage stages, Bolton (89.21%) and Icon (88.46%) showed the highest germination speeds, followed by Blue Ace (86.33%), Bilensoy (81.21%), and Sunter (80.29%). However, cultivar responses to coating did not follow a consistent pattern. Coating increased germination speed by approximately 6.03% in Bilensoy, 5.14% in Blue Ace, 0.66% in Icon, and 6.76% in Sunter, whereas it decreased germination speed by approximately 2.30% in Bolton. Similar genotypic variation persisted across storage and transportation. After transportation, Icon showed the highest cultivar mean (91.25%), whereas germination speed in Sunter decreased by approximately 4.50% compared with its pre-storage value. The three-way interaction further highlighted this variation, with germination speed across treatment combinations ranging from 75.25 to 95.50%. The highest value (95.50%) was recorded in coated Icon seeds after transportation, whereas the lowest value (75.25%) was observed in uncoated Sunter seeds at the same stage. This difference of about 20 percentage points shows that the effect of coating on germination speed was neither genotype-independent nor unidirectional; instead, it depended on the interaction among coating, genotype, and storage/transportation conditions (Table 2).

Table 2. Mean germination speed (%), germination percentage (%), and emergence speed (%) of alfalfa cultivars under different coating treatments and storage stages, with statistical groupings.

[1]Means followed by the same letter are not significantly different.

The higher germination speed observed in coated seeds generally aligns with previous studies showing that appropriate coating treatments can improve seed microenvironmental conditions and promote water uptake and early metabolic activation. Amirkhani et al. (2016, 2019) and Qiu et al. (2020) reported that appropriate biostimulant- and plant protein-based coatings could improve germination speed and uniformity, although the amount and formulation of the coating material determined the direction and magnitude of the response. Similarly, studies in alfalfa by Mehrabi et al. (2015), Bıçakcı et al. (2018), Süheri et al. (2019), and Öten and Tuzlacı (2024) showed that coating effects on germination performance may vary with environmental conditions and application characteristics. The significant cultivar × coating × storage interaction observed in the present study further supports this interpretation. In particular, coated Icon seeds reached the highest germination speed (95.50%) after transportation, whereas uncoated Sunter seeds fell to 75.25%, showing that the physiological advantage of coating was genotype-dependent. This genotypic variation is also consistent with findings from Jungers et al. (2016), Jabri et al. (2021), Xie et al. (2023), and Zhou et al. (2024), who reported that germination and responses to environmental stresses in alfalfa may vary by genetic background. Therefore, these findings show that high and stable germination speed in alfalfa depends not only on coating treatment but also on cultivar × coating × storage/transportation compatibility, highlighting the importance of cultivar-specific optimization of coating technologies in commercial seed production.

Germination Percentage

Analysis of variance revealed that germination percentage in alfalfa was significantly affected by coating and cultivar ($p < 0.01$), whereas the main effect of storage stage was not statistically significant. However, all coating × storage, cultivar × coating, cultivar × storage, and cultivar × coating × storage interactions were significant ($p < 0.01$), indicating that storage and transportation effects varied by coating status and genotype (Table 1). Based on the overall means, coating increased germination percentage from 86.40% in uncoated seeds to 89.42% in coated seeds, corresponding to an increase of approximately 3.50%. In contrast, the very similar mean values recorded before storage (88.05%), after storage (88.08%), and after transportation (87.60%) indicated that germination percentage was generally maintained throughout the process. However, the coating × storage interaction showed a different pattern. Germination percentage in uncoated seeds decreased from 87.25% before storage to 85.25% after transportation, whereas it increased in coated seeds from 88.85% to 89.95%. Consequently, the difference between coated and uncoated seeds increased from 1.60 percentage points before storage to 4.70 percentage points after transportation. These results indicate that although storage alone did not significantly affect germination, coating may help maintain germination percentage, particularly during the transportation stage after storage (Table 2).

Marked differences were observed among cultivars in their responses to coating and storage. Based on the overall means, Icon (91.38%) and Bolton (90.71%) recorded the highest germination percentages, followed by Blue Ace (89.38%), Bilensoy (84.58%), and Sunter (83.50%). The effect of coating also varied among genotypes. Compared with uncoated seeds, coating increased germination percentage by approximately 5.05% in Bilensoy, 4.47% in Blue Ace, 4.58% in Icon, and 4.91% in Sunter, but decreased it by 1.18% in Bolton. Regarding the cultivar × storage interaction, Icon and Bolton maintained high germination percentages throughout the experimental stages, whereas Sunter exhibited a more pronounced reduction, particularly after transportation. This genotypic variation became even more evident in the three-way interaction, with germination percentage ranging from 79.50 to 98.00% across treatment combinations. The highest value (98.00%) was recorded in coated Icon seeds after transportation, whereas the lowest value (79.50%) was observed in uncoated Sunter seeds at the same stage. In particular, the increase in coated Icon from 91.25% before storage to 98.00% after transportation, compared with the decrease in uncoated Sunter from 84.50% to 79.50%, demonstrates that the effect of coating under storage and transportation conditions was strongly associated with the

physiological characteristics of the cultivars. Therefore, the effect of coating on germination percentage cannot be adequately explained solely by an overall comparison between coated and uncoated seeds; the genotype × coating × storage/transportation interaction should also be considered (Table 2).

The overall increase in germination percentage associated with coating is consistent with previous studies reporting that appropriate coating materials can support seed physiological performance. Amirkhani et al. (2016, 2019) reported that appropriately formulated seed coatings could improve germination and early seedling performance, whereas Qiu et al. (2020) demonstrated that coating material and application rate are critical factors and that excessive coating may restrict water uptake and radicle emergence. Similarly, studies conducted specifically in alfalfa by Mehrabi et al. (2015), Bıçakcı et al. (2018), Süheri et al. (2019), and Öten and Tuzlacı (2024) reported that germination responses to coating treatments may vary depending on environmental conditions, coating material, and application characteristics. Sprey et al. (2025) also highlighted the importance of coating integrity, water relations, and storage stability in determining coated-seed performance, supporting the significant coating × storage interaction observed in the present study. In particular, the positive response to coating observed in Bilensoy, Blue Ace, Icon, and Sunter, compared with the slight reduction observed in Bolton, together with the 18.50-percentage-point difference between coated Icon (98.00%) and uncoated Sunter (79.50%) after transportation, clearly demonstrates that coating effectiveness is genotype-dependent. Overall, these findings indicate that high and stable germination percentage in alfalfa cannot be attributed solely to seed coating. Rather, evaluate the effectiveness of coating technologies alongside genotype and storage/transportation conditions. Particularly in genotypes that respond positively to coating, appropriate coating treatments may offer considerable potential to maintain physiological seed quality throughout commercial storage and distribution processes.

Emergence Speed

Analysis of variance revealed that emergence speed in alfalfa was significantly affected by the main effects of coating, storage stage, and cultivar, as well as by all coating × storage, cultivar × coating, cultivar × storage, and cultivar × coating × storage interactions ($p < 0.01$) (Table 1). Based on overall means, coating increased emergence speed from 83.08% in uncoated seeds to 85.95% in coated seeds, an increase of approximately 3.45%. Across storage stages, emergence speed was highest before storage (86.28%), decreased to 84.45% after storage, and fell further to 82.83% after transportation, indicating a progressive decline throughout storage and transportation. The coating × storage interaction also showed that the advantage conferred by coating varied by storage stage. Before storage, coated seeds showed an emergence speed of 89.05%, compared with 83.50% in uncoated seeds, a difference of 5.55 percentage points. This difference decreased to 1.80 percentage points after storage (85.35 vs. 83.55%) and to 1.25 percentage points after transportation (83.45 vs. 82.20%). Furthermore, from before storage to after transportation, emergence speed decreased by approximately 1.56% in uncoated seeds and by 6.29% in coated seeds. These findings indicate that although coating increased overall emergence speed, the initial advantage diminished as storage and transportation progressed. They also suggest that emergence speed may be more sensitive to storage and transportation conditions than germination-related traits and may therefore provide a useful indicator of seed vigor (Table 2).

Marked genotypic variation was observed among cultivars for emergence speed. Based on the overall means, Icon exhibited the highest emergence speed (90.58%), followed by Blue Ace (88.96%), Bolton (86.83%), Bilensoy (79.88%), and Sunter (76.33%). However, responses to coating differed considerably among cultivars. Compared with uncoated seeds, coating increased emergence speed from 72.67 to 80.00% in Sunter, corresponding to an increase of approximately 10.09%. Similarly, emergence speed increased from 84.08 to 89.58% in Bolton (approximately 6.54%) and from 78.67 to 81.08% in Bilensoy (approximately 3.06%). In contrast, Blue Ace decreased slightly, from 89.25 to 88.67% (approximately 0.65%), and Icon decreased slightly, from 90.75 to 90.42% (approximately 0.36%). The pronounced improvement observed in Sunter, which had the lowest emergence speed under uncoated conditions, indicates that coating provided a particularly beneficial effect in this relatively low-performing genotype. The cultivar × storage interaction also revealed substantial differences in the maintenance of emergence performance during storage and transportation. Icon maintained a high emergence speed throughout the experimental stages, with mean values of 89.00% before storage, 93.25% after storage, and 89.50% after transportation. Bolton also maintained relatively high performance, with values of 88.00%, 83.25%, and 89.25%. In contrast, emergence speed decreased from

84.63% before storage to 75.00% after transportation in Bilensoy, a reduction of approximately 11.38%, while Sunter decreased from 80.75% to 74.50%, a reduction of approximately 7.74%. The three-way interaction further emphasized these genotype-specific responses. Uncoated Icon showed the highest emergence speed (96.50%) after storage, whereas uncoated Sunter showed the lowest (68.50%) after both storage and transportation. In contrast, coated Sunter maintained emergence speeds of 79.00% after storage and 80.50% after transportation. Thus, coating improved emergence performance in Sunter by 10.50 percentage points after storage and 12.00 percentage points after transportation compared with the corresponding uncoated seeds. These findings indicate that coating may help mitigate losses in emergence performance in genotypes that are particularly sensitive to storage and transportation conditions. Overall, the response to coating was not uniform across cultivars but was strongly influenced by the cultivar × coating × storage/transportation interaction (Table 2).

The overall increase in emergence speed associated with coating is largely consistent with previous studies reporting that appropriate seed-coating systems can support early seedling performance. Amirkhani et al. (2016, 2019) reported that plant protein- and biostimulant-based coating systems could improve early seedling development, while Afzal et al. (2020) indicated that modern coating technologies may promote seedling establishment by delivering biostimulants and nutrients to the seed microenvironment. Similarly, Qiu et al. (2020) showed that coating effects depend on formulation and application rate, whereas Sprey et al. (2025) emphasized that coating performance may vary substantially with the physical properties of the coating material, moisture relations, and storage conditions. Findings reported for alfalfa by Bıçakcı et al. (2018) and Süheri et al. (2019) also support the view that coating treatments' effects on early-stage performance interact with environmental conditions. In the present study, although coating increased overall emergence speed, the progressive reduction in the initial advantage of coated seeds during storage and transportation indicates that the beneficial effect observed before storage did not necessarily translate into an equivalent advantage after prolonged storage and transportation. Furthermore, the pronounced improvement observed in Sunter following coating, compared with the slight reductions observed in Icon and Blue Ace, demonstrates a strong genotypic component in the response to coating. Collectively, these findings indicate that high and stable emergence performance in alfalfa cannot be attributed solely to coated seeds; rather, cultivar, coating treatment, and storage/transportation conditions should be evaluated jointly. Appropriate coating technologies may therefore be particularly important for maintaining early seedling establishment in genotypes whose emergence performance is more susceptible to deterioration during storage and transportation.

Emergence Percentage

Analysis of variance revealed that emergence percentage in alfalfa was significantly affected by the main effects of coating, storage stage, and cultivar, as well as by all two-way and three-way interactions among these factors ($p < 0.01$) (Table 1). Based on the overall means, coating increased emergence percentage from 83.77% in uncoated seeds to 86.32% in coated seeds, corresponding to a relative increase of approximately 3.04%. In contrast, emergence percentage declined progressively during storage and transportation, decreasing from 86.95% before storage to 85.25% after storage and further to 82.93% after transportation. Thus, emergence percentage decreased by approximately 4.62% from before storage to after transportation. This trend indicates that although coating generally supported seedling establishment, storage and particularly the subsequent transportation process may lead to a progressive decline in seed vigor. The significant coating × storage interaction further shows that the advantage conferred by coating depended on storage conditions and that emergence percentage may be a sensitive trait for assessing changes in physiological seed quality throughout the commercial seed supply chain (Table 3).

Genotypic differences played a major role in determining emergence percentage. Based on the overall means, Icon exhibited the highest emergence percentage (90.88%), followed by Blue Ace (89.29%), Bolton (87.83%), Bilensoy (80.33%), and Sunter (76.88%). However, responses to coating differed considerably among cultivars. Compared with uncoated seeds, coating increased emergence percentage by about 11.83% in Sunter, 3.27% in Bolton, and 3.16% in Bilensoy, whereas Blue Ace and Icon showed slight decreases of about 0.84% and 0.45%, respectively. In particular, Sunter, which exhibited the lowest emergence percentage under uncoated conditions (72.58%), increased to 81.17% following coating, demonstrating a pronounced beneficial effect of coating in this genotype with relatively low

initial performance. Responses to storage and transportation also varied among cultivars. From before storage to after transportation, emergence percentage decreased by approximately 12.12% in Bilensoy, 6.51% in Sunter, 3.92% in Blue Ace, and 1.80% in Bolton, whereas it increased slightly, by approximately 0.71%, in Icon. These differences became even more pronounced in the three-way interaction. Uncoated Icon reached the highest emergence percentage (97.00%) after storage, whereas uncoated Sunter exhibited the lowest value (68.00%) at the same stage. In contrast, emergence percentage in coated Sunter increased from 80.25% before storage to 81.25% after storage and 82.00% after transportation, suggesting that coating may help mitigate performance losses, particularly in genotypes sensitive to storage and transportation conditions. Therefore, the effect of coating on emergence percentage should be interpreted not simply as an overall difference between coated and uncoated seeds but rather as the outcome of a strong cultivar × coating × storage/transportation interaction (Table 3).

The overall increase in emergence percentage associated with coating generally aligns with previous studies showing that appropriate coating systems can support early seedling performance. Amirkhani et al. (2016, 2019) reported that plant protein- and biostimulant-based coatings could promote early plant development, while Afzal et al. (2020) emphasized that modern seed-coating technologies can improve seedling establishment by delivering active components, such as biostimulants and nutrients, directly to the seed microenvironment. Similarly, Qiu et al. (2020) demonstrated that coating performance depends on formulation and application rate, whereas Sprey et al. (2025) reported that the physical properties of coating materials and storage conditions may determine coating effectiveness. Findings from alfalfa by Mehrabi et al. (2015), Bıçakcı et al. (2018), and Öten and Tuzlacı (2024) also support the view that early-stage responses to coating treatments vary with application characteristics and environmental conditions. In the present study, the 11.83% increase in emergence percentage following coating in Sunter, along with the absence of the pronounced post-storage decline observed in uncoated Sunter seeds, suggests that coating benefits may be more pronounced in genotypes with lower initial performance or greater sensitivity to storage stress. In contrast, Icon's ability to maintain a high emergence percentage regardless of coating suggests that the genotype's intrinsic vigor may influence the magnitude of the response to coating. Collectively, these findings show that high and stable emergence percentage in alfalfa cannot be ensured solely through coated seeds. Instead, cultivar, coating treatment, and storage/transportation conditions should be jointly optimized, and appropriate coating technologies may play a particularly important role in maintaining seedling establishment in genotypes susceptible to performance losses during storage.

Number of Normal Seedlings

Analysis of variance revealed that the number of normal seedlings in alfalfa was significantly affected by the main effects of coating, storage stage, and cultivar, as well as by all two-way and three-way interactions among these factors ($p < 0.01$) (Table 1). Based on the overall means, coating increased the number of normal seedlings from 91.03 in uncoated seeds to 91.83 in coated seeds, corresponding to a modest increase of approximately 0.88%. In contrast, the number of normal seedlings decreased from 93.28 before storage to 90.68 after storage and 90.35 after transportation, representing reductions of approximately 2.79% and 3.14%, respectively, relative to the pre-storage value. The coating × storage interaction indicated that the effect of coating became particularly relevant after storage. At this stage, coated seeds maintained 91.75 normal seedlings, compared with 89.60 in uncoated seeds. In contrast, before storage, uncoated and coated seeds produced 93.20 and 93.35 normal seedlings, respectively, and belonged to the same statistical group, while after transportation the corresponding values converged to 90.30 and 90.40. These results indicate that the protective effect of coating was not consistent across all stages. Therefore, despite the relatively small overall effect of coating, its ability to reduce losses in the number of normal seedlings after storage may be a more biologically and technologically meaningful benefit for maintaining commercial seed quality (Table 3).

Marked differences among cultivars were observed in their capacity to produce normal seedlings. Based on the overall means, Blue Ace exhibited the highest number of normal seedlings (93.46), followed by Icon (92.25) and Bolton (91.96), whereas Bilensoy (90.29) and particularly Sunter (89.21) exhibited lower values. However, both the direction and magnitude of the response to coating differed substantially among cultivars. Coating increased the number of normal seedlings in Sunter from 86.58 to 91.83, corresponding to a pronounced increase of approximately 6.06%. More modest increases of

approximately 1.02% and 0.82% were observed in Bilensoy and Bolton, respectively, whereas decreases of approximately 0.62% and 2.50% were observed in Blue Ace and Icon, respectively. The cultivar × storage interaction also demonstrated that genotypes differed in their ability to maintain normal seedling production during storage and transportation. Blue Ace maintained a high number of normal seedlings before and after storage, whereas Icon exhibited a relatively high value of 93.13 after transportation. In contrast, Bilensoy declined from 94.88 before storage to 86.63 after transportation. The three-way interaction further highlighted this genotypic variation, with values ranging from 80.00 to 97.00 normal seedlings across treatment combinations. The highest value (97.00) was recorded for coated Blue Ace before storage, whereas the lowest value (80.00) was observed for uncoated Sunter after storage. Notably, while the number of normal seedlings in uncoated Sunter decreased to 80.00 after storage, coated Sunter remained at 92.00, a difference of 12 seedlings. This finding demonstrates that coating substantially limited storage-related losses in this genotype. Consequently, evaluation of the overall coating mean alone may mask strong genotype-specific responses, emphasizing the importance of assessing coating effectiveness within the context of cultivar × storage interactions (Table 3).

Table 3. Mean emergence percentage (%), number of normal seedlings, and number of abnormal seedlings of alfalfa cultivars under different coating treatments and storage stages, with statistical groupings.

Coating	Storage	Cultivars					Mean
		Bilensoy	Blue Ace	Bolton	Icon	Sunter	
Emergence Percentage (%)

[1]Means followed by the same letter are not significantly different.

The results show that the effect of seed coating on normal seedling production depended on storage conditions and genotypic characteristics rather than providing a direct, uniform improvement across all genotypes. Amirkhani et al. (2019) reported that appropriate coating components could support early plant development, whereas Qiu et al. (2020) showed that the effectiveness of biostimulant-containing coatings on germination and seedling establishment may vary by coating formulation and plant material. Afzal et al. (2020) also emphasized that modern coating technologies can support seedling establishment by delivering active compounds to the seed microenvironment. Furthermore, the variable responses to application and environmental conditions reported in alfalfa by Bıçakcı et al. (2018) and Öten and Tuzlacı (2024) are consistent with the strong cultivar × coating × storage interaction observed in the present study. In this context, Blue Ace showed the highest overall capacity for normal seedling production but gained no additional benefit from coating, whereas coating improved the number of normal seedlings by approximately 6.06% in Sunter, which had lower initial performance. More importantly, the 12-seed difference between uncoated and coated Sunter after storage shows that, beyond the modest overall coating effect of only 0.88%, coating may provide substantial protection in genotypes sensitive to storage-related deterioration. Overall, these findings indicate that high and stable production of normal seedlings in alfalfa cannot be ensured solely through coated seeds. Rather, evaluate the effectiveness of coating technologies alongside genotype and storage/transportation conditions, and develop genotype-specific coating strategies, particularly for cultivars susceptible to storage-induced vigor losses.

Number of Abnormal Seedlings

Analysis of variance revealed that the number of abnormal seedlings in alfalfa was significantly affected by the main effects of storage stage and cultivar ($p < 0.01$), whereas the main effect of coating was not statistically significant. However, all coating × storage, cultivar × coating, cultivar × storage, and cultivar × coating × storage interactions were significant ($p < 0.01$), demonstrating that the effect of coating on abnormal seedling formation was neither direct nor uniform but varied depending on genotype and storage stage (Table 1). Based on the overall means, coating reduced the number of abnormal seedlings only slightly, from 3.53 in uncoated seeds to 3.47 in coated seeds, corresponding to a reduction of approximately 1.70%. In contrast, the number of abnormal seedlings increased from 2.20 before storage to 3.28 after storage and 5.03 after transportation, representing increases of 49.09% and 128.64%, respectively, relative to the pre-storage value. The coating × storage interaction also showed that this trend differed by coating status. From before storage to after transportation, the number of abnormal seedlings increased from 1.90 to 5.25 in uncoated seeds (176.32%), whereas it increased from 2.50 to 4.80 in coated seeds (92.00%). Thus, although coating did not reduce abnormal seedling formation before storage, it partially limited the increase after storage and transportation. This finding suggests that the potential protective effect of coating may become more evident after seeds are exposed to storage and transportation processes (Table 3).

Marked genotypic variation was observed in abnormal seedling formation. Based on the overall means, Bilensoy exhibited the highest number of abnormal seedlings (5.08), followed by Sunter (3.79) and Icon (3.29), whereas Blue Ace (2.75) and Bolton (2.58) exhibited the lowest values. However, the response direction to coating differed substantially among cultivars. Coating increased the number of abnormal seedlings by approximately 6.71% in Bilensoy, 36.05% in Blue Ace, and 19.33% in Icon, whereas Bolton and Sunter showed reductions of approximately 22.95% and 31.56%, respectively. The response observed in Sunter was particularly noteworthy, indicating that coating may substantially reduce abnormal seedling formation in this cultivar. The cultivar × storage interaction also revealed differences in physiological stability among genotypes throughout storage and transportation. After transportation,

Bilensoy exhibited the highest number of abnormal seedlings (8.88), whereas Bolton had the lowest value (3.38). The three-way interaction further emphasized the magnitude of these genotype-specific responses, with the number of abnormal seedlings ranging from 1.25 to 9.75 across treatment combinations. The highest value (9.75) was recorded for coated Bilensoy after transportation, whereas the lowest value (1.25) was observed for coated Blue Ace before storage. More importantly, after transportation, the number of abnormal seedlings in Sunter decreased from 6.75 in uncoated seeds to 1.75 in coated seeds, showing that coating strongly mitigated the adverse effects of transportation in this cultivar. In contrast, at the same stage, coated Bilensoy produced 9.75 abnormal seedlings compared with 8.00 in uncoated seeds. This contrasting response shows that coating did not protect all genotypes and that the overall coating mean may mask opposing cultivar-specific responses (Table 3).

The marked increase in abnormal seedlings after storage, and particularly transportation, suggests that changes in seed physiological quality during these processes may impair normal seedling development. Considering that seed aging is associated with deterioration of membrane integrity, alterations in metabolic and enzymatic activities, and reductions in cellular repair capacity, the present findings are generally consistent with those of Čupić et al. (2005) and Behtari et al. (2014), who reported that storage and aging can affect seed quality in alfalfa. Although the main effect of coating was not significant, the lower number of abnormal seedlings observed in coated seeds after storage and transportation indicates that coating effectiveness should be evaluated in interaction with storage conditions. Pedrini et al. (2017) emphasized that the effects of coating technologies on seedling establishment may vary depending on coating material and environmental conditions, while findings reported in alfalfa by Bıçakcı et al. (2018), Arslan et al. (2020), and Öten and Tuzlacı (2024) similarly demonstrated that early seedling responses to coating treatments may differ according to application and stress conditions. In the present study, the reduction in abnormal seedling formation following coating in Sunter and Bolton, compared with the increases observed in Bilensoy, Blue Ace, and Icon, is particularly important and demonstrates that coating technology should not be considered a genotype-independent, universally beneficial treatment. Overall, the findings indicate that abnormal seedling formation was determined primarily by storage/transportation conditions and genotypic characteristics rather than by the independent effect of coating. Coating, in turn, could exert either protective or adverse effects through its interactions with these factors. Therefore, optimization of coating technologies in alfalfa should consider not only mean seedling performance but also genotype-specific variation in abnormal seedling formation following storage and transportation as an important criterion of seed vigor and physiological quality.

Number of Hard Seeds

Analysis of variance revealed that the number of hard seeds in alfalfa was significantly affected by the main effects of coating, storage stage, and cultivar ($p < 0.01$). The cultivar × coating and cultivar × coating × storage interactions were also significant ($p < 0.01$), whereas the coating × storage and cultivar × storage interactions were not significant, indicating that the effect of coating varied primarily according to genotype (Table 1). Based on the overall means, the number of hard seeds decreased from 0.93 in uncoated seeds to 0.58 in coated seeds, corresponding to a reduction of approximately 37.63%. Across storage stages, the number of hard seeds decreased from 0.98 before storage to 0.58 after storage, representing a reduction of approximately 40.82%. Although the value subsequently increased to 0.73 after transportation, it remained approximately 25.51% below the pre-storage level. These findings indicate that both coating and storage may reduce hardseededness. However, because the coating × storage interaction was not significant, the results do not support the conclusion that these two factors systematically modified each other's effects. Therefore, the most notable finding regarding hardseededness was not simply the overall reduction associated with coating, but rather the genotype-dependent variation in this response (Table 4).

Cultivars showed marked variation in the number of hard seeds. Bolton exhibited the highest overall value (1.67), followed by Icon (0.92), Blue Ace and Sunter (0.54 each), whereas Bilensoy exhibited the lowest number of hard seeds (0.13). The significant cultivar × coating interaction further demonstrated that both the direction and magnitude of the coating response varied among genotypes. Coating markedly reduced hard seeds in Bolton (2.25 to 1.08) and Icon (1.33 to 0.50), while Bilensoy showed a smaller reduction (0.17 to 0.08). In contrast, coating increased hard seeds from 0.42 to 0.67 in Blue Ace and from 0.50 to 0.58 in Sunter. The significant three-way interaction further confirmed differential genotype responses to coating and storage, with values ranging from 0.00 to 2.25 hard seeds across treatment combinations. Notably, the number of hard seeds in uncoated Bolton remained constant at

2.25 before storage, after storage, and after transportation, whereas in coated Bolton it decreased from 2.25 before storage to 0.25 after storage and 0.75 after transportation. In contrast, no hard seeds were recorded for uncoated Bilensoy after transportation, coated Bilensoy before and after storage, or coated Icon after transportation. These findings suggest that in genotypes with a relatively high tendency toward hardseededness, such as Bolton, coating may have greater potential to reduce the number of hard seeds following storage. However, because the same response was not observed in genotypes such as Blue Ace and Sunter, evaluate the effects of coating on a genotype-specific basis (Table 4).

Hardseededness is a major manifestation of physical dormancy in legumes, characterized by seed-coat impermeability to water and gases, and can directly influence the initiation of germination and the temporal uniformity of seedling establishment in alfalfa. Galussi et al. (2015) reported that hardseededness in alfalfa is closely associated with seed-coat structural characteristics, and the marked difference observed between Bolton and Bilensoy in the present study further supports a strong genotypic component underlying this trait. The decrease in the number of hard seeds from 0.98 before storage to 0.58 after storage also aligns with Čupić et al. (2005), who reported that the proportion of hard seeds in alfalfa may decline as storage duration increases. Although coating reduced the overall number of hard seeds by approximately 37.63%, suggesting that the coating process may alter seed-surface processes and water uptake, the present experimental data do not directly establish the physiological mechanism underlying this reduction. Therefore, attributing the observed effect solely to changes in seed-coat permeability would not be justified. More importantly, the pronounced reductions observed in Bolton and Icon, compared with the slight increases observed in Blue Ace and Sunter, demonstrate that the effect of coating on physical dormancy was genotype-dependent. Overall, these findings indicate that genotype strongly influences hardseededness, while coating and storage can further modify this trait. Consequently, seed technologies aimed at achieving rapid and uniform seedling establishment in alfalfa should consider not only the overall effect of coating but also cultivar-specific levels of hardseededness and their changes during storage following coating.

Table 4. Mean number of hard seeds and dead seeds of alfalfa cultivars under different coating treatments and storage stages, with statistical groupings.

[1]Means followed by the same letter are not significantly different.

Number of Dead Seeds

Analysis of variance revealed that the number of dead seeds in alfalfa was significantly affected by the main effects of storage stage and cultivar ($p < 0.01$), whereas the main effect of coating was not statistically significant. However, all coating × storage, cultivar × coating, cultivar × storage, and cultivar × coating × storage interactions were significant ($p < 0.01$), showing that the effect of coating on seed viability depended on genotype and storage stage rather than being direct and broadly generalizable (Table 1). Based on the overall means, the number of dead seeds was 4.50 in uncoated seeds and 4.12 in coated seeds, corresponding to a numerical reduction of approximately 8.44% following coating. However, because the main effect of coating was not statistically significant, this numerical difference should not be interpreted as a general advantage of coating. In contrast, storage stage had a pronounced effect. The number of dead seeds increased from 3.55 before storage to 5.48 after storage, representing an increase of approximately 54.37%, and subsequently decreased to 3.90 after transportation, approaching the pre-storage level. The significant coating × storage interaction also showed that this response differed by coating status. After storage, the number of dead seeds was 6.15 in uncoated seeds compared with 4.80 in coated seeds, suggesting that coating may have limited seed mortality at this stage. In contrast, after transportation, coated seeds exhibited a higher value than uncoated seeds (4.30 vs. 3.50). These findings demonstrate that the effect of coating on the maintenance of seed viability was not consistent throughout the experimental stages and that its effects should therefore be evaluated according to storage stage rather than solely on the basis of overall means (Table 4).

Marked genotypic variation was observed in the number of dead seeds. Based on the overall means, Sunter exhibited the highest value (6.50), followed by Bilensoy (4.50), Bolton (3.79), Icon (3.54), and Blue Ace (3.21). However, the significant cultivar × coating interaction demonstrated that responses to coating were more complex than the overall cultivar means alone would suggest. Coating reduced the number of dead seeds by approximately 22.83% in Bilensoy, 12.28% in Blue Ace, and 47.06% in Sunter, whereas it increased the number of dead seeds by approximately 33.23% and 114.67% in Bolton and Icon, respectively. The high F-value for the three-way interaction ($F = 47.082$) further indicates that these genotype-specific responses became more pronounced across storage stages. The treatment combinations exhibited a wide range of variation, from 0.25 to 15.00 dead seeds. The highest number of dead seeds (15.00) was recorded for uncoated Sunter after storage, whereas the lowest value (0.25) was observed for uncoated Icon after transportation. Notably, Sunter after storage showed 15.00 dead seeds in uncoated seeds but only 3.00 in coated seeds, indicating that coating markedly limited storage-associated seed mortality in this cultivar. In contrast, coating increased the overall number of dead seeds in Icon from 2.25 to 4.83, demonstrating that the same treatment may produce contrasting responses among cultivars. Therefore, the effectiveness of coating technologies should not be reduced to a simple coated-versus-uncoated comparison but should instead be evaluated within the context of cultivar × coating × storage interactions (Table 4).

The marked increase in dead seeds after storage suggests that seeds underwent physiological deterioration during storage and that viability losses were sensitive to storage conditions. Seed aging has been associated with deterioration of membrane integrity, reductions in metabolic and enzymatic activity, and the accumulation of oxidative damage, processes that may ultimately reduce seed viability and germination ability (McDonald, 1999; Walters et al., 2010). Similarly, seed longevity depends not only on environmental conditions but also on genetic background, initial seed quality, and seed moisture content (Walters et al., 2004; Rajjou and Debeaujon, 2008; Rajjou et al., 2012). In this context, the higher number of dead seeds observed in Sunter, together with the pronounced loss of viability in its uncoated seeds after storage, supports substantial cultivar-specific differences in storage tolerance. Although coating markedly limited this loss in Sunter, the increases in dead seeds observed in Bolton and Icon indicate that coating did not provide a uniform protective effect across cultivars. This genotype-dependent response is consistent with Pedrini et al. (2017), who argue that the physical and chemical properties of coating materials may alter water and gas exchange in the seed microenvironment, potentially resulting in beneficial, neutral, or adverse effects depending on the seed and coating system.

Overall, the findings indicate that genotype is an important determinant of seed viability maintenance during storage in alfalfa and that coating should not be regarded as a universally protective strategy. Instead, coating formulations should be optimized according to genotype-specific storage tolerance, and identifying cultivar × coating combinations that effectively limit dead seed formation after storage may provide a more rational approach to maintaining commercial seed quality.

CONCLUSION

This study showed that the effects of seed coating, storage, and transportation on the physiological quality of alfalfa seeds largely depended on cultivar and the specific seed quality trait evaluated. Overall, seed coating improved germination speed and germination percentage, and the smaller performance losses in coated seeds compared with uncoated seeds after transportation suggest that appropriate coating treatments may help maintain germination performance throughout the commercial storage and distribution chain. In contrast, the progressive reductions in emergence speed and emergence percentage during storage and transportation indicate that seed vigor may be more sensitive to environmental and physical stresses associated with these processes, even when germination percentage remains relatively stable. The reduction in normal seedlings, along with increases in abnormal seedlings and dead seeds, further shows that storage and transportation effects on physiological seed quality cannot be assessed based on germination percentage alone. Marked differences were observed among cultivars: Icon and Bolton generally performed well for germination and emergence traits, Blue Ace was distinguished by its high capacity to produce normal seedlings, whereas Sunter showed lower and more variable performance for several traits. Nevertheless, the improved emergence and normal seedling production and the marked reduction in dead seed formation after storage observed in coated Sunter seeds, together with the limited or adverse responses to coating observed in some other cultivars, clearly demonstrate that coating does not provide a universal, genotype-independent advantage. In particular, the significance of cultivar × coating × storage/transportation interactions for most of the evaluated traits indicates that the effectiveness of coating technologies in commercial alfalfa seed production should be assessed not only on the basis of initial germination performance but also according to their capacity to maintain seed vigor and viability after storage and transportation. Overall, maintaining high and stable seed quality requires genotype-specific optimization of coating formulations and storage and transportation protocols. An integrated assessment of germination, emergence, normal seedling development, and viability losses is therefore recommended as a fundamental approach for improving the effectiveness and reliability of coated alfalfa seeds under commercial conditions.

ABSTRACT
Rapid, high germination is a fundamental component of seed quality in sugar beet, as it contributes to uniform crop establishment and optimal plant density. This study aimed to determine the effects of seed coating, storage, and transportation processes on the germination performance of different sugar beet cultivars. Uncoated and coated seeds of five cultivars, namely Balboa, Gregoria, Juncal, Preziosa, and Terranova, were used. Seeds were evaluated before storage, after approximately six months of storage at 5 °C and 60% relative humidity, and following a subsequent 16-h transportation period. Germination rate and germination percentage were used as the principal indicators of physiological seed performance. Analysis of variance revealed that coating, storage, cultivar, and their interactions significantly affected germination performance. Overall, germination rate decreased from 85.67% in uncoated seeds to 69.92% in coated seeds, corresponding to a reduction of approximately 18.38% due to coating. Among the cultivars, Terranova had the highest germination rate (83.54%), while Balboa had the lowest (69.21%). Similarly, germination percentage declined from 95.62% in uncoated seeds to 78.93% in coated seeds, representing a reduction of approximately 17.45%. Mean germination percentage was 92.50% before storage, decreased to 83.70% after storage, and partially recovered to 85.63% after transportation. Terranova (93.88%) and Gregoria (89.71%) maintained comparatively high germination performance, whereas Balboa had the lowest mean value (80.58%). The pronounced cultivar-specific responses to coating demonstrated that germination performance was strongly influenced by genotype × seed processing × storage interactions. In conclusion, seed coating and storage protocols should be optimized on a cultivar-specific basis to preserve high germination performance in commercial sugar beet seed production.
Keywords: Germination Percentage, Germination Rate, Seed Coating, Storage, Transportation.

INTRODUCTION
Sugar beet (*Beta vulgaris* L.) is one of the principal raw materials of the sugar industry, and the establishment of a rapid and uniform plant stand is of critical importance for achieving economically viable and sustainable production. Because plant losses after sowing in sugar beet cannot be adequately compensated for, using seeds with high physiological quality is a fundamental factor directly affecting successful crop establishment and subsequent production performance (Kockelmann and Meyer, 2006; Kockelmann et al., 2010). Therefore, seed quality assessment should consider not only final germination percentage but also traits reflecting germination speed and uniformity. In particular, germination speed and germination capacity are regarded as important indicators of seed vigor and the ability of seeds to germinate under varying environmental conditions (Finch-Savage and Bassel, 2016; Podlaski and Chomontowski, 2020). Indeed, sugar beet seed lots with similar final germination percentages may differ substantially in terms of germination speed and uniformity (Podlaski and Chomontowski, 2020). The germination performance of sugar beet seeds depends on the combined effects of numerous factors, including genotype, conditions during seed development and maturation, harvest timing, initial physiological quality, seed-processing practices, and storage conditions (Finch-Savage and Bassel, 2016; Leprince et al., 2016). In particular, environmental conditions experienced during seed development and maturation may influence seed dormancy, vigor, germination speed, and storage potential (Mirzaei and Hemayati, 2022). In sugar beet, harvest maturity and seed moisture content have been reported to play decisive roles in germination capacity and storability, whereas unfavorable storage

conditions may accelerate seed deterioration and consequently reduce germination performance (Śliwińska et al., 1999; Śliwińska, 2003). During storage, temperature, relative humidity, and seed moisture content are among the major determinants of the rate of seed aging, while appropriate storage conditions contribute to the prolonged maintenance of seed viability and vigor (Walters et al., 2005; Gürel, 2020; Solberg et al., 2020; Zinsmeister et al., 2020).

In modern sugar beet production, seeds are commonly coated or pelleted to provide standardized physical characteristics suitable for precision sowing and to enable controlled application of various active ingredients onto the seed surface (Rocha et al., 2019; Afzal et al., 2020). However, the physical and physicochemical properties of coating materials may affect seed water uptake and gas exchange, thereby modifying the initiation and progression of germination. In particular, excessive mechanical resistance of the coating layer, insufficient porosity, or inappropriate water permeability may delay imbibition and radicle emergence, ultimately reducing germination speed (Afzal et al., 2020; Ma et al., 2022). In addition to the physical properties of the pericarp, the presence of germination-inhibiting compounds such as phenolic substances, abscisic acid, and various ions in sugar beet seeds further increases the importance of interactions between the seed and coating material (Duan and Burris, 1997; Ignatz et al., 2019). Furthermore, the mechanical strength, porosity, water resistance, and chemical properties of pellets have been reported to substantially influence germination performance, particularly under suboptimal moisture conditions (Podlaski et al., 2019).

Maintaining germination performance in coated seeds until sowing depends not only on the quality of the coating process but also on the conditions encountered during storage and transportation. Physiological deterioration during storage may reduce germination speed and seed vigor before any detectable loss in final viability occurs; therefore, germination speed is a sensitive indicator of early storage-related deterioration in seed quality (Solberg et al., 2020; Zinsmeister et al., 2020). In coated seeds, maintaining coating integrity is also critical in addition to providing appropriate storage conditions. Binder and filler characteristics, along with drying conditions, can affect coating stability, water permeability, and disintegration behavior (Afzal et al., 2020; Paravar et al., 2023; Köhl et al., 2024). Moreover, vibration, friction, and mechanical stresses encountered during transportation may alter coating structure and subsequently influence seed water uptake and germination behavior. Consequently, coating, storage, and transportation should not be considered independent processes but rather sequential factors that collectively determine seed germination performance from seed processing to sowing.

Previous studies on sugar beet have demonstrated the effects of coating and pelleting characteristics, priming, polishing and washing treatments, and storage conditions on seed germination performance (Duan and Burris, 1997; Capron et al., 2000; Marcinek et al., 2011; Ignatz et al., 2019; Podlaski et al., 2019; Chomontowski et al., 2020; Gürel, 2020). Nevertheless, studies simultaneously evaluating the sequential effects of coating, storage, and transportation on the germination characteristics of different sugar beet cultivars remain limited. Furthermore, genetic and physiological differences among cultivars suggest that their responses to coating, storage, and transportation processes may be genotype-dependent. Accordingly, the present study aimed to compare germination speed and germination capacity of uncoated and coated seeds from different sugar beet cultivars before storage, after storage, and after storage plus transportation, and to determine cultivar × coating × storage/transportation interactions. The study therefore sought to elucidate both the individual and combined effects of coating and storage/transportation processes on the germination performance of commercial sugar beet seeds and to provide a scientific basis for practices aimed at preserving seed quality until sowing.

MATERIALS AND METHODS

Material

The study was conducted between 2024 and 2025 in the laboratories of the Ankara Seed Registration and Certification Directorate to determine the viability and early seedling growth performance of uncoated and coated sugar beet (*Beta vulgaris* L.) seeds before storage, after storage, and after storage plus transportation. Seeds of five sugar beet cultivars, namely Balboa, Gregoria, Juncal, Preziosa, and Terranova, were used as plant material. To enable a direct comparison of the coating treatment, seeds from the same seed lot of each cultivar were divided into two groups: coated and uncoated. Seed coating was performed by ABEL Ziraat A.Ş. at a 1:1 (w/w) ratio, corresponding to the application of 1 kg of coating material per 1 kg of seed. The cultivars used in the study differed in their agronomic

characteristics and disease tolerance. Balboa is characterized by its monogerm and root-sugar type and tolerance to *Rhizomania*; Gregoria by high resistance to *Rhizomania* and tolerance to *Cercospora* and powdery mildew; Juncal by its monogerm and root-sugar type, *Fusarium* tolerance, and suitability for early sowing; Preziosa by high resistance to *Rhizomania* and tolerance to cyst nematodes and *Cercospora*; and Terranova by high resistance to *Rhizomania* and tolerance to *Cercospora* and powdery mildew. In addition, Balboa and Juncal achieved mean root yields of 8.8 and 7.88 t ha^{-1}, respectively, in registration trials, with sugar contents of 17.10% for Balboa and 15.35% for Juncal. Thus, cultivars with different genetic and agronomic characteristics enabled cultivar-specific comparisons of responses to coating, storage, and transportation.

Methods

Germination performance before storage

To determine pre-storage germination performance, seeds were taken from harvested plants that had not yet undergone storage or transportation. Standard germination tests were conducted in accordance with the rules of the International Seed Testing Association (ISTA) to determine the initial physiological quality of the seeds. Germination speed, germination capacity, emergence speed, emergence capacity, number of normal seedlings, and number of dead seeds were determined. We used these values as baseline data to evaluate changes after storage and transportation (ISTA, 2025).

Germination performance after storage

To determine the effects of storage on seed viability and early seedling development, the seeds were stored for approximately six months at +5 °C and 60% relative humidity. At the end of the storage period, the physiological quality characteristics of the seeds were reassessed in accordance with ISTA rules. Standard germination tests were conducted, and germination speed, germination capacity, emergence speed, emergence capacity, number of normal seedlings, and number of dead seeds were determined. The results were compared with the pre-storage values to assess the effects of the six-month storage period on seed viability and early seedling development (ISTA, 2025).

Germination performance before storage after storage + transportation

To determine the effects of transportation following storage on seed performance, seeds stored for approximately six months at +5 °C and 60% relative humidity were subsequently subjected to a 16-h transportation period. Following transportation, seed viability performance was evaluated in accordance with ISTA rules. Standard germination tests were conducted to determine germination speed, germination capacity, emergence speed, emergence capacity, number of normal seedlings, and number of dead seeds. The resulting data were compared with those obtained before and after storage to determine the sequential effects of storage and subsequent transportation on seed viability and early seedling development (ISTA, 2025).

Statistical Analysis

The experiment data were analyzed using analysis of variance (ANOVA) in JMP statistical software. For factors and interactions found to be statistically significant by ANOVA, mean comparisons were performed using Tukey's Honestly Significant Difference (HSD) multiple comparison test available in JMP (JMP, 2023). Statistical differences were evaluated at the 5% significance level ($p < 0.05$), and differences among means were indicated by letter groupings.

RESULTS AND DISCUSSION

Germination Speed

The significant effects ($p < 0.01$) of coating, storage, and cultivar, as well as their two-way and three-way interactions, on germination speed demonstrated that early germination performance in sugar beet was jointly influenced by genotype, seed-processing technology, and storage conditions (Table 1). Across all treatments, mean germination speed decreased from 85.67% in uncoated seeds to 69.92% in coated seeds, corresponding to a pronounced reduction of 18.38% due to coating (Table 2). This reduction may reflect changes in water and gas exchange caused by the coating layer, slower imbibition dynamics, and restricted leaching of germination-inhibiting compounds from the pericarp. Duan and Burris (1997) reported that polymer film coating induced genotype-dependent responses in sugar beet and could significantly reduce germination in sensitive seed lots, while Kulan and Kaya (2016) found

that uncoated seeds could exhibit higher germination and emergence performance under laboratory conditions. Similarly, Podlaski et al. (2019) demonstrated that pellet porosity, mechanical strength, water resistance, and chemical properties could influence germination behavior. Therefore, the technological advantages provided by seed coating, particularly with respect to early germination, should be evaluated by considering both the physical properties of the coating material and its compatibility with the genotype.

The marked differences among cultivars in their responses to coating further support this interpretation. The reduction in germination speed after coating reached 36.36% in Balboa, whereas it was limited to only 5.53% in Terranova and 9.92% in Gregoria, indicating that the cultivar × coating interaction was also biologically meaningful (Table 2). Mirzaei and Hemayati (2022) reported that germination characteristics in sugar beet could be significantly influenced by genotype and genotype × environment interactions, while Podlaski and Chomontowski (2020) demonstrated that seeds with similar final germination levels could nevertheless differ in vigor and early germination performance. In the present study, Terranova and Gregoria maintained relatively higher germination speed after coating, whereas Balboa exhibited a markedly more sensitive response, demonstrating that coating technologies do not induce identical physiological responses across all cultivars. These findings indicate that, in commercial seed-coating practices, not only the coating formulation but also cultivar × coating compatibility should be considered as an important criterion for optimization.

*: $p<0.05$; **: $p<0.01$

Storage markedly affected germination speed, with the overall mean decreasing from 82.13% before storage to 73.53% after storage, corresponding to a reduction of 10.47%. This reduction was 8.80% in uncoated seeds and reached 12.46% in coated seeds, suggesting that coated seeds may be more sensitive to physiological changes occurring during storage (Table 2). The effects of seed aging and storage conditions on germination performance in sugar beet have previously been reported by Śliwińska (2003) and Gürel (2020), whereas appropriate seed-processing and priming treatments have been shown to mitigate performance losses during storage and under low-temperature conditions (Capron et al., 2000; Tohidloo et al., 2015; Chomontowski et al., 2020). In the three-way interaction, germination speed

ranged widely from 53.25 to 97.00%. The lowest value was observed in coated Balboa seeds after storage, whereas the highest values were recorded for uncoated Terranova seeds before storage and uncoated Preziosa seeds after transportation. This wide variation indicates that germination speed was determined primarily by the cultivar × coating × storage/transportation combination rather than by any single factor. These results suggest that cultivar-specific optimization of coating technology and storage conditions may provide a more effective approach for maintaining early germination performance in sugar beet seeds.

Table 2. Mean germination speed (%), germination percentage (%), and emergence speed (%) of sugar beet cultivars under different coating and storage stages, with statistical groupings.

Germination Percentage

The significant effects of coating, storage, and cultivar, as well as their two-way and three-way interactions, on germination percentage demonstrated that seed performance was determined by the combined effects of genotype, seed processing, and storage conditions rather than by a single factor (Table 1). The decrease in germination percentage from 95.62% in uncoated seeds to 78.93% in coated seeds, a reduction of approximately 17.45%, may be associated with the coating material's physical effects on imbibition and gas exchange (Table 2). In addition to restricting water and oxygen uptake, the coating layer may delay the leaching of water-soluble inhibitors present in the pericarp, thereby limiting germination, particularly in sensitive seeds. Duan and Burris (1997) reported that polymer film coating could reduce germination in sugar beet depending on genotype and seed lot, while Kulan and Kaya (2016) found that uncoated seeds exhibited higher germination performance under laboratory conditions. Podlaski et al. (2019) further demonstrated that pellet porosity, mechanical strength, water resistance, and chemical composition were important determinants of germination behavior. Conversely, reports that treatments such as polishing and washing can improve germination by reducing ABA and other inhibitory compounds in the pericarp (Ignatz et al., 2019) suggest that the effect of coating depends not merely on the presence of the coating itself but also on the physical and physiological interactions among the seed, pericarp, and coating material.

The response to coating varied considerably among cultivars, highlighting the critical role of genotypic differences in coating performance. The reduction in germination percentage due to coating reached 27.94% in Balboa and 23.19% in Preziosa, whereas the corresponding losses were limited to 10.31% in Gregoria and 11.63% in Terranova. Across all treatments, Terranova had the highest germination percentage at 93.88%, whereas Balboa had the lowest at 80.58%. Among coated seeds, Terranova maintained a relatively high germination percentage of 88.08%, while that of Balboa decreased to 67.50% (Table 2). These differences demonstrate that the same coating technology does not produce equivalent physiological responses across genotypes. The findings of Mirzaei and Hemayati (2022), who reported significant effects of genotype and genotype × environment interactions on germination characteristics in sugar beet, support this interpretation. Similarly, differences in early germination behavior between high- and low-vigor seeds despite similar final germination levels emphasize the importance of initial seed quality and genotypic characteristics in determining post-coating performance (Chomontowski et al., 2020). Therefore, the substantial losses observed particularly in Balboa and Preziosa indicate the importance of considering genotype-specific coating formulations and cultivar × coating compatibility rather than adopting a uniform coating approach in commercial seed-processing systems.

Storage further accentuated the effect of coating on germination percentage. Overall germination decreased from 92.50% before storage to 83.70% after storage; more importantly, this reduction was only 2.38% in uncoated seeds but reached 17.31% in coated seeds (Table 2). Although germination partially recovered after transportation, it did not return to the pre-storage level. Because controlled aging can reduce germination performance in sugar beet (Śliwińska, 2003) and storage performance depends on factors such as initial seed quality, temperature, and relative humidity (Gürel, 2020), these results indicate that the effects of coating and storage cannot be considered independently. In contrast, appropriate seed-processing and priming treatments have been reported to mitigate performance losses during storage and under low-temperature conditions (Capron et al., 2000; Tohidloo et al., 2015; Chomontowski et al., 2020). Therefore, maintaining germination percentage in sugar beet depends not only on high initial seed quality but also on cultivar × coating × storage/transportation compatibility. Accordingly, cultivar-specific optimization of coating physical properties and storage stability appears critical for maintaining commercial seed quality until sowing.

Emergence Speed

The significant effects of coating, storage, and cultivar on emergence speed, together with significant cultivar × coating, cultivar × storage, and cultivar × coating × storage interactions, demonstrated that early seedling performance was determined by the combined effects of genotype and seed-processing conditions (Table 1). In particular, coating reduced emergence speed from 94.15% in uncoated seeds to 66.43% in coated seeds, a reduction of approximately 29.44% and the most pronounced effect among the factors examined (Table 2). This reduction may be associated with restricted imbibition and oxygen diffusion caused by the coating material, increased physical resistance to radicle emergence, and delayed

leaching of germination inhibitors from the pericarp. Duan and Burris (1997) reported that film coating could delay germination in certain sugar beet genotypes, while Podlaski et al. (2019) demonstrated that pellet porosity, breaking force, water resistance, and water potential could determine germination and early seedling performance. Similarly, Kulan and Kaya (2016) found that uncoated sugar beet seeds could exhibit higher germination and emergence performance under laboratory conditions. These results indicate that, despite the technological advantages of coating, coating materials should be optimized to avoid restricting early seedling development.

The effect of coating on emergence speed varied among genotypes, demonstrating the biological significance of the cultivar × coating interaction. In uncoated seeds, emergence speed ranged from 90.33 to 97.67%, showing clear differences among cultivars, whereas in coated seeds the values narrowed to 64.58–68.33%, with all cultivars belonging to the same statistical group. The reduction associated with coating was limited to 25.09% in Juncal but reached 32.34% in Terranova, 31.47% in Preziosa, and 30.69% in Balboa (Table 2). These findings are noteworthy because coating not only reduced overall emergence speed but also largely suppressed the genotypic differences observed among uncoated seeds. Mirzaei and Hemayati (2022) reported that genotype and genotype × environment interactions significantly influenced germination characteristics in sugar beet, supporting a strong genotypic component in early seedling performance. Therefore, coating should not be assumed to produce similar physiological responses across all genotypes; instead, the structure and application characteristics of the coating material should be evaluated alongside the physiological characteristics of each cultivar.

Storage had a more limited effect on emergence speed than coating. The overall mean decreased from 81.53% before storage to 80.40% after storage and to 78.95% after transportation. Uncoated seeds largely maintained their pre-storage emergence speed of 96.35%, with values of 93.75% after storage and 92.35% after transportation, whereas coated seeds remained at approximately 65–67% throughout all stages. This indicates that coating, rather than storage, was the principal limitation on emergence speed. Nevertheless, within the cultivar × coating × storage interaction, emergence speed in uncoated Terranova seeds was 98.00% after transportation but fell to 60.25% in coated seeds at the same stage, showing that storage and transportation effects cannot be evaluated independently of coating and genotype (Table 2). Considering the physiological changes associated with storage and aging reported by Śliwińska (2003) and Gürel (2020), these findings indicate that the physical properties of coating materials, genotypic sensitivity, and storage/transportation conditions should be jointly optimized to maintain high emergence performance in sugar beet.

Emergence Percentage

The significant effects of coating, storage, and cultivar on emergence percentage, along with significant two-way and three-way interactions among these factors, showed that early seedling establishment in sugar beet was determined by the combined effects of genotype, seed-processing technology, and storage conditions (Table 1). Coating reduced emergence percentage from 96.22% in uncoated seeds to 76.12% in coated seeds, corresponding to a reduction of approximately 20.89% (Table 3). This pronounced reduction may be associated with restricted water uptake and oxygen diffusion caused by the coating material, increased mechanical resistance to radicle emergence, and delayed leaching of water-soluble inhibitors from the pericarp. Duan and Burris (1997) reported that polymer film coating could restrict germination, particularly in sensitive sugar beet genotypes, while Podlaski et al. (2019) demonstrated that pellet porosity, breaking force, water resistance, and water potential were important determinants of germination and early seedling performance. Similarly, Kulan and Kaya (2016) found that uncoated sugar beet seeds could exhibit higher germination and emergence performance than coated seeds. These findings indicate that, despite the commercial and agronomic advantages of coating, coating materials should be optimized to avoid restricting water–gas exchange and early seedling development.

The marked variation among cultivars in their response to coating demonstrated the importance of genotypic characteristics in maintaining emergence percentage. The coating-related reduction in emergence percentage reached 26.40% in Balboa and 25.26% in Preziosa, whereas the reduction was more limited in Terranova at 14.22%. Furthermore, Terranova maintained the highest emergence percentage in both uncoated (99.00%) and coated (84.92%) seeds, whereas Balboa exhibited the lowest performance under coated conditions at 70.17%. These differences demonstrate that the same coating treatment does not produce equivalent physiological responses across genotypes and that cultivar ×

coating compatibility is an important component of commercial seed quality (Table 3). Mirzaei and Hemayati (2022) reported that genotype and genotype × environment interactions significantly affected germination characteristics in sugar beet, while Podlaski and Chomontowski (2020) emphasized the importance of early germination and emergence performance for identifying differences in seed vigor. Therefore, the relatively high emergence percentage maintained by Terranova after coating, compared with the more pronounced losses observed in Balboa and Preziosa, indicates that coating formulations and application characteristics should be evaluated on a genotype-specific basis.

Table 3. Mean emergence percentage (%), number of normal seedlings, and number of dead seeds of sugar beet cultivars under different coating and storage stages, with statistical groupings.

[1]Means followed by the same letter are not significantly different.

Storage and transportation resulted in a more limited but gradual reduction in emergence percentage compared with the effect of coating. The overall mean decreased from 88.05% before storage to 85.80% after storage and further to 84.65% after transportation. In uncoated seeds, emergence decreased from 98.15% before storage to 94.40% after transportation, whereas in coated seeds it declined from 77.95% to 74.90% over the same period, with coated seeds consistently performing worse at all stages (Table 3). This trend is consistent with the physiological deterioration associated with storage and aging reported by Śliwińska (2003) and Gürel (2020). However, the significant cultivar × storage interaction indicated that genotypes responded differently to storage and transportation conditions. In particular, Terranova largely maintained its performance, whereas Juncal's emergence percentage decreased from 89.38% before storage to 80.63% after transportation. These findings demonstrate that maintaining a high emergence percentage in sugar beet depends not only on appropriate storage conditions but also on the combined management of coating material properties and genotypic sensitivity. In particular, cultivar × coating × storage/transportation compatibility should be considered a key optimization criterion for maintaining commercial seed quality.

Number of Normal Seedlings

Although cultivar, coating, and storage significantly affected the number of normal seedlings, the coating × storage and cultivar × coating interactions were not significant, indicating that genotypic differences and cultivar-specific responses to storage primarily determined this trait (Table 1). Coating increased the number of normal seedlings from 94.98 in uncoated seeds to 95.87 in coated seeds, corresponding to a limited increase of approximately 0.94%. This result indicates that coating did not have a pronounced adverse effect on the ability to produce normal seedlings and that initial seedling quality could be maintained under appropriate coating conditions (Table 3). Tohidloo et al. (2015) reported that appropriate seed-processing treatments could support normal seedling development in sugar beet and that treated seeds could maintain their performance after six months of storage, while Ignatz et al. (2019) demonstrated that reducing ABA, ions, and other inhibitory compounds in the pericarp could improve normal seedling development. Similarly, Capron et al. (2000) and Chomontowski et al. (2020) reported that appropriate priming treatments could promote germination and early seedling development, particularly in low-vigor seeds. Therefore, the effect of coating on normal seedling development should be evaluated not merely in terms of the presence or absence of a coating but also in relation to the initial physiological quality of the seeds and the characteristics of the seed-processing technology applied.

The pronounced differences among cultivars demonstrated the importance of genotypic effects on the ability to produce normal seedlings. Averaged across coating and storage stages, Preziosa and Terranova had the highest number of normal seedlings (97.75), followed by Gregoria and Juncal (96.63 and 96.00, respectively), whereas Balboa was clearly distinguished from the other cultivars with the lowest value (89.00). Accordingly, the number of normal seedlings in Preziosa and Terranova was approximately 9.83% higher than that in Balboa. In particular, coated Preziosa seeds exhibited high and stable performance, producing 97.75 normal seedlings before storage, 97.75 after storage, and 98.75 after transportation, indicating that this cultivar maintained a high degree of stability during seed processing, storage, and transportation. In contrast, the lower number of normal seedlings observed in Balboa across different coating and storage combinations suggests that initial seed vigor and genotypic characteristics may play a decisive role in normal seedling development (Table 3). The findings of Mirzaei and Hemayati (2022), who reported that genotypic differences significantly influenced early developmental characteristics in sugar beet, further support the present results. These findings indicate that commercial seed quality assessment should consider not only the overall effect of coating but also individual cultivars' ability to produce normal seedlings and maintain stable performance across treatments.

Regarding storage, the number of normal seedlings was 95.05 before storage, 95.48 after storage, and 95.75 after transportation, indicating that the capacity to produce normal seedlings was largely maintained throughout approximately six months of storage and the subsequent transportation period. However, significant cultivar × storage and cultivar × coating × storage interactions showed that this overall stability was not maintained equally across all genotypes. In the three-way interaction, the highest number of normal seedlings (99.00) was recorded for both uncoated and coated Terranova seeds before storage, whereas the lowest value (86.75) was observed in uncoated Balboa seeds before storage. Furthermore, Preziosa and Terranova largely maintained their high capacity to produce normal seedlings

across different treatment combinations (Table 3). When considered together with the differences related to genotype, initial physiological quality, and storage stability reported by Śliwińska (2003), Tohidloo et al. (2015), and Podlaski and Chomontowski (2020), the present results indicate that coating and storage conditions should be evaluated in conjunction with genotypic seed vigor to maintain a high capacity for normal seedling development in sugar beet. Moreover, cultivar stability during storage and transportation should be considered an important selection criterion for commercial seed quality.

Number of Dead Seeds

Although cultivar, coating, and storage significantly affected the number of dead seeds, the coating × storage and cultivar × coating interactions were not significant, indicating that genotypic differences and cultivar-specific responses to storage largely determined this trait (Table 1). The decrease in dead seeds from 4.98 in uncoated seeds to 4.13 in coated seeds, a reduction of approximately 17.07%, suggests that coating did not adversely affect seed viability and, under appropriate conditions, may help maintain it (Table 3). Tohidloo et al. (2015) reported that appropriate seed-processing treatments could contribute to maintaining germination performance and normal seedling development in sugar beet, while Ignatz et al. (2019) demonstrated that reducing ABA, ions, and other inhibitory compounds present in the pericarp could improve germination performance. Similarly, Capron et al. (2000) and Chomontowski et al. (2020) reported that appropriate priming treatments could support seed viability and early developmental performance, particularly in low-vigor seeds. These findings indicate that the effect of coating on the number of dead seeds should be evaluated not only in terms of the coating treatment itself but also in relation to initial seed quality, coating material characteristics, and the seed's physiological response following processing.

The wide variation among cultivars clearly demonstrated the importance of genotypic effects in determining the number of dead seeds. Averaged across coating treatments and storage stages, Balboa had the highest number of dead seeds at 10.92, whereas Juncal and Gregoria showed intermediate values of 4.00 and 3.38, respectively, and Preziosa and Terranova had the lowest values at 2.25. Thus, the number of dead seeds in Balboa was approximately 4.85 times higher than that in Preziosa and Terranova. While Balboa maintained a relatively high number of dead seeds under both uncoated and coated conditions, the number decreased to as low as 1.25 in coated Preziosa seeds after transportation, indicating a strong genotype-dependent response to coating and processing conditions (Table 3). The findings of Mirzaei and Hemayati (2022), who reported significant effects of genotype and genotype × environment interactions on germination characteristics in sugar beet, and those of Podlaski and Chomontowski (2020), who emphasized initial seed vigor as a major determinant of subsequent performance, support the present results. Therefore, reducing the number of dead seeds in commercial sugar beet seed lots requires considering not only coating technology but also genotypic viability potential and initial seed quality as key selection criteria.

For storage and transportation, the number of dead seeds decreased from 4.93 before storage to 4.50 after storage and further to 4.25 after transportation, indicating that approximately six months of storage followed by transportation did not increase seed mortality under the conditions of the present experiment. However, the significant cultivar × storage and cultivar × coating × storage interactions demonstrated that this overall trend was not consistent across all genotypes. Balboa maintained a relatively high number of dead seeds at all stages, whereas Preziosa decreased to 1.63 after transportation. In the three-way interaction, values ranged from 1.00 to 13.00, with the highest value observed in the uncoated Balboa × before-storage combination and the lowest values recorded in both uncoated and coated Terranova × before-storage combinations (Table 3). Reports by Śliwińska (2003), Gürel (2020), and Tohidloo et al. (2015) indicate that storage performance depends on initial physiological quality, genotype, and storage conditions, supporting this variation. Overall, maintaining a low number of dead seeds and preserving seed viability during storage and transportation in sugar beet requires considering initial seed quality and the storage stability of individual cultivars, while coating and storage protocols should be optimized according to genotype-specific responses.

CONCLUSION

This study showed that the effects of seed coating, storage, and transportation on germination and early seedling performance in sugar beet varied considerably by genotype and trait. Coating reduced germination speed from 85.67% to 69.92%, final germination percentage from 95.62% to 78.93%,

emergence speed from 94.15% to 66.43%, and final emergence percentage from 96.22% to 76.12%, indicating a pronounced limitation of germination and emergence performance. In contrast, coating increased the number of normal seedlings from 94.98 to 95.87 and reduced the number of dead seeds from 4.98 to 4.13. Significant differences were also observed among cultivars. Terranova showed high final germination and final emergence percentages, whereas Preziosa and Terranova had high numbers of normal seedlings and low numbers of dead seeds. In contrast, Balboa generally showed lower germination performance and seed viability.

Although storage and transportation affected the traits differently, the larger reductions in germination-related traits in coated seeds, along with significant cultivar × coating × storage/transportation interactions, showed that these processes should not be evaluated independently of genotype. Overall, the results indicate that commercial sugar beet seed production should prioritize cultivar × coating compatibility rather than relying on a uniform coating strategy. Furthermore, coating materials should be optimized to minimize restrictions on water uptake and gas exchange, while storage and transportation conditions should be managed according to genotype-specific sensitivity. Such an integrated approach is critical for maintaining high germination performance and seed quality until sowing.

ABSTRACT
Rapid, balanced seedling development is critical for uniform crop establishment and maintaining yield potential in sugar beet. This study aimed to determine the effects of seed coating, storage, and transportation processes on early seedling growth traits in different sugar beet cultivars. Uncoated and coated seeds of Balboa, Gregoria, Juncal, Preziosa, and Terranova were evaluated before storage, after about six months of storage at 5 °C and 60% relative humidity, and after a subsequent 16-h transportation period. Seedling length, root length, vegetative fresh and dry weight, and root fresh and dry weight were assessed. The results demonstrated that seed coating, storage/transportation stage, cultivar, and their interactions markedly influenced early seedling development, with responses varying among genotypes. Mean seedling length increased from 5.75 cm in uncoated seeds to 5.92 cm in coated seeds, while the highest overall seedling length was recorded after transportation at 6.03 cm. In contrast, root length decreased from 9.03 cm in uncoated seeds to 8.15 cm following coating. Vegetative fresh weight increased from 0.317 to 0.331 g, whereas vegetative dry weight increased from 0.019 to 0.021 g. Cultivar-specific responses to coating were pronounced; Terranova and Juncal showed particularly positive responses in vegetative dry matter accumulation. Conversely, root dry weight declined from 0.021 g in uncoated seeds to 0.018 g in coated seeds. Overall, seed coating may promote shoot elongation and vegetative biomass accumulation while simultaneously restricting root development, and the magnitude and direction of these responses depend strongly on cultivar and post-coating storage conditions. Therefore, seed coating and storage protocols should be optimized on a genotype-specific basis to maintain vigorous and balanced early seedling development in commercial sugar beet seed production.
Keywords: Root Growth, Seed Coating, Seedling Development, Storage, Transportation.

INTRODUCTION
Sugar beet (*Beta vulgaris* L.) is a principal raw material of the sugar industry and a strategically important industrial crop in many countries because of its high economic value. Achieving high yield and quality in sugar beet production depends on the rapid establishment of a uniform crop stand after sowing and the maintenance of an optimum plant population per unit area (Kockelmann and Meyer, 2006; Kockelmann et al., 2010). Because irregular emergence and seedling losses occurring during the early stages of plant development cannot be adequately compensated for at later growth stages, the ability of seeds to produce vigorous and uniform seedlings is critical for successful crop establishment (Kulan and Kaya, 2016; Podlaski and Chomontowski, 2020). Therefore, seed quality assessment should not rely solely on final germination percentage but should also consider early developmental traits such as seedling and root growth, biomass accumulation, and the capacity to produce normal seedlings. Indeed, high seed vigor has been associated with rapid and uniform emergence, vigorous seedling development, and greater tolerance to environmental stress conditions (Finch-Savage and Bassel, 2016; Ma et al., 2022).
Early seedling performance depends on the combined effects of numerous factors, including genetic background, environmental conditions during seed development and maturation, harvest timing, initial physiological quality, seed processing treatments, and storage conditions (Finch-Savage and Bassel, 2016; Leprince et al., 2016).

Environmental conditions experienced during seed development and maturation may affect not only germination capacity but also seed vigor and subsequent seedling development (Mirzaei and Hemayati, 2022). In sugar beet, harvest maturity and seed moisture content are important determinants of physiological seed quality and storability, whereas unfavorable conditions may accelerate losses in viability and vigor (Śliwińska et al., 1999; Śliwińska, 2003). In particular, physiological aging during storage may reduce seed vigor before a pronounced decline in germination becomes apparent, making early seedling growth traits valuable indicators of changes in seed quality (Walters et al., 2005; Solberg et al., 2020; Zinsmeister et al., 2020). Accordingly, traits such as seedling length, root length, fresh and dry biomass accumulation, and normal seedling formation represent important physiological criteria for assessing the effects of storage and other post-processing operations on seed performance.

A substantial proportion of commercial seeds used in modern sugar beet production undergo coating or pelleting to improve their physical characteristics for precision sowing and to facilitate the application of various active ingredients to the seed surface. Seed-coating technologies give irregularly shaped sugar beet seeds more standardized size and shape, facilitating precision sowing while enabling controlled, uniform delivery of protective compounds, nutrients, and biostimulants (Rocha et al., 2019; Afzal et al., 2020). However, the effects of coating on early seedling development may vary depending on the physical and physicochemical properties of the filler and binder materials used. Excessive mechanical resistance of the coating layer or insufficient porosity may restrict water and oxygen uptake, thereby adversely affecting radicle emergence and subsequent root and shoot development (Afzal et al., 2020; Ma et al., 2022). Considering that the structural characteristics of the pericarp and the presence of germination-inhibiting compounds, including phenolic compounds, abscisic acid, and various ions, may also influence germination in sugar beet seeds, interactions between the coating material and the seed may be particularly important in determining early seedling development (Duan and Burris, 1997; Ignatz et al., 2019).

The ability of coated seeds to maintain physiological quality until sowing depends not only on the coating treatment but also on the conditions encountered during storage and transportation. Temperature, relative humidity, and seed moisture content are among the major factors determining the rate of seed aging during storage. High temperature and humidity accelerate physiological deterioration, whereas appropriate storage conditions maintain seed viability and vigor for longer periods (Walters et al., 2005; Gürel, 2020; Solberg et al., 2020). In coated seeds, the coating material's physical integrity must also be maintained. Binder and filler materials used in coating formulations, together with drying conditions, may affect the mechanical strength, porosity, water permeability, and disintegration behavior of the pellet, and changes in these properties may subsequently influence seedling development (Afzal et al., 2020; Paravar et al., 2023; Köhl et al., 2024). Furthermore, vibration, friction, and other mechanical forces during transportation may cause abrasion, cracking, or fragmentation of the coating surface, potentially altering seed physiological performance at sowing after storage and transportation. Evidence that differences in pellet breaking strength, abrasion resistance, water resistance, and porosity can influence sugar beet seed performance, particularly under suboptimal moisture conditions, further highlights the importance of evaluating coating, storage, and transportation processes in an integrated manner (Podlaski et al., 2019).

Previous studies on sugar beet have separately investigated the effects of coating and pelleting characteristics, priming, polishing and washing treatments, and storage conditions on seed germination, emergence, and seedling development (Duan and Burris, 1997; Capron et al., 2000; Marcinek et al., 2011; Ignatz et al., 2019; Podlaski et al., 2019; Chomontowski et al., 2020; Gürel, 2020). However, studies simultaneously evaluating the sequential effects of seed coating, storage, and transportation on early seedling growth traits across different sugar beet cultivars remain limited. Moreover, because genotypic differences may result in cultivar-specific physiological responses to these processes, coating and storage/transportation treatments should be evaluated at the cultivar level. Therefore, the present study aimed to compare the early seedling growth performance of uncoated and coated seeds of different sugar beet cultivars before storage, after storage, and after storage plus transportation by evaluating seedling length, root length, vegetative fresh and dry weight, and root fresh and dry weight. The study further aimed to elucidate cultivar × coating × storage/transportation interactions affecting early seedling development and to provide a scientific basis for storage and logistical practices designed to maintain the physiological quality of commercial sugar beet seeds until sowing.

MATERIALS AND METHODS

Plant Material

This study was conducted during 2024–2025 in the laboratories of the Ankara Seed Registration and Certification Directorate to determine the physiological quality and early seedling growth performance of uncoated and coated sugar beet (*Beta vulgaris* L.) seeds before storage, after storage, and after storage plus transportation. Seeds of five sugar beet cultivars, Balboa, Gregoria, Juncal, Preziosa, and Terranova, were used as plant material. To allow direct comparison of coating treatments, seeds from the same seed lot of each cultivar were divided into two groups: coated and uncoated. Seed coating was performed by ABEL Ziraat A.Ş. at a coating ratio of 1:1 (w/w), corresponding to the application of 1 kg of coating material per 1 kg of seed. The cultivars used in the study differed in their agronomic characteristics and disease tolerance. Balboa is characterized by its monogerm, root-sugar type and tolerance to *Rhizomania*; Gregoria by high resistance to *Rhizomania* and tolerance to *Cercospora* leaf spot and powdery mildew; Juncal by its monogerm, root-sugar type, *Fusarium* tolerance, and suitability for early sowing; Preziosa by high resistance to *Rhizomania* and tolerance to cyst nematode and *Cercospora* leaf spot; and Terranova by high resistance to *Rhizomania* and tolerance to *Cercospora* leaf spot and powdery mildew. Furthermore, Balboa and Juncal achieved mean root yields of 8.88 and 7.87 t ha^{-1}, respectively, in registration trials, with sugar contents of 17.10% and 15.35%, respectively. Thus, cultivars with contrasting genetic and agronomic characteristics enabled comparison of cultivar-specific responses to coating, storage, and transportation.

Methods

Seed Physiological Quality Before Storage

To determine physiological quality before storage, seeds obtained from harvested plants that had not yet been subjected to any storage or transportation process were used. Standard germination tests were conducted in accordance with the rules of the International Seed Testing Association (ISTA) to determine the initial physiological quality of the seeds. Seedling length, root length, and fresh and dry biomass accumulation were determined. These values served as baseline data for evaluating changes after storage and transportation (ISTA, 2025).

Seed Physiological Quality After Storage

To determine the effects of storage on seed physiological quality and early seedling development, seeds were stored for approximately six months at +5 °C and 60% relative humidity. Following completion of the storage period, physiological seed quality was reassessed in accordance with ISTA rules. Standard germination tests were conducted, and seedling length, root length, and fresh and dry biomass accumulation were determined. The results were compared with the pre-storage values to assess the effects of the six-month storage period on seed physiological quality and early seedling development (ISTA, 2025).

Seed Physiological Quality After Storage and Transportation

To determine the effects of post-storage transportation on seed performance, seeds stored for approximately six months at +5 °C and 60% relative humidity underwent a 16-h transportation period. Following transportation, seed physiological quality and early seedling growth performance were evaluated in accordance with ISTA rules. Seedling length, root length, and fresh and dry biomass accumulation were determined. The resulting data were compared with those obtained before and after storage to evaluate the sequential effects of storage and subsequent transportation on seed physiological quality and early seedling development (ISTA, 2025).

Statistical Analysis

Data from the study were analyzed using analysis of variance (ANOVA) in JMP statistical software. When ANOVA detected significant effects, treatment means were compared using Tukey's Honestly Significant Difference (HSD) multiple-comparison test in JMP (JMP, 2023). Statistical significance was evaluated at the 5% probability level ($p < 0.05$), and differences among means were indicated by letter groupings.

RESULTS AND DISCUSSION

Seedling Length

The significant effects of coating, storage, and cultivar on seedling length, together with the significant coating × storage, cultivar × coating, and cultivar × storage × coating interactions, indicate that early seedling development in sugar beet is jointly influenced by genotype and seed processing conditions (Table 1). Overall, coating increased seedling length from 5.75 cm in uncoated seeds to 5.92 cm in coated seeds, corresponding to an increase of approximately 2.96%. In coated seeds, seedling length increased from 5.47 cm before storage to 6.32 cm after transportation. In contrast to the adverse effects of coating previously observed for germination and emergence traits, these findings suggest that, although coating may delay initial development under certain conditions, it may subsequently promote seedling elongation (Table 2). Similarly, Chomontowski et al. (2020) reported that appropriate priming treatments could promote early plant development, while Capron et al. (2000) demonstrated that hydropriming and osmopriming could improve germination and early growth performance in sugar beet. Ignatz et al. (2019) further showed that reducing ABA and other inhibitory compounds in the pericarp could facilitate faster and more normal seedling development. Therefore, the effects of coating on seedling development should be evaluated not only for potential delays during germination but also for post-germination growth dynamics.

The direction and magnitude of seedling growth responses to coating differed among cultivars, clearly demonstrating the importance of the cultivar × coating interaction. Coating increased seedling length by 18.64% in Balboa, 7.48% in Gregoria, and 3.43% in Juncal, whereas it decreased seedling length by 9.08% in Preziosa and 2.90% in Terranova. Particularly noteworthy was Balboa, which showed one of the lowest seedling lengths under the uncoated treatment (5.31 cm) but reached 6.30 cm after coating, one of the highest values among the cultivars. In contrast, Preziosa, which exhibited the greatest seedling length under the uncoated treatment (6.28 cm), decreased to 5.71 cm following coating. These contrasting responses demonstrate that the same coating treatment may induce opposite growth responses depending on the cultivar (Table 2). The findings of Mirzaei and Hemayati (2022), who reported significant effects of genotype and genotype × environment interactions on early growth traits in sugar beet, are consistent with this genotypic differentiation. Collectively, these findings suggest that the effectiveness of coating in promoting early seedling development depends not only on coating material characteristics but also on the genotype's physiological response to the microenvironment created by the coating. Therefore, evaluate coating × genotype compatibility on a cultivar-specific basis.

Across storage stages, seedling length increased from 5.64 cm before storage to 5.84 cm after storage and 6.03 cm after transportation, representing a response that differed from the declining trend previously observed for germination and emergence traits. This increase was particularly pronounced in coated seeds, in which seedling length increased from 5.47 cm before storage to 6.32 cm after transportation, whereas uncoated seeds showed relatively little variation, remaining within approximately 5.70–5.82 cm. However, rather than interpreting this increase as a direct physiological benefit of storage, it is more appropriate to consider it in the context of the coating × storage interaction and genotype-specific growth responses. Indeed, the highest seedling length was recorded for coated Gregoria after transportation (6.91 cm), whereas the lowest value was observed for uncoated Balboa after storage (5.10 cm), highlighting the biological relevance of the three-way interaction (Table 2). Overall, although seed coating can increase seedling length in sugar beet, the dependence of this response on cultivar and storage/transportation stage indicates that coating technologies should be optimized on a cultivar-specific basis to improve early seedling development.

Root Length

The significant effects of the main factors of coating, storage, and cultivar, together with all two-way and three-way interactions, on root length indicate that root development in sugar beet is jointly influenced by genotype, seed processing technology, and storage conditions (Table 1). Seed coating reduced root length from 9.03 cm in uncoated seeds to 8.15 cm in coated seeds, corresponding to a decrease of approximately 9.75% (Table 2). This reduction may reflect coating-induced changes in imbibition and oxygen diffusion, the physical resistance the coating layer imposes on radicle emergence, and the resulting restriction of early root elongation. Duan and Burris (1997) reported that seed coating in sugar beet could influence germination and early development by modifying the movement of water, oxygen, and inhibitory compounds, while Podlaski et al. (2019) demonstrated that pellet porosity,

mechanical strength, water resistance, and water potential are important determinants of early developmental performance. The higher germination and emergence performance reported for uncoated sugar beet seeds by Kulan and Kaya (2016) is also consistent with the present findings. Collectively, these results indicate that coating materials should be optimized not only for germination and emergence but also to avoid restricting early root system development.

Root Length

The significant effects of the main factors of coating, storage, and cultivar, together with all two-way and three-way interactions, on root length indicate that root development in sugar beet is jointly influenced by genotype, seed processing technology, and storage conditions (Table 1). Seed coating reduced root length from 9.03 cm in uncoated seeds to 8.15 cm in coated seeds, corresponding to a decrease of approximately 9.75% (Table 2). This reduction may reflect coating-induced changes in imbibition and oxygen diffusion, the physical resistance the coating layer imposes on radicle emergence, and the resulting restriction of early root elongation. Duan and Burris (1997) reported that seed coating in sugar beet could influence germination and early development by modifying the movement of water, oxygen, and inhibitory compounds, while Podlaski et al. (2019) demonstrated that pellet porosity, mechanical strength, water resistance, and water potential are important determinants of early developmental performance. The higher germination and emergence performance reported for uncoated sugar beet seeds by Kulan and Kaya (2016) is also consistent with the present findings. Collectively, these results indicate that coating materials should be optimized not only for germination and emergence but also to avoid restricting early root system development.

The effect of coating on root development varied markedly among cultivars, demonstrating the biological importance of the cultivar × coating interaction. Coating-induced reductions in root length were limited to 3.31% in Juncal and 4.11% in Gregoria, whereas the corresponding reductions reached 15.27% in Terranova and 14.39% in Preziosa. Nevertheless, when averaged across treatments, Preziosa (9.09 cm) and Balboa (9.00 cm) recorded the greatest root lengths, whereas Gregoria, Juncal, and Terranova showed lower and statistically similar values. These differences indicate that a genotype with

inherently high root growth potential may not maintain the same advantage after coating, and that tolerance to coating should therefore be evaluated independently of initial root growth capacity (Table 2). This interpretation is consistent with Mirzaei and Hemayati (2022), who reported that genotype and genotype × environment interactions significantly influenced early growth traits in sugar beet. Therefore, rather than adopting a uniform coating strategy, cultivar-specific optimization approaches that account for genotypic differences in physiological sensitivity to coating appear to be more appropriate.

Table 2. Mean seedling length (cm), root length (cm), and vegetative fresh weight (g) of sugar beet cultivars under different coating treatments and storage stages, with statistical groupings

Coating	Storage	Cultivars					Mean

[1]Means followed by the same letter are not significantly different.

Storage and transportation also adversely affected root development, with mean root length decreasing from 8.79 cm before storage to 8.51 cm after storage and 8.46 cm after transportation. However, the coating × storage interaction indicated that this reduction was more pronounced in coated seeds. After transportation, root length decreased by only 1.09% in uncoated seeds, whereas it fell by 6.67% in coated seeds. Within the three-way interaction, uncoated Preziosa exhibited the greatest root length after transportation (10.53 cm), whereas coated Balboa showed the lowest value at the same stage (6.73 cm), clearly demonstrating that the effect of transportation varied substantially depending on both coating treatment and cultivar (Table 2). Taken together with the storage-related losses in physiological seed quality reported by Śliwińska (2003) and Gürel (2020), these findings suggest that maintaining root development in sugar beet requires integrated optimization of coating material physical properties, genotypic sensitivity, and storage/transportation conditions. In particular, post-transportation performance of coated seeds may represent an important criterion when evaluating seed quality for commercial use.

Vegetative Fresh Weight

The significant effects of coating, storage, and cultivar, together with all two-way and three-way interactions, on vegetative fresh weight indicate that seedling biomass accumulation in sugar beet is jointly influenced by genotype, seed processing treatment, and storage conditions (Table 1). Seed coating increased vegetative fresh weight from 0.317 g in uncoated seeds to 0.331 g in coated seeds, corresponding to an increase of approximately 4.42%. Despite the reductions previously observed in germination and emergence traits, this response suggests that coating may promote biomass accumulation in seedlings that successfully continue their development (Table 2). This finding is consistent with previous studies reporting beneficial effects of appropriate seed treatments on post-germination seedling development. Chomontowski et al. (2020) reported that appropriate priming treatments could enhance early seedling development and biomass accumulation, particularly in low-vigor sugar beet seeds, while Capron et al. (2000) demonstrated that hydropriming and osmopriming could improve early growth performance. Similarly, Ignatz et al. (2019) reported that reducing ABA and other inhibitory compounds in the pericarp promoted normal seedling development, whereas Podlaski et al. (2019) emphasized that porosity, water potential, and other physical properties of coating materials are important determinants of early seedling performance. Therefore, the effects of coating on seedling biomass should be evaluated not merely in terms of the presence or absence of a coating layer but also in relation to the physical properties of the coating material and the physiological response of the seed following coating.

The effect of coating on vegetative fresh weight varied markedly among cultivars in both magnitude and direction. Coating increased vegetative fresh weight by approximately 23.55% in Balboa and 18.37% in Juncal, whereas reductions of 0.58%, 9.28%, and 3.27% were observed in Gregoria, Preziosa, and Terranova, respectively. In particular, vegetative fresh weight in Balboa increased from 0.276 g in uncoated seeds to 0.341 g in coated seeds, indicating a strong positive biomass response to coating in this cultivar. In contrast, the decrease from 0.345 to 0.313 g in Preziosa demonstrates that the same coating treatment may produce contrasting responses among genotypes (Table 2). Across cultivars, Gregoria had the highest mean vegetative fresh weight (0.343 g), whereas Balboa and Juncal had the lowest mean values (0.309 g). The findings of Mirzaei and Hemayati (2022), who reported significant effects of genotype and genotype × environment interactions on early growth traits in sugar beet, are consistent with this cultivar-dependent variation. These results indicate that the effect of coating on biomass accumulation is genotype-specific and that cultivar × coating compatibility should be a key optimization criterion in commercial seed-coating applications.

Storage and transportation did not reduce vegetative fresh weight; instead, the overall mean increased from 0.319 g before storage to 0.325 g after storage and 0.328 g after transportation. This trend was particularly evident in coated seeds, for which vegetative fresh weight increased from 0.323 g before storage to 0.336 g after storage and remained at 0.335 g after transportation, whereas uncoated seeds showed no statistically significant change among storage stages. However, rather than interpreting this increase as a direct stimulatory effect of storage, it is more appropriate to consider it as the outcome of the combined effects of coating, genotype, and storage stage. Indeed, within the three-way interaction, uncoated Terranova recorded the highest vegetative fresh weight after transportation (0.361 g), whereas uncoated Balboa showed the lowest value after storage (0.264 g), clearly demonstrating the importance

of genotype-specific responses (Table 2). Overall, the response of vegetative fresh biomass to coating and storage/transportation processes in sugar beet varied substantially among cultivars, indicating that coating materials, cultivar characteristics, and storage conditions should be considered together when developing strategies to optimize early seedling growth.

Vegetative Dry Weight

Although vegetative dry weight was significantly affected by coating and cultivar, the nonsignificant main effect of storage indicates that dry matter accumulation in sugar beet was influenced more strongly by genotype and seed processing treatment than by storage stage itself (Table 1). Seed coating increased vegetative dry weight from 0.019 g in uncoated seeds to 0.021 g in coated seeds, corresponding to an increase of approximately 10.53%, suggesting that coating may promote seedling dry matter accumulation under appropriate conditions (Table 3). Capron et al. (2000) and Chomontowski et al. (2020) reported that appropriate seed treatments and priming techniques could improve early seedling development and biomass accumulation in sugar beet, while Ignatz et al. (2019) demonstrated that reducing ABA and other inhibitory compounds in the pericarp could promote normal seedling development. Similarly, Podlaski et al. (2019) reported that the porosity, water potential, and other physical properties of coating materials may influence post-germination seedling performance. These findings indicate that the effects of coating on early development should not be evaluated solely on the basis of germination or emergence performance; post-germination dry matter accumulation should also be considered.

The effect of coating on vegetative dry weight differed among cultivars in both direction and magnitude, clearly demonstrating the importance of the cultivar × coating interaction. Coating increased vegetative dry weight by approximately 33.33% in Juncal and 73.33% in Terranova, whereas reductions of 25.00% and 9.09% were observed in Balboa and Preziosa, respectively; no appreciable change occurred in Gregoria. Particularly, vegetative dry weight in Terranova increased from 0.015 g in uncoated seeds to 0.026 g in coated seeds, indicating a strong positive response to coating in terms of dry matter accumulation. In contrast, the reduction from 0.024 to 0.018 g in Balboa suggests that coating may induce contrasting physiological responses by genotype (Table 3). The findings of Duan and Burris (1997), who reported that responses to coating treatments may vary among sugar beet genotypes and seed lots, together with those of Mirzaei and Hemayati (2022), who emphasized genotypic variation in early growth traits, are consistent with the present results. Therefore, rather than adopting a uniform coating approach to improve vegetative dry matter accumulation, cultivar-specific strategies that account for individual genotypes' physiological responses to coating appear more appropriate.

Although the main effect of storage on vegetative dry weight was not statistically significant, the significant cultivar × storage and cultivar × coating × storage interactions indicate that the response to storage cannot be evaluated independently of cultivar and coating status. Mean vegetative dry weight increased from 0.019 g before storage to 0.021 g after storage and subsequently returned to 0.019 g after transportation, suggesting that storage and transportation did not result in an overall and persistent reduction in dry matter accumulation. However, coated Terranova reached 0.031 g after storage, the highest value among all treatment combinations, and coated Juncal reached 0.026 g, whereas coated Balboa exhibited the lowest value at the same stage (0.014 g). These contrasting responses demonstrate that the effect of storage was strongly dependent on the specific cultivar × coating combination (Table 3). Śliwińska (2003) reported that responses to storage and seed aging depend on initial seed quality, while Tohidloo et al. (2015) indicated that appropriately processed sugar beet seeds may retain their seedling establishment performance after storage, supporting the cultivar- and treatment-dependent variation observed in the present study. Overall, maintaining or enhancing vegetative dry matter accumulation in sugar beet requires the integrated consideration of coating material properties, genotypic responses, and storage conditions, emphasizing the importance of cultivar-specific optimization of seed-coating technologies.

Root Fresh Weight

The significant effects of coating, storage, and cultivar, together with all two-way and three-way interactions, on root fresh weight indicate that root biomass accumulation in sugar beet is jointly influenced by genotype, seed processing treatment, and storage conditions (Table 1). Seed coating increased root fresh weight from 0.082 g in uncoated seeds to 0.091 g in coated seeds, corresponding to an increase of approximately 10.98%. Despite the restrictive effects of coating previously observed for

germination and emergence traits, this increase suggests that coating may promote root biomass accumulation in seedlings that continue developing successfully (Table 3). Capron et al. (2000) and Chomontowski et al. (2020) reported that appropriate seed treatments and priming techniques could promote early seedling development in sugar beet, while Ignatz et al. (2019) demonstrated that reducing ABA and other inhibitory compounds in the pericarp could improve normal seedling development. Similarly, Podlaski et al. (2019) reported that porosity, water potential, and other physical properties of coating materials may be important determinants of post-germination seedling development. These findings indicate that coating effects on root development should be evaluated not only in terms of root length but also in relation to root biomass accumulation.

Although coating increased root fresh weight in all cultivars, the magnitude of this response varied considerably among genotypes. Following coating, root fresh weight increased by 11.25% in Balboa, 6.98% in Gregoria, 3.57% in Juncal, and 2.17% in Preziosa, whereas the increase reached 34.33% in Terranova. In particular, Terranova, which had the lowest root fresh weight in uncoated seeds (0.067 g), increased to 0.090 g after coating, indicating a strong positive response to coating in root biomass accumulation. Nevertheless, across overall cultivar means, Preziosa had the highest root fresh weight (0.093 g), whereas Terranova had the lowest (0.079 g) (Table 3). The findings of Duan and Burris (1997), who reported that responses to coating treatments may vary among sugar beet genotypes and seed lots, together with those of Mirzaei and Hemayati (2022), who emphasized genotypic differences in early growth traits, are consistent with the present results. Therefore, in addition to the overall effect of coating, consider cultivar × coating compatibility when seeking to improve root biomass accumulation, and optimize coating treatments according to genotype-specific responses.

Table 3. Mean vegetative dry weight (g), root fresh weight (g), and root dry weight (g) of sugar beet cultivars under different coating treatments and storage stages, with statistical groupings

[1]Means followed by the same letter are not significantly different.

Storage and transportation reduced root fresh weight, with the overall mean decreasing from 0.092 g before storage to 0.086 g after storage and 0.081 g after transportation, corresponding to reductions of approximately 6.52% and 11.96%, respectively, relative to the pre-storage value. However, this reduction was more pronounced in uncoated seeds, in which root fresh weight decreased from 0.090 g before storage to 0.071 g after transportation, whereas coated seeds exhibited only a limited decrease from 0.094 to 0.090 g. This pattern suggests that coating may help maintain root biomass during storage and transportation. Nevertheless, in the three-way interaction, coated Preziosa showed the highest root fresh weight after transportation (0.111 g), whereas uncoated Terranova showed the lowest value at the same stage (0.015 g), demonstrating that the apparent protective effect of coating was strongly genotype-dependent (Table 3). Together with the storage-related physiological changes reported by Śliwińska (2003) and Gürel (2020), these findings indicate that maintaining and improving root fresh biomass in sugar beet requires integrated consideration of coating material properties, genotypic sensitivity, and storage/transportation conditions. In particular, consider cultivar × coating compatibility when evaluating seed performance after transportation.

Root Dry Weight

The significant effects of coating, storage, and cultivar, together with all two-way and three-way interactions, on root dry weight indicate that root dry matter accumulation in sugar beet is jointly influenced by genotype, seed processing treatment, and storage conditions (Table 1). Seed coating reduced root dry weight from 0.021 g in uncoated seeds to 0.018 g in coated seeds, corresponding to a decrease of approximately 14.29%. This reduction may reflect coating-induced changes in imbibition, oxygen diffusion, and radicle development, which could limit root dry matter accumulation during early seedling growth (Table 3). Duan and Burris (1997) reported that coating may alter the movement of water, oxygen, and inhibitory compounds in sugar beet seeds, while Podlaski et al. (2019) demonstrated that pellet porosity, water resistance, and water potential are important determinants of early seedling performance. In contrast, Capron et al. (2000) and Chomontowski et al. (2020) reported that appropriate seed treatments and priming techniques could promote early seedling development and biomass accumulation. These contrasting findings indicate that the effects of coating on root dry matter accumulation should be interpreted in relation to both the coating's physical characteristics and the genotype's physiological response.

The direction and magnitude of the response to coating varied among cultivars, demonstrating that the cultivar × coating interaction was an important determinant of root dry weight. Coating reduced root dry weight by approximately 58.97% in Balboa, whereas Gregoria, Preziosa, and Terranova showed increases of 37.50%, 12.50%, and 13.33%, respectively; Juncal showed no appreciable change. In particular, Balboa showed the highest root dry weight under the uncoated treatment (0.039 g), but it decreased to 0.016 g after coating, indicating a strong negative response to coating. In contrast, the increase from 0.016 to 0.022 g in Gregoria suggests that coating may promote root dry matter accumulation in some genotypes (Table 3). The findings of Mirzaei and Hemayati (2022), who reported that early growth traits in sugar beet were significantly influenced by genotype and genotype × environment interactions, are consistent with this cultivar-dependent variation. Therefore, when the objective is to maintain root dry matter accumulation, coating treatments should not be evaluated

independently of genotype, and cultivar × coating compatibility should be considered an important selection criterion in seed processing strategies.

Although overall root dry weight was 0.016 g before storage and 0.017 g after storage and increased to 0.024 g after transportation, the interaction results indicate that this increase was largely attributable to a specific cultivar × treatment combination rather than to a general beneficial effect of transportation. In uncoated Balboa, root dry weight increased from 0.016 g before storage and 0.017 g after storage to 0.084 g after transportation. In contrast, values for coated Balboa remained within a narrow range of 0.015–0.017 g across all stages, while changes in the other cultivars were generally limited. Therefore, the approximately 50% increase in the overall mean observed after transportation should be interpreted as a strong response specific to the Balboa × uncoated × transportation combination rather than as a general transportation effect applicable to all cultivars (Table 3). The genotype-, initial seed quality-, and seed processing-dependent responses to storage reported by Śliwińska (2003), Tohidloo et al. (2015), and Kulan and Kaya (2016) support this interpretation. Overall, evaluating root dry weight in sugar beet should not rely solely on main-effect means; cultivar × coating × storage interactions should also be considered, and unusually strong genotype-specific responses should be distinguished from general treatment trends.

CONCLUSION

This study showed that the effects of seed coating, storage, and transportation on early seedling development in sugar beet varied substantially by trait and cultivar. Overall, seed coating increased seedling length and vegetative fresh and dry weight, while reducing root length and root dry weight; in contrast, root fresh weight increased following coating, indicating contrasting responses among different components of shoot and root development. The marked differences in coating responses among Balboa, Gregoria, Juncal, Preziosa, and Terranova, along with the significance of numerous cultivar × coating × storage/transportation interactions, indicate that a uniform coating and storage strategy may not suit all cultivars equally. Storage and transportation also affected the evaluated traits differently. Reductions were particularly evident in root length and root fresh weight, whereas some biomass traits were maintained or increased depending on cultivar and coating status. Overall, maintaining high and balanced early seedling performance in commercial sugar beet seeds requires cultivar-specific optimization of the physical and physiological properties of coating materials, management of storage and transportation conditions with consideration of cultivar × coating interactions, and an integrated assessment of shoot growth, root development, and biomass accumulation rather than reliance on a single growth trait.

ABSTRACT
Rapid, balanced seedling development is critical for uniform stand establishment and successful crop establishment in alfalfa. This study aimed to determine the effects of seed coating, storage, and transfer processes on early seedling development and biomass traits in different alfalfa cultivars. Uncoated and coated seeds prepared at a 1:1 coating ratio from five cultivars, Bilensoy, Blue Ace, Bolton, Icon, and Sunter, were evaluated before storage, after approximately six months of storage at 5 °C and 60% relative humidity, and following the transfer period. Seedling length, root length, vegetative fresh and dry weight, and root fresh and dry weight were assessed. Seed coating, storage, cultivar, and their interactions significantly affected seedling development traits. Coating increased mean seedling length from 5.92 to 6.17 cm, corresponding to an increase of approximately 4.22%. Mean seedling length increased from 5.25 cm before storage to 6.44 cm after storage and remained nearly stable at 6.43 cm after transfer. Icon showed the highest overall seedling length (6.29 cm), while the highest individual value, 7.36 cm, was recorded in coated Icon seeds after storage. In contrast, coating reduced mean root length from 5.44 to 5.23 cm, while storage decreased root length from 6.42 cm before storage to 4.61 cm after storage, followed by partial recovery to 4.96 cm after transfer. Coating increased vegetative dry weight by approximately 10% and root fresh weight by 53.19%, whereas root dry weight decreased by 45.45%. Overall, seed coating promoted shoot development and selected biomass components, whereas its effects on root development varied according to cultivar and storage stage. These findings indicate that coating and storage protocols should be optimized on a cultivar-specific basis to maintain balanced early seedling development in commercial alfalfa seed production.
Keywords: Biomass, Seed Coating, Seedling Development, Storage, Transportation.

INTRODUCTION
Alfalfa (*Medicago sativa* L.) is considered one of the most important forage crops worldwide because of its high forage quality, perennial growth habit, broad adaptability, and ecological and agronomic contributions to agricultural production systems through symbiotic nitrogen fixation (Rocha et al., 2019; Zhang et al., 2022). The establishment of a persistent and highly productive alfalfa stand depends not only on seed viability but also on the rapid development of vigorous and normal seedlings following germination. The early seedling stage represents one of the most sensitive phases of plant development to environmental conditions, and morphological and physiological differences occurring during this period may substantially influence subsequent stand establishment (Rajjou et al., 2012). Therefore, traits such as seedling length, root length, the capacity to produce normal seedlings, and root and shoot fresh and dry weights are important indicators for evaluating seed vigor and early plant performance (Afzal et al., 2020; Rajjou et al., 2012).
Early seedling development results from coordinated physiological processes involving seed reserve mobilization and the formation of root and shoot tissues. After the seed takes up water, metabolic activity resumes, protein synthesis begins, cellular repair mechanisms activate, and stored reserves mobilize toward the embryonic axis, providing the physiological basis for seedling development (Rajjou et al., 2012). Rapid root development improves access to water and nutrients, whereas shoot development promotes the formation of photosynthetically active tissues and the transition from heterotrophic development to autotrophic growth. In contrast, physiological deterioration from seed aging or

environmental stresses may impair efficient utilization of stored reserves, resulting in reduced root and shoot elongation, lower biomass accumulation, and increased abnormal seedling formation. Therefore, integrating early seedling traits provides a more comprehensive assessment of a seed lot's physiological status than evaluating a single trait alone.

Seed-coating technologies have become an important component of modern seed technology because they can enhance early seedling development and crop establishment. Beyond forming a physical layer on the seed surface, coating materials can facilitate the controlled delivery of nutrients, biostimulants, plant protection products, and beneficial microorganisms in the immediate vicinity of the developing seedling (Afzal et al., 2020; Paravar et al., 2023). Appropriate coating formulations may positively influence root and shoot development by modifying the seed microenvironment and facilitating water and nutrient use during early growth. Studies conducted in alfalfa have demonstrated that different seed treatments can promote root development, seedling growth, and biomass accumulation, particularly under stress conditions; however, the magnitude and direction of these responses may vary depending on application rate, coating composition, genotype, and environmental conditions (Bıçakcı et al., 2018; Arslan et al., 2020; Öten and Tuzlacı, 2024). Conversely, inappropriate physical or chemical properties of the coating layer may alter water and gas exchange between the seed and its environment, thereby constraining early seedling development. Consequently, evaluate the effects of coating treatments on seedling performance in relation to both cultivar and application conditions (Qiu et al., 2020; Sprey et al., 2025).

Evaluation of the seedling establishment capacity of coated seeds solely on the basis of their initial performance immediately after coating may not adequately represent the actual conditions encountered by commercial seed lots. After coating, seeds are typically stored for varying periods and then transported before reaching the sowing site. Physiological aging during storage, influenced by temperature, relative humidity, and particularly seed moisture content, may reduce seed vigor by deteriorating membrane integrity, protein structure, DNA integrity, and cellular repair mechanisms (Rajjou and Debeaujon, 2008; Rajjou et al., 2012). The consequences of vigor loss may become apparent before complete loss of viability through reduced root and shoot growth, decreased capacity to produce normal seedlings, and lower seedling biomass. In addition, the moisture balance, mechanical integrity, and storage stability of coating materials may modify the response of coated seeds to storage, while environmental and physical stresses encountered during transportation may impose additional stress on seeds already affected by storage-related physiological changes (Afzal et al., 2020; Paravar et al., 2023; Sprey et al., 2025). These considerations highlight the need to evaluate coating × storage × transportation interactions in relation to early seedling development.

This study aimed to determine changes in early seedling growth performance in coated and uncoated seeds of different alfalfa cultivars before storage, after storage, and after storage plus transportation. Specifically, the study aimed to determine the individual and interactive effects of cultivar, seed coating, and storage/transportation processes on seedling length, root length, vegetative fresh and dry weight, and root fresh and dry weight. Comparing seedling growth responses among alfalfa cultivars that differ in genetic background and dormancy characteristics with coating and storage conditions is particularly important for identifying physiological changes in seed vigor that may not be detectable through final viability measurements alone. Accordingly, the study aimed to determine whether coating effects on early seedling development were maintained throughout storage and transportation and to characterize cultivar-specific responses to these processes. The findings are expected to provide a scientific basis for optimizing the commercial storage and distribution of coated alfalfa seeds and maintaining high seedling establishment potential before sowing.

MATERIALS AND METHODS

Plant Material

This study was conducted during 2024–2025 in the laboratories of the Ankara Seed Registration and Certification Directorate to determine changes in seed viability and germination performance of uncoated and coated alfalfa (*Medicago sativa* L.) seeds before storage, after storage, and after storage plus transportation. Seeds of five alfalfa cultivars representing different dormancy groups—Bilensoy-80, Blue Ace, Bolton, Icon, and Sunter—were used as plant material. Seeds from the same seed lot of each cultivar were divided into two groups, coated and uncoated, to allow direct comparison of coating

treatments. Seed coating was performed by ABEL Tohumculuk A.Ş. at a 1:1 (w/w) ratio, corresponding to the application of 1 kg of coating material per 1 kg of seed.

The cultivars differed in dormancy level and agronomic characteristics. Bilensoy-80 (dormancy group 4) is characterized by its adaptation to the Central Anatolian and Transitional Regions and its tolerance to winter conditions, drought, and lodging. Blue Ace (dormancy group 9) is characterized by a semi-erect growth habit, fine stems, a high leaf-to-stem ratio, strong seedling vigor, and adaptation to hot and dry conditions. Bolton (dormancy group 5) is characterized by high fresh and dry forage yields and high crude protein content. Icon (dormancy group 6) is distinguished by high seedling vigor and a high leaf-to-stem ratio, together with resistance to lodging, Fusarium, and Phytophthora. Sunter (dormancy group 5–7) is characterized by a strong and deep root system, rapid regrowth capacity, high forage yield potential, and tolerance to adverse winter conditions. Thus, cultivars differing in genetic and agronomic characteristics and dormancy levels enabled comparative evaluation of their physiological responses to seed coating, storage, and transportation.

Methods

Seed Physiological Quality Before Storage

To determine seed physiological quality before storage, seeds obtained from harvested plants that had not yet been subjected to any storage or transportation process were used. Standard germination tests were conducted in accordance with the rules of the International Seed Testing Association (ISTA) to determine the initial physiological quality of the seeds. Seedling length, root length, and fresh and dry biomass accumulation were determined. These values served as baseline data for evaluating changes after storage and transportation (ISTA, 2025).

Seed Physiological Quality After Storage

To determine the effects of storage on seed physiological quality and early seedling development, seeds were stored for approximately six months at +5 °C and 60% relative humidity. After the storage period, the physiological quality characteristics of the seeds were reassessed in accordance with ISTA rules. Standard germination tests were conducted, and seedling length, root length, and fresh and dry biomass accumulation were determined. The results were compared with the pre-storage values to evaluate the effects of the six-month storage period on seed physiological quality and early seedling development (ISTA, 2025).

Seed Physiological Quality After Storage and Transportation

To determine the effects of post-storage transportation on seed performance, seeds stored for approximately six months at +5 °C and 60% relative humidity underwent a 16-h transportation period after storage. Following transportation, seed physiological quality and early seedling growth performance were evaluated in accordance with ISTA rules. Seedling length, root length, and fresh and dry biomass accumulation were determined. The resulting data were compared with those obtained before and after storage to evaluate the sequential effects of storage and subsequent transportation on seed physiological quality and early seedling development (ISTA, 2025).

Statistical Analysis

Data from the study were analyzed using analysis of variance (ANOVA) in JMP statistical software. When ANOVA detected significant effects or interactions, means were compared using Tukey's Honestly Significant Difference (HSD) multiple-comparison test in JMP (JMP, 2023). Statistical significance was evaluated at the 5% probability level ($p < 0.05$), and differences among means were indicated by letter groupings.

RESULTS AND DISCUSSION

Seedling Length

Analysis of variance revealed that seedling length in alfalfa was significantly affected by the main effects of coating, storage, and cultivar, as well as by all two-way and three-way interactions ($p < 0.01$) (Table 1). Overall, seed coating increased seedling length from 5.92 cm in uncoated seeds to 6.17 cm in coated seeds, an increase of approximately 4.22%. Across storage stages, mean seedling length increased from 5.25 cm before storage to 6.44 cm after storage and remained nearly unchanged at 6.43 cm after transportation, with the latter two stages in the same statistical group. The coating × storage

interaction showed that this response differed by coating status. In uncoated seeds, seedling length increased from 5.02 cm before storage to 6.49 cm after storage and subsequently decreased to 6.25 cm after transportation. In coated seeds, the corresponding values were 5.49, 6.39, and 6.62 cm, respectively. Thus, the advantage of coating was particularly evident after transportation, when coated seeds showed the greatest mean seedling length. However, the increase in seedling length observed after storage should not be interpreted as evidence of a direct growth-promoting effect of storage. Rather, consider this response in relation to the physiological status of seeds that successfully germinated after storage, reserve mobilization, and genotype-specific growth capacity (Table 2).

RESULTS AND DISCUSSION

Seedling Length

Analysis of variance revealed that seedling length in alfalfa was significantly affected by the main effects of coating, storage, and cultivar, as well as by all two-way and three-way interactions ($p < 0.01$) (Table 1). Overall, seed coating increased seedling length from 5.92 cm in uncoated seeds to 6.17 cm in coated seeds, an increase of approximately 4.22%. Across storage stages, mean seedling length increased from 5.25 cm before storage to 6.44 cm after storage and remained nearly unchanged at 6.43 cm after transportation, with the latter two stages in the same statistical group. The coating × storage interaction showed that this response differed by coating status. In uncoated seeds, seedling length increased from 5.02 cm before storage to 6.49 cm after storage and subsequently decreased to 6.25 cm after transportation. In coated seeds, the corresponding values were 5.49, 6.39, and 6.62 cm, respectively. Thus, the advantage associated with coating was particularly evident after transportation, when coated seeds exhibited the greatest mean seedling length. However, the increase in seedling length observed after storage should not be interpreted as evidence of a direct growth-promoting effect of storage. Rather, this response should be considered in relation to the physiological status of seeds that successfully germinated after storage, reserve mobilization, and genotype-specific growth capacity (Table 2).

Marked genotypic differences in seedling length were observed, with Icon exhibiting the greatest overall mean (6.29 cm), followed by Blue Ace (6.20 cm), Sunter (6.12 cm), Bolton (5.96 cm), and Bilensoy (5.65 cm). Although coating increased seedling length in all cultivars, the magnitude of the response varied among genotypes. Relative to uncoated seeds, seedling length increased by 6.58% in Bilensoy, 5.22% in Icon, 4.46% in Bolton, 3.32% in Sunter, and 1.46% in Blue Ace. The cultivar × storage interaction also showed that cultivars differed in growth responses across storage stages; Icon reached the greatest value after storage (7.00 cm), whereas Blue Ace showed the greatest value after transportation (6.79 cm). The three-way interaction showed substantial variation among treatment combinations, ranging from 4.67 to 7.36 cm. The greatest seedling length was recorded for coated Icon after storage (7.36 cm), followed by coated Blue Ace after transportation (7.06 cm) and uncoated Blue Ace after storage (7.00 cm), whereas the lowest value was observed for uncoated Bolton before storage (4.67 cm). This pronounced interaction demonstrates that, although coating generally promoted seedling elongation, the magnitude of its effect depended on cultivar and storage stage. In particular, the high performance of coated Icon after storage and coated Blue Ace after transportation indicates that seedling development cannot be explained solely by the main effect of coating and that cultivar × coating × storage/transportation compatibility should also be considered (Table 2).

[1]Means followed by the same letter are not significantly different.

The overall increase in seedling length associated with coating is consistent with previous reports indicating that appropriately designed coating systems may promote early seedling growth. Amirkhani et al. (2016, 2019) reported that plant-protein- and biostimulant-based coatings could improve early plant development, whereas Qiu et al. (2020) demonstrated that seedling responses may vary depending on coating formulation and plant species. Sprey et al. (2025) further emphasized that the physical and chemical properties of coating materials, particularly their water relations and storage stability, critically determine coating performance. The greater seedling length observed after storage in the present study may be related to physiological processes such as metabolic activation, maintenance of cellular integrity, and efficient mobilization of seed reserves during seedling growth, as emphasized by Rajjou et al. (2012). Nevertheless, the coating-induced increase was limited to 1.46% in Blue Ace but reached 6.58% in Bilensoy, indicating a strong genotypic component in the early seedling growth response. This interpretation is also consistent with Öten and Tuzlacı (2024), who reported that different priming and coating treatments could substantially modify early seedling development in alfalfa, and with Jabri et al. (2021) and Zhou et al. (2024), who demonstrated differential physiological responses of alfalfa genotypes to environmental conditions. Overall, coating increased seedling length, but cultivar and storage/transportation stage significantly modulated the magnitude of this effect. Therefore, coating technologies intended to improve early seedling development in alfalfa should be optimized according to cultivar and storage conditions rather than applied as a uniform, genotype-independent treatment.

The overall reduction in root length associated with coating indicates that seed-coating treatments do not invariably benefit early seedling development and that coating material, formulation, genotype, and environmental conditions should be considered jointly. Qiu et al. (2020) reported that the effects of seed coating on seedling development may vary depending on coating formulation and plant species, whereas Amirkhani et al. (2016, 2019) demonstrated that appropriately formulated biostimulant- and protein-based coatings could promote seedling development. These contrasting findings indicate that the biological effects of coatings are strongly modulated by coating material characteristics and application conditions. The coating thickness, physical integrity, water and gas exchange properties, and storage stability emphasized by Afzal et al. (2020) and Sprey et al. (2025) may also help explain the greater reduction in root length observed in coated seeds after storage in the present study. Furthermore, the decrease in root length from 6.42 cm before storage to 4.61 cm after storage indicates that root development was sensitive to storage-related physiological changes and is broadly consistent with the findings of Jungers et al. (2016) and Zhou et al. (2024), who reported that environmental conditions can substantially influence germination and early seedling development in alfalfa. The differential responses of root and early seedling traits to priming and coating treatments in alfalfa reported by Öten and Tuzlacı (2024) further support the cultivar × coating responses observed in the present study. Overall, greater initial root length did not necessarily confer greater tolerance to storage, nor did coating alone ensure superior root development. Instead, root growth maintenance appeared to depend on compatibility among genotype, coating material, and storage conditions. Therefore, when optimizing coating technologies for alfalfa, maintaining root development after storage should be considered an important vigor criterion alongside germination performance.

Vegetative Fresh Weight

Analysis of variance revealed that vegetative fresh weight in alfalfa was significantly affected by the main effects of coating, storage, and cultivar, as well as by all two-way and three-way interactions ($p < 0.01$) (Table 1). Across the overall means, seed coating reduced vegetative fresh weight from 0.208 g in uncoated seeds to 0.205 g in coated seeds, corresponding to a slight decrease of approximately 1.44%. In contrast, the effect of storage stage was considerably more pronounced. Vegetative fresh weight decreased from 0.187 g before storage to 0.181 g after storage and subsequently increased to 0.251 g

after transportation, representing an increase of approximately 34.22% relative to the pre-storage value. The coating × storage interaction also showed that this response differed by coating status. In uncoated seeds, vegetative fresh weight was 0.179, 0.190, and 0.255 g before storage, after storage, and after transportation, respectively, whereas in coated seeds it was 0.195, 0.172, and 0.248 g. Thus, coating was associated with greater fresh biomass before storage but with lower values after storage and transportation. Nevertheless, because both coated and uncoated seeds exhibited their greatest biomass after transportation, the variation in vegetative fresh weight appears to have been shaped primarily by the interaction between coating status and storage/transportation stage rather than by the main effect of coating alone (Table 2).

Cultivars differed significantly in their capacity for biomass accumulation. Across the overall means, Icon and Sunter had the highest vegetative fresh weight (0.221 g), Blue Ace an intermediate value (0.209 g), and Bilensoy and Bolton lower values (0.191 g). The response to coating was also strongly genotype-dependent. Among the cultivar × coating combinations, coated Icon exhibited the greatest value (0.232 g), whereas vegetative fresh weight in Blue Ace decreased from 0.226 g in uncoated seeds to 0.192 g following coating. The cultivar × storage interaction further showed that Blue Ace (0.274 g), Sunter (0.273 g), and Icon (0.264 g) exhibited pronounced biomass accumulation after transportation. The three-way interaction revealed even greater differentiation, with values ranging from 0.126 to 0.285 g. The greatest vegetative fresh weight was recorded for coated Icon after transportation (0.285 g), whereas the lowest value was observed for coated Blue Ace after storage (0.126 g). In particular, the increase in coated Blue Ace from 0.126 g after storage to 0.271 g after transportation, together with the maximum value of 0.285 g for coated Icon after transportation, shows that fresh biomass response to storage and transportation was nonlinear and strongly dependent on the cultivar × coating combination. Therefore, the relatively small overall effect of coating on vegetative fresh weight may mask pronounced positive or negative responses within specific cultivar and storage-stage combinations, indicating that treatment efficacy should not be evaluated solely on the basis of main-effect means (Table 2).

The relatively limited overall change in vegetative fresh weight associated with coating suggests that seed-coating technologies may not have a unidirectional effect on early seedling biomass and may vary by coating material, genotype, and environmental conditions. Amirkhani et al. (2016, 2019) reported that protein- and biostimulant-based coating systems can promote seedling development when appropriately formulated, whereas Qiu et al. (2020) showed that coating efficacy varies by formulation and plant species. Similarly, Afzal et al. (2020) emphasized that coating technologies can facilitate the targeted delivery of active ingredients to the seed microenvironment, but that coating material and application rate are critical for successful seedling establishment. Findings reported for alfalfa by Öten and Tuzlacı (2024) and Arslan et al. (2020) further support interpreting early growth responses to coating in conjunction with application and environmental conditions. In the present study, the relatively high biomass accumulation of Icon and Sunter, together with the contrasting coating responses observed in Icon and Blue Ace, indicates that genotypic variation was an important determinant of coating efficacy. This interpretation is consistent with Xie et al. (2023) and Zhou et al. (2024), who reported differential physiological responses among alfalfa genotypes during early seedling development. Sprey et al. (2025) also emphasized the importance of the physical and chemical properties of coating materials in understanding these genotype-specific responses. Overall, although the main effect of coating was limited to a 1.44% reduction in vegetative fresh weight, the marked difference between coated Icon after transportation (0.285 g) and coated Blue Ace after storage (0.126 g) demonstrates that early biomass accumulation was largely determined by cultivar × coating × storage/transportation compatibility. Therefore, coating technologies intended to improve biomass accumulation in alfalfa should be optimized by genotype and storage conditions rather than applied with a uniform treatment strategy.

Vegetative Dry Weight

Analysis of variance revealed that vegetative dry weight in alfalfa was significantly affected by the main effects of coating, storage, and cultivar, as well as by all two-way and three-way interactions ($p < 0.01$) (Table 1). Across the overall means, seed coating increased vegetative dry weight from 0.010 g in uncoated seeds to 0.011 g in coated seeds, corresponding to an increase of approximately 10%. A similar increasing trend was observed across storage stages, with dry weight increasing from 0.009 g before storage to 0.011 g after storage and 0.012 g after transportation. Thus, relative to the pre-storage value, dry matter accumulation increased by approximately 22.22% after storage and 33.33% after

transportation. However, the significant coating × storage interaction indicates that these changes cannot be explained by the independent effects of coating or storage alone. In contrast to the relatively limited effect of coating on fresh biomass, the increase in dry matter accumulation associated with coating suggests that coating may influence dry matter deposition and biomass allocation within seedling tissues differently from its effect on overall seedling size. Nevertheless, the greater dry weight values observed after storage and transportation should not be interpreted as evidence of a direct stimulatory effect of these processes. Rather, they should be considered in relation to the physiological performance of seedlings that successfully developed and the mobilization of seed reserves into seedling tissues (Table 3).

Cultivars differed significantly in their capacity for vegetative dry matter accumulation. Across the overall means, Sunter had the highest vegetative dry weight (0.012 g), followed by Blue Ace and Bolton (0.011 g), whereas Bilensoy and Icon had values of 0.010 g. Responses to coating were also genotype-dependent. Coating increased vegetative dry weight from 0.010 to 0.011 g in Bolton and from 0.009 to 0.011 g in Icon, whereas a slight reduction from 0.012 to 0.011 g was observed in Sunter; changes in Bilensoy and Blue Ace were comparatively limited. The cultivar × storage interaction showed that Blue Ace and Sunter reached 0.013 and 0.014 g, respectively, after transportation and were included in the highest statistical group, demonstrating that genotypes differed in their dry matter accumulation responses to storage and transportation. This variation became even more evident in the three-way interaction, with values ranging from 0.007 to 0.014 g across treatment combinations. The greatest vegetative dry weight was recorded for coated Blue Ace after transportation (0.014 g), while uncoated Blue Ace after storage and uncoated Sunter after transportation also exhibited high values of 0.014 g. The lowest value was observed for coated Bilensoy before storage (0.007 g). In particular, the increase in coated Blue Ace from 0.008 g before storage to 0.014 g after transportation and in coated Icon from 0.008 to 0.012 g demonstrates that the effect of coating varied substantially among genotypes depending on storage stage. Therefore, considering specific cultivar × coating × storage combinations, rather than relying on the overall coating mean alone, provides a more biologically meaningful interpretation of dry biomass accumulation (Table 3).

The increase in vegetative dry weight associated with coating is broadly consistent with previous studies indicating that appropriately designed seed-coating systems may promote early seedling development and biomass accumulation. Amirkhani et al. (2016) demonstrated the potential of biologically derived coating components to promote seedling and plant development, while Afzal et al. (2020) emphasized that modern coating technologies may improve seedling establishment by facilitating the targeted delivery of active ingredients to the seed microenvironment. In alfalfa, Öten and Tuzlacı (2024) similarly reported that different priming and coating treatments could modify germination and early seedling development, with seedling biomass traits varying substantially among treatments. Arslan et al. (2020) also demonstrated that coated alfalfa seeds may respond differently to environmental conditions, indicating that coating performance should not be evaluated independently of application conditions. In the present study, although coating increased overall vegetative dry weight by approximately 10%, the response was positive in Bolton and Icon but slightly negative in Sunter, indicating a strong genotypic component in the biomass response to coating. Furthermore, the increase in overall dry weight from 0.009 g before storage to 0.012 g after transportation, along with the highest value observed for the coated Blue Ace × after-transportation combination, demonstrates the dynamic nature of early seedling biomass responses to coating and storage/transportation. Overall, high and stable dry matter accumulation in alfalfa cannot be attributed solely to coated seeds; rather, the biological effectiveness of coating is substantially modulated by genotype and storage/transportation stage. Therefore, cultivar × coating × storage compatibility should be a key optimization criterion when using coating technologies to improve early seedling biomass accumulation in alfalfa.

Table 3. Mean vegetative dry weight (g), root fresh weight (g), and root dry weight (g) of alfalfa cultivars under different coating treatments and storage stages, with statistical groupings

[1]Means followed by the same letter are not significantly different.

Root Fresh Weight

Analysis of variance revealed that root fresh weight in alfalfa was significantly affected by the main effects of coating, storage, and cultivar, while the cultivar × coating, cultivar × storage, and cultivar × coating × storage interactions were also statistically significant. In contrast, the nonsignificant coating × storage interaction indicates that the relationship between the average effects of coating and storage was relatively limited when cultivar was not considered (Table 1). Across the overall means, seed coating increased root fresh weight from 0.047 g in uncoated seeds to 0.072 g in coated seeds, an increase of approximately 53.19%, indicating strong potential for coating to promote root biomass accumulation. However, storage had a much stronger effect. Root fresh weight decreased from 0.106 g before storage to 0.010 g after storage, representing a reduction of approximately 90.57%. After transportation, it increased to 0.063 g, indicating substantial recovery, although it remained approximately 40.57% below the pre-storage level. This pronounced variation demonstrates that root fresh biomass was highly sensitive to storage stage. Therefore, despite the overall positive effect of coating, storage-related physiological changes appeared to exert a much stronger influence on root biomass, and the recovery

observed after transportation was insufficient to fully restore the initial level of root development (Table 3).

Genotypic differences were a major determinant of variation in root fresh weight. Across the overall means, Sunter exhibited the greatest root fresh weight (0.099 g), followed by Bilensoy (0.062 g), whereas Icon (0.047 g), Blue Ace (0.046 g), and Bolton (0.043 g) showed lower and statistically similar values. However, responses to coating differed markedly among cultivars. Coating increased root fresh weight in Sunter from 0.051 to 0.148 g, corresponding to an increase of approximately 190.20%, and in Bilensoy from 0.039 to 0.085 g, representing an increase of 117.95%. In contrast, root fresh weight decreased by approximately 16.00%, 6.67%, and 19.23% in Blue Ace, Bolton, and Icon, respectively. The cultivar × storage interaction showed a similarly pronounced genotypic differentiation. Root fresh weight decreased sharply after storage in all cultivars, whereas after transportation, Sunter increased to 0.177 g and clearly differentiated from the other cultivars. This variation became even more evident in the three-way interaction, with treatment combinations ranging from 0.003 to 0.303 g. The greatest root fresh weight was recorded for coated Sunter after transportation (0.303 g), whereas the lowest value was observed for coated Blue Ace after storage (0.003 g). These findings demonstrate that the large overall increase in root biomass associated with coating should not be interpreted as a common response across all genotypes; rather, the overall mean was strongly influenced by the pronounced positive responses of Sunter and Bilensoy. Therefore, evaluating the agronomic effectiveness of coating requires considering specific cultivar × coating × storage combinations rather than relying solely on overall treatment means (Table 3).

The overall increase in root fresh weight associated with coating is consistent with previous studies indicating that appropriately designed coating systems may promote early root development and seedling biomass accumulation. Amirkhani et al. (2016, 2019) reported that coatings containing protein-based and biologically derived biostimulant components could promote seedling development, while Afzal et al. (2020) emphasized the potential of modern coating technologies to improve seedling establishment by delivering active ingredients to the seed microenvironment. Similarly, Qiu et al. (2020) demonstrated that biostimulant-containing coatings may promote germination and early seedling development in forage legumes, although coating performance depends on the formulation and plant material. This genotype dependence was particularly pronounced in the present study: coating markedly increased root fresh biomass in Sunter and Bilensoy but did not provide the same advantage in Blue Ace, Bolton, or Icon. Furthermore, the more than 90% reduction in overall root fresh weight after storage indicates that the potential benefits of coating cannot be considered independently of storage-related physiological changes and suggests that root biomass may be a sensitive indicator of changes in seed physiological quality. Within the three-way interaction, coated Sunter reached 0.303 g after transportation, by far the greatest value among the treatment combinations, demonstrating that an appropriate cultivar × coating combination may generate a particularly strong root growth response under specific conditions. Therefore, rather than adopting a uniform “coated seed” approach to improve root development in alfalfa, consider genotype-specific responses and post-storage performance jointly. In cultivars such as Sunter and Bilensoy, which exhibited particularly strong positive responses to coating, targeted optimization of coating materials and application conditions may provide a more appropriate strategy.

Root Dry Weight

Analysis of variance revealed that root dry weight in alfalfa was significantly affected by the main effects of coating, storage, and cultivar, as well as by all two-way and three-way interactions ($p < 0.01$) (Table 1). Across the overall means, root dry weight decreased from 0.011 g in uncoated seeds to 0.006 g in coated seeds, corresponding to a reduction of approximately 45.45% associated with coating. Storage had an even more pronounced effect. Root dry weight decreased from 0.018 g before storage to 0.003 g after storage, a reduction of 83.33%; although it subsequently increased to 0.005 g after transportation, it remained 72.22% below the pre-storage value. The coating × storage interaction showed that the magnitude of this reduction differed by coating status. In uncoated seeds, root dry weight decreased from 0.027 g before storage to 0.003 g after storage and 0.004 g after transportation, whereas the corresponding values for coated seeds were 0.008, 0.003, and 0.006 g, respectively. Notably, although coating reduced root dry weight across the overall means, coated seeds exhibited 50% greater root dry weight than uncoated seeds after transportation. This finding suggests that, although coating

may restrict root dry matter accumulation under initial conditions, it may reduce biomass loss or facilitate recovery during storage and transportation. Nevertheless, because the interaction effects were significant, interpret this response in the context of cultivar-specific treatment combinations rather than as a uniform protective effect of coating (Table 3).

Marked differences in root dry weight were observed among cultivars. Across the overall means, Bolton exhibited the greatest value (0.021 g) and was clearly differentiated from the other cultivars, followed by Sunter (0.007 g), Bilensoy (0.006 g), Icon (0.005 g), and Blue Ace (0.004 g). However, Bolton's superior overall mean should be interpreted cautiously because it was largely driven by the exceptionally high value of 0.105 g recorded for uncoated seeds before storage, and this performance was not maintained after storage. Indeed, within the cultivar × storage interaction, root dry weight in Bolton decreased from 0.055 g before storage to 0.002 g after storage and recovered only slightly to 0.005 g after transportation. Responses to coating were also genotype-dependent: coating increased dry matter accumulation in Bilensoy and especially in Icon, whereas Bolton and Sunter showed reductions. The three-way interaction clearly drove this variation, with treatment combinations ranging from 0.001 to 0.105 g. Uncoated Bolton had the highest root dry weight before storage (0.105 g), whereas uncoated Icon and coated Blue Ace had the lowest values after storage (0.001 g). In contrast, root dry weight in coated Bolton increased from 0.005 g before storage to 0.008 g after transportation, suggesting that coating may produce a different compensatory or potentially protective response in certain genotypes following storage and transportation. Thus, high initial root dry weight did not necessarily correspond to greater storage tolerance, and coating efficacy should be evaluated based on cultivar × coating × storage combinations rather than overall treatment means alone (Table 3).

The overall reduction in root dry weight associated with coating indicates that seed-coating technologies may affect different morphological and biomass components of the root system in different directions. Bıçakcı et al. (2018) reported that coating treatments in alfalfa could increase germination and radicle fresh weight under stress conditions while producing different responses in traits such as radicle length and dry weight. Similarly, Arslan et al. (2020) showed that environmental stress substantially affected root and shoot length, as well as fresh and dry biomass traits, in coated alfalfa seeds, indicating that coating efficacy depends on the environmental conditions under which seeds develop. Öten and Tuzlacı (2024) likewise reported treatment-dependent differences in early seedling traits, including root fresh and dry weight, following different priming and coating treatments in alfalfa. In this context, the decrease in root dry weight from 0.018 g before storage to 0.003 g after storage in the present study shows that storage was a major factor limiting root dry matter accumulation, beyond the main effect of coating. More importantly, although coating was associated with an overall reduction of 45.45%, coated seeds exhibited greater root dry weight than uncoated seeds after transportation, demonstrating that the direction and magnitude of the coating response varied across storage stages. Overall, maintaining root dry matter accumulation in alfalfa is too complex to attribute solely to coated seeds and requires consideration of the cultivar × coating × storage/transportation interaction. Therefore, post-storage biomass retention and genotype-specific responses, rather than initial performance alone, should be considered key selection criteria when optimizing seed-coating technologies for alfalfa.

CONCLUSION

This study showed that the effects of seed coating, storage, and transportation on early seedling development and biomass accumulation in alfalfa varied substantially by trait and cultivar. Seed coating increased seedling length and vegetative dry weight, indicating positive effects on shoot development and dry matter accumulation, whereas it reduced root length and root dry weight; in contrast, root fresh weight increased markedly following coating. Storage and transportation resulted in particularly pronounced changes in root-related traits, with substantial reductions in root length and root fresh and dry weight after storage, followed by partial recovery in some traits and cultivars after transportation. Conversely, the increases observed in seedling length and vegetative dry weight after storage and/or transportation indicate that coating and storage processes elicited contrasting responses among different components of seedling development. The significant cultivar × coating, cultivar × storage, and particularly three-way interactions clearly demonstrate that a uniform coating strategy is unlikely to produce equivalent responses across all alfalfa cultivars. Indeed, Icon was distinguished by greater seedling length, Sunter by root length and root fresh biomass, and Bolton by high initial root dry matter accumulation; however, the extent to which these advantages were maintained varied according to

coating and storage conditions, demonstrating that high initial performance does not necessarily confer greater storage tolerance. Overall, the effectiveness of coating technologies in commercial alfalfa seed production should be evaluated not only according to their initial effects but also according to the extent to which seedling vigor and the balance between root and shoot development are maintained throughout storage and transportation. Therefore, genotype-specific optimization of coating materials and storage protocols is an important strategy for maintaining high, balanced post-storage seedling performance and improving the commercial effectiveness of coated alfalfa seeds.

ACKNOWLEDGMENTS

Özet
Kuraklık stresi, tarla bitkilerinde tohum çimlenmesini ve erken fide gelişimini sınırlandıran başlıca abiyotik stres faktörlerinden biridir. Kurak ve yarı kurak tarım ekosistemlerinde yetersiz toprak nemi; tohumların su alımını kısıtlamakta, enzimatik aktivasyonu aksatmakta, rezerv maddelerin mobilizasyonunu geciktirmekte ve oksidatif stresi artırarak düşük çıkış oranı ile düzensiz bitki kuruluşuna yol açmaktadır. Tohum primingi, tohumların kontrollü koşullarda kısmi hidrasyona tabi tutulması ve radikula çıkışı gerçekleşmeden yeniden kurutulması esasına dayanan bir ekim öncesi uygulamadır. Biyostimülantlarla desteklenen tohum primingi ise kuraklık toleransının artırılmasında sürdürülebilir ve yenilikçi bir yaklaşım olarak öne çıkmaktadır. Bu derleme çalışmasında, biyostimülant destekli tohum priminginin tarla bitkilerinde çimlenme özellikleri, fide canlılığı ve fizyolojik tolerans mekanizmaları üzerindeki etkilerine ilişkin güncel bilimsel bulgular değerlendirilmiştir. İncelenen biyostimülantlar arasında deniz yosunu ekstraktları, humik ve fulvik asitler, amino asitler, protein hidrolizatları, kitosan, bitki gelişimini teşvik eden rizobakteriler ve mikorizal mantarlar yer almaktadır. Literatür bulguları, biyostimülant destekli priming uygulamalarının su kısıtı altında çimlenme yüzdesini ve çıkış hızını; radikula ve koleoptil uzunluğunu, kök gelişimini ve erken dönem fide biyokütlesini iyileştirebildiğini göstermektedir. Biyostimülant destekli primingin kuraklık toleransına katkısı; bağıl su içeriğinin korunması, prolin ve çözünebilir şekerler gibi ozmotik düzenleyicilerin birikiminin desteklenmesi, antioksidan enzim aktivitelerinin artırılması, reaktif oksijen türlerinin neden olduğu hasarın sınırlandırılması, hücre zarı bütünlüğünün korunması ve besin elementi alım etkinliğinin iyileştirilmesiyle ilişkilendirilmektedir. Bununla birlikte, uygulamaların etkinliği; bitki türü ve çeşidi, biyostimülantın bileşimi, dozu ve uygulama süresi, tohumun fizyolojik kalitesi, stres şiddeti ve çevresel koşullara bağlı olarak değişmektedir. Sonuç olarak biyostimülant destekli tohum primingi, iklim değişikliği koşullarında erken gelişme dönemindeki kuraklık kaynaklı kayıpları azaltmaya katkı sağlayabilecek, çevre dostu ve ekonomik bir yönetim stratejisi olarak değerlendirilebilir.
Anahtar kelimeler: Tohum primingi, biyostimülant, kuraklık stresi, çimlenme, fide gelişimi, tarla bitkileri.

Abstract
Drought stress is one of the major abiotic stress factors limiting seed germination and early seedling development in field crops. In arid and semi-arid agroecosystems, insufficient soil moisture restricts water uptake by seeds, disrupts enzymatic activity, delays the mobilization of storage reserves, and increases oxidative stress, leading to low emergence rates and uneven crop establishment. Seed priming is a pre-sowing treatment based on the partial hydration of seeds under controlled conditions, followed by redrying before radicle emergence. Biostimulant-assisted seed priming has emerged as a sustainable and innovative approach to improving drought tolerance. This review evaluates recent scientific findings on the effects of biostimulant-assisted seed priming on germination characteristics, seedling vigour, and physiological tolerance mechanisms in field crops. The biostimulants considered include seaweed extracts, humic and fulvic acids, amino acids, protein hydrolysates, chitosan, plant growth-promoting rhizobacteria, and mycorrhizal fungi. The literature indicates that biostimulant-assisted priming can improve germination percentage and emergence rate, as well as radicle and coleoptile length, root development, and early seedling biomass under water-limited conditions. The contribution of biostimulant-assisted priming to drought tolerance is associated with the maintenance of relative water

content, enhanced accumulation of osmolytes such as proline and soluble sugars, increased antioxidant enzyme activities, limitation of damage caused by reactive oxygen species, preservation of cell membrane integrity, and improved nutrient uptake efficiency. However, the effectiveness of these treatments varies depending on crop species and cultivar, biostimulant composition, application dose and duration, seed physiological quality, stress severity, and environmental conditions. In conclusion, biostimulant-assisted seed priming can be considered an environmentally friendly and cost-effective management strategy that may contribute to reducing drought-related losses during early crop development under changing climate conditions.
Keywords: Seed priming, biostimulants, drought stress, germination, seedling development, field crops.

GİRİŞ

İklim değişikliği, küresel tarımsal üretimin sürdürülebilirliğini tehdit eden başlıca çevresel sorunlardan biri hâline gelmiştir. Artan sıcaklıklar, yağış rejimlerindeki düzensizlikler ve ekstrem iklim olaylarının daha sık görülmesi, bitkisel üretimde verim düzeylerini olumsuz yönde etkileyerek önemli verim kayıplarına yol açmaktadır. IPCC raporlarında, küresel sıcaklık artışının özellikle kurak ve yarı kurak bölgelerde tarımsal üretim sistemleri üzerindeki baskıyı artıracağı, su kaynakları üzerindeki rekabeti güçlendireceği ve gıda güvenliği açısından önemli riskler oluşturacağı vurgulanmaktadır (IPCC, 2022). Bu bağlamda kuraklık, tarla bitkilerinin çimlenmeden hasada kadar tüm gelişim dönemlerini etkileyen ve verim kayıplarına neden olan en önemli abiyotik stres faktörlerinden biri olarak değerlendirilmektedir (Farooq et al., 2009; Marthandan et al., 2020).

Kurak ve yarı kurak alanların dünya tarım alanları içerisindeki yüksek payı, yağışa dayalı üretim yapan bölgelerin iklim değişikliğine karşı kırılganlığını artırmaktadır. Yağışların miktar, zaman ve dağılım bakımından düzensizleşmesi; toprak neminin kritik seviyelerin altına düşmesine, bitkilerin suya erişiminin sınırlanmasına ve özellikle erken gelişme döneminde düzensiz ve yetersiz bitki çıkışına neden olmaktadır (Singh et al., 2025; Janah et al., 2025). Türkiye'de Orta Anadolu, Güneydoğu Anadolu ve İç Ege başta olmak üzere birçok üretim bölgesinde kuraklık riski giderek daha belirgin hâle gelmektedir. Yağışlardaki azalma, yüksek sıcaklıklar ve yeraltı su kaynakları üzerindeki baskı; buğday, arpa, mısır, nohut ve yem bitkileri gibi stratejik öneme sahip tarla bitkilerinde üretim miktarını olumsuz etkilemekte ve verim düzeylerinin korunmasını güçleştirmektedir. Bu nedenle, kimyasal girdi kullanımını artırmadan bitkilerin stres toleransını destekleyebilecek çevre dostu ve uygulanabilir üretim yaklaşımlarına ihtiyaç duyulmaktadır (Yavaş et al., 2016; Ceritoğlu et al., 2021).

Bitki yaşam döngüsünde çimlenme ve erken fide gelişimi, kuraklık stresine karşı en hassas dönemler arasında yer almaktadır. Tohumun çimlenebilmesi için imbibisyonun gerçekleşmesi, enzimatik faaliyetlerin başlaması, depo maddelerinin mobilize edilmesi ve radikulanın tohum kabuğunu aşarak çıkış yapması gerekmektedir. Ancak toprak su potansiyelinin düşmesi, tohumun su alımını yavaşlatmakta, metabolik faaliyetleri sınırlandırmakta ve çimlenme oranı ile hızını azaltmaktadır (Bradford, 1986; Paparella et al., 2015).

Kuraklık koşullarında geç, düzensiz veya yetersiz bitki çıkışı; bitki sıklığının azalmasına, fide gelişiminin zayıflamasına ve sonuç olarak nihai verimin düşmesine neden olmaktadır. Buğday, mısır ve baklagil türlerinde kuraklık stresinin çimlenme, kök ve gövde gelişimi ile verim bileşenleri üzerinde önemli kayıplara yol açabildiği bildirilmektedir (Naseem ve Bano, 2014; Çığ et al., 2022). Erken dönemde ortaya çıkan düzensiz bitki çıkışı, yalnızca doğrudan verim kaybına neden olmamakta; aynı zamanda yeniden ekim gereksinimi, yabancı ot rekabetinin artması, sulama ve gübreleme uygulamalarının etkinliğinin azalması ve hasat homojenliğinin bozulması gibi ekonomik sonuçlar da doğurmaktadır. Bu nedenle, kuraklık koşullarında güçlü, düzenli ve yeterli bitki çıkışının sağlanması, üretim sistemlerinin dayanıklılığı açısından kritik önem taşımaktadır (Jatana et al., 2024). Yüksek fizyolojik kaliteye ve fide gücüne sahip tohumlar, uygun olmayan nem ve sıcaklık koşullarında daha hızlı çimlenebilmekte, daha düzenli çıkış gösterebilmekte ve erken gelişme döneminde çevresel streslere daha yüksek uyum sağlayabilmektedir (Heydecker et al., 1973; Bradford, 1986).

Bu olumsuzlukların azaltılmasında tohum primingi; tohumların ekim öncesinde kontrollü olarak nemlendirilmesi ve radikula çıkışı gerçekleşmeden yeniden kurutulması esasına dayanan, çimlenme ile erken fide gelişimini destekleyen düşük maliyetli ve çevre dostu bir ön ekim tekniği olarak öne çıkmaktadır (Bradford, 1986; Paparella et al., 2015). Tohum primingi uygulamalarının bitki gelişimini teşvik eden rizobakteriler (PGPR), fitohormonlar, ozmotik ajanlar ve doğal ekstraktlar gibi biyostimülantlarla desteklenmesi ise tohumların kuraklık stresine karşı toleransını artırma ve erken

dönem gelişimini güçlendirme açısından umut verici bir yaklaşım sunmaktadır (Mahakham et al., 2017; Marthandan et al., 2020).

Biyostimülant destekli tohum primingi uygulamalarının başarısı; bitki türü ve çeşidi, kullanılan biyostimülantın niteliği ve konsantrasyonu, priming süresi, uygulama yöntemi, kurutma koşulları ve stresin şiddeti gibi çeşitli faktörlere bağlı olarak değişebilmektedir. Bu nedenle, farklı tarla bitkilerinde elde edilen bulguların birlikte değerlendirilmesi ve uygulamaların etkinliğini belirleyen koşulların ortaya konulması önem taşımaktadır. Bu derlemenin amacı, kuraklık stresi altında biyostimülant destekli tohum primingi uygulamalarının tarla bitkilerinde çimlenme, erken fide gelişimi ve fizyolojik stres toleransı üzerindeki etkilerini güncel literatür ışığında değerlendirmektir. Bu kapsamda, başlıca tohum primingi yöntemleri ve biyostimülant grupları, uygulamaların olası etki mekanizmaları, farklı tarla bitkilerinde bildirilen sonuçlar, uygulama koşulları ve gelecekteki araştırma gereksinimleri ele alınacaktır.

MATERYAL VE YÖNTEM

Bu çalışma, tarla bitkilerinde kuraklık stresine karşı biyostimülant destekli tohum primingi uygulamalarının etkilerini, mekanizmalarını ve tarımsal çıktılarını inceleyen kapsamlı bir derleme araştırması niteliğindedir. Çalışmanın materyalini; Web of Science, Scopus, ScienceDirect, PubMed, Google Scholar ve TÜBİTAK ULAKBİM DergiPark gibi uluslararası ve ulusal akademik veri tabanlarında taranan, hakemli dergilerde yayımlanmış araştırma makaleleri, derlemeler ve resmi kurumsal raporlar oluşturmaktadır.

Literatür tarama sürecinde "seed priming", "biostimulants", "drought stress", "water deficit", "seed germination", "seedling establishment", "field crops", "PGPR", "mycorrhiza", "seaweed extract" ile bunların Türkçe karşılıkları olan "tohum primingi", "biyostimülant", "kuraklık stresi", "çimlenme", "fide gelişimi" ve "tarla bitkileri" anahtar kelimeleri kullanılmıştır. Taramada öncelikli olarak son yıllardaki güncel araştırmalar ile alandaki temel ve öncü metodolojik çalışmalara odaklanılmıştır.

Elde edilen veriler; kuraklık stresinin çimlenme ve fide fizyolojisine etkileri, tohum primingi teknikleri, biyostimülant grupları ve etki mekanizmaları, tarla bitkileri gruplarında (tahıllar, yemeklik dane baklagiller, yağ ve yem bitkileri) yürütülen somut uygulama örnekleri ile sahadaki kısıtlar ve araştırma gereksinimleri tematik başlıkları altında sentezlenmiş ve analitik bir yaklaşımla tartışılmıştır.

BULGULAR VE TARTIŞMA

Kuraklık Stresinin Çimlenme Ve Fide Gelişimine Etkileri

Kuraklık stresi, tarla bitkilerinde çimlenme ve erken fide gelişimi evrelerini doğrudan etkileyerek tohumun su alımını, enzimatik faaliyetlerini ve metabolik süreçlerini baskılayan başlıca çevresel sınırlayıcılardan biridir. Tohum çimlenmesi, fiziksel su alımıyla başlayan, metabolik hazırlıklarla devam eden ve kökçük çıkışıyla tamamlanan birbirini izleyen karmaşık biyolojik süreçlerden oluşmaktadır. Ortamda yeterli nem bulunmadığında tohumun su emilim hızı yavaşlamakta, embriyonik dokularda hücre bölünmesi ve büyümesi durmakta, dolayısıyla çimlenme süreci belirgin düzeyde gecikmektedir (Bradford, 1986; Paparella et al., 2015). Bu durum, kuraklık koşullarında tohumların çimlenme yüzdesi, çimlenme hızı ve tohum canlılık indekslerinde önemli gerilemelere neden olmakta; ortalama çimlenme süresini uzatarak tarladaki bitki çıkışını zayıflatmaktadır (Farooq et al., 2009; Kumari et al., 2026). Nitekim yapılan çalışmalarda, su kısıtının buğday, arpa, mısır, kolza ve sorgum gibi stratejik tarla bitkilerinde çimlenme performansını ve çıkış gücünü önemli ölçüde düşürdüğü bildirilmektedir (Li et al., 2020; Zhu et al., 2021; García-Cánovas et al., 2024).

Çimlenmeyi takip eden erken fide dönemi de su eksikliğine karşı oldukça hassastır. Toprak neminin yetersiz olması, genç fidelerde kök ve sürgün uzamasını sınırlandırmakta, taze ve kuru biyokütle birikimini büyük oranda azaltmaktadır. Dokuların yeterli su turgoruna ulaşamaması nedeniyle hücre genişlemesi durmakta, yaprak alanı küçülmekte, stomalar kapanmakta ve fotosentez kapasitesi zayıflayarak bitkinin erken dönemdeki büyüme ivmesi kaybolmaktadır (Begum et al., 2019; Jiménez-Arias et al., 2022). Bu süreçte kök sisteminin derinlere ve yanlara doğru yeterince gelişememesi, fidenin toprak profilindeki kısıtlı suya ve temel besin elementlerine erişim imkanını daha da daraltarak gelişme geriliğini derinleştirmektedir.

Fizyolojik gerilemelerin yanı sıra kuraklık stresi, hücresel düzeyde oksidatif dengenin bozulmasına da yol açmaktadır. Su açığı çeken bitki dokularında reaktif oksijen türlerinin kontrolsüz şekilde artması; hücresel membranların yapısını bozmakta, zar geçirgenliğini artırmakta ve doku hasarına zemin

hazırlamaktadır (Farooq et al., 2009; Marthandan et al., 2020). Nohut ve soya fasulyesi gibi baklagil türlerinde kuraklık, dokulardaki bağıl su içeriğini düşürerek hücre bütünlüğünde ciddi hasarlar oluşturmaktadır (Khan et al., 2019; Almakas et al., 2025). Her ne kadar bitkiler bu zararı sınırlandırmak amacıyla doğal koruyucu enzimlerini ve ozmotik dengeleyici maddeleri devreye sokmaya çalışsa da, kuraklığın şiddetli veya uzun süreli olması durumunda bu savunma kapasitesi yetersiz kalmaktadır. Sonuç olarak kuraklık stresi, tohum çimlenmesinden başlayarak erken fide büyümesini, bitki sıklığını ve genel tarla çıkışını doğrudan tehlikeye atan çok boyutlu bir olumsuzluk tablosu ortaya çıkarmaktadır (Jatana et al., 2024; Janah et al., 2025).

Tohum Primingi: Kavram, Amaç Ve Uygulama Yöntemleri

Tohum primingi, tohumların kontrollü koşullarda kısmi hidrasyona tabi tutulması, hücresel metabolik süreçlerin aktive edilmesi ve kökçük çıkışı gerçekleşmeden önce tohumların yeniden kurutulması esasına dayanan bir ön ekim tekniğidir (Bradford, 1986; Paparella et al., 2015). Bu uygulamanın temel amacı; çimlenme sürecinde rol oynayan enzim sistemlerini, hücresel onarım mekanizmalarını ve stres belleğini önceden harekete geçirerek tarlada daha hızlı, homojen ve çevresel streslere dirençli bir bitki çıkışı sağlamaktır. Düşük maliyetli, çevre dostu ve sahada uygulanabilir bir yaklaşım olması nedeniyle tohum primingi, kurak ve yarı kurak tarım alanlarında erken dönem risklerini azaltmada yaygın şekilde tercih edilmektedir (Ceritoğlu et al., 2021; Singh et al., 2025).

Uygulanan ajanın ve yöntemin niteliğine bağlı olarak priming teknikleri farklı gruplara ayrılmaktadır. Bunlardan en basiti olan hidropriming, tohumların saf su içerisinde belirli bir süre bekletilerek ardından kontrollü şekilde kurutulmasıdır; kimyasal kalıntı riski taşımaması ve pratik uygulanabilirliği sayesinde buğday, arpa, mısır ve baklagillerde tohum gücünü artırmada sıklıkla kullanılmaktadır (Marthandan et al., 2020). Osmopriming yönteminde ise polietilen glikol (PEG) gibi osmotik ajanlar kullanılarak su alımı sınırlandırılmakta, böylece kökçük çıkışı engellenirken tohumun metabolik hazırlığı tamamlanmaktadır (Paparella et al., 2015; Jatana et al., 2024). Halopriming uygulamalarında potasyum, kalsiyum veya sodyum tuz çözeltilerinden yararlanılarak tohumda hafif bir stres uyarımı oluşturulmakta ve bu sayede kuraklığa karşı çapraz tolerans geliştirilmektedir (Zhu et al., 2021).

Hormonal priming kapsamında giberellik asit, salisilik asit ve melatonin gibi düzenleyicilerin kullanımı; çimlenme enzimlerinin uyarılması, savunma mekanizmalarının güçlendirilmesi ve hücresel zar bütünlüğünün korunması yoluyla kuraklık kaynaklı kayıpları önemli ölçüde sınırlandırmaktadır (Kumari et al., 2026). Son yıllarda biyolojik yaklaşımların önem kazanmasıyla öne çıkan biyopriming tekniğinde ise tohumlar bitki gelişimini teşvik eden rizobakteriler (PGPR) veya mikorizal mantar türleriyle aşılanmaktadır (Harsonowati et al., 2026). Tohum yüzeyinde ve kök bölgesinde kolonize olan bu yararlı mikroorganizmalar, biyofilm matrisi oluşturarak su tutulmasını kolaylaştırmakta ve fidenin besin alımını desteklemektedir (Naseem ve Bano, 2014; Ansari et al., 2021). Benzer şekilde yeni nesil bir yaklaşım olan nanopriming uygulamaları da uygun dozlardaki nanopartiküller vasıtasıyla tohum içi metabolik süreçleri uyararak kuraklık direncini artırmayı hedeflemektedir (Jatana et al., 2024). Farklı mekanizmalar üzerinden işleyen bu yöntemler, kuraklık koşullarında tohumların fizyolojik performansını ve fide çıkış gücünü güvence altına almayı amaçlamaktadır.

Biyostimülant Kavramı ve Başlıca Biyostimülant Grupları

Biyostimülantlar, doğrudan bir besin maddesi sağlama amacı gütmeksizin, düşük dozlarda uygulandıklarında bitkilerin besin elementi kullanım etkinliğini artıran, abiyotik stres koşullarına tolerans kazandıran ve ürün kalitesini destekleyen doğal kökenli maddeler veya yararlı mikroorganizmalardır (Rouphael ve Colla, 2020). Avrupa Birliği gübre mevzuatında yasal bir çerçeveye kavuşturulan bu girdiler; humik maddelerden mikrobiyal inokulantlara kadar oldukça geniş bir yelpazeyi içine almaktadır (López-Serrano et al., 2026). Türkiye'de de özellikle 2000'li yıllardan itibaren bitki aktivatörleri ve mikrobiyal preparatlar kapsamında yaygınlaşan biyostimülantlar, kimyasal girdi bağımlılığını azaltan çevre dostu ve sürdürülebilir tarımsal üretim sistemlerinin önemli bir bileşeni durumuna gelmiştir (Külahtaş ve Çokuysal, 2016; Baran ve Erbaş Köse, 2022). Tohum primingi uygulamalarında kullanılan biyostimülantlar, kaynaklarına ve etki biçimlerine göre başlıca birkaç grupta toplanmaktadır.

Deniz yosunu ekstraktları (özellikle *Ascophyllum nodosum* ve *Ecklonia maxima*), bünyelerinde barındırdıkları doğal büyüme düzenleyiciler, betain, mannitol ve iz elementler sayesinde tohum çimlenmesini uyarmakta, kök gelişimini teşvik etmekte ve erken dönem su kısıtına karşı fizyolojik

koruma sağlamaktadır (Ma et al., 2022; López-Serrano et al., 2026). Leonardit veya organik kaynaklardan elde edilen humik ve fulvik asitler, tohum ve kök çevresinde katyon değişimini ile su tutma kapasitesini iyileştirerek fidenin su ve besin alımını kolaylaştırmaktadır. Amino asitler ve protein hidrolizatları ise hücresel düzeyde ozmotik dengenin korunmasına, antioksidan sistemlerin desteklenmesine ve kuraklık baskısı altındaki fidelerde metabolik dengenin sürdürülmesine katkıda bulunmaktadır (Rouphael ve Colla, 2020). Ayrıca çeşitli bitkisel özütler ile doğal bir biyopolimer olan kitosan; hücre zarı bütünlüğünü koruyarak ve savunma tepkilerini uyararak tohumların çimlenme gücünü desteklemektedir (Jatana et al., 2024; Wazeer et al., 2025).

Mikrobiyal biyostimülantlar grubunda yer alan bitki gelişimini teşvik eden rizobakteriler (PGPR) ve arbüsküler mikorizal mantarlar (AMF), tohum priminginde etkinliği sıklıkla araştırılan unsurlar arasındadır. *Bacillus*, *Pseudomonas* ve *Azospirillum* gibi yararlı bakteri cinsleri; büyüme düzenleyici maddelerin üretimi, fosfatın yarayışlı hâle getirilmesi ve salgıladıkları biyofilm matrisi sayesinde tohum çevresinde nem koruyucu mikro alanlar oluşturarak kuraklığın yıkıcı etkilerini hafifletmektedir (Naseem ve Bano, 2014; Ansari et al., 2021; Harsonowati et al., 2026). Mikorizal mantarlar ise kök yüzey alanını ve emilim kapasitesini belirgin biçimde artırarak bitkinin kısıtlı toprak nemine ve fosfor başta olmak üzere temel besin elementlerine ulaşmasını güvence altına almaktadır (Begum et al., 2019; Chandrasekaran, 2022). Bunların yanı sıra vermikompost özütleri ve poliaminler gibi organik kökenli diğer bileşikler de tohumların çimlenme enerjisini ve erken fide dayanıklılığını pekiştiren tamamlayıcı biyostimülant kaynakları olarak öne çıkmaktadır.

Tarla Bitkilerinde Uygulama Örnekleri

Biyostimülant destekli tohum primingi uygulamaları, kuraklık stresi altındaki tarla bitkilerinde çimlenme performansını ve erken fide gelişimini iyileştirmede geniş bir kullanım alanı bulmaktadır. Farklı bitki gruplarında yürütülen araştırmalar, bu uygulamaların türe ve genotipe özgü olumlu fizyolojik tepkiler ortaya çıkardığını göstermektedir. Tahıllar arasında özellikle buğday (*Triticum aestivum* L.), biyostimülant ve mikrobiyal tohum uygulamalarının en yoğun araştırıldığı türlerden biridir. Buğday tohumlarına uygulanan yararlı bakteri inokulasyonlarının kısıtlı toprak nemi koşullarında bitki gelişimini desteklediği, PEG ile simüle edilen kuraklık ortamında fide taze ağırlığı ile kök uzunluğunu artırdığı ve hücre zarı hasarını azalttığı belirlenmiştir (Li et al., 2020; Çığ et al., 2022). Benzer şekilde *Streptomyces* ve *Pseudomonas* suşları ile ekzopolisakkarit üreten rizobakterilerin salisilik asit gibi elisitörlerle birlikte uygulanması; buğdayda fotosentetik verimliliği, çözünür şeker ve protein birikimini koruyarak su açığı kaynaklı hasarları hafifletmiştir (Khan ve Bano, 2019; Ansari et al., 2021). Diğer serin iklim tahılı olan arpa (*Hordeum vulgare* L.) tohumlarında ise düşük dozda melatonin, osmotik ajanlar ve hidropriming uygulamalarının ortalama çimlenme süresini kısalttığı ve suboptimal nem şartlarında erken fide çıkış gücünü belirgin biçimde artırdığı bildirilmektedir (García-Cánovas et al., 2024; Janah et al., 2025).

Sıcak iklim tahıllarından mısırda (*Zea mays* L.), su stresi koşullarında biyostimülant destekli uygulamalar tohumun su alımını hızlandırmakta ve solmayı geciktirmektedir. Mısır tohumlarının giberellik asit ve melatonin ile muamele edilmesi, kuraklık altında çimlenme oranını %90'ın üzerine çıkarırken fide boyunu ve kök gelişimini desteklemiştir (Kumari et al., 2026). Ayrıca ekzopolisakkarit üreten PGPR suşları ve doğal bitki özütleri ile yapılan tohum uygulamalarının, mısır fidelerinde bağıl su içeriğini koruduğu ve kısıtlı sulama şartlarında erken dönem biyokütle kaybını önlediği saptanmıştır (Naseem ve Bano, 2014; Melo et al., 2026). Yağ bitkileri grubunda ayçiçeği (*Helianthus annuus* L.) tohumlarında hidropriming, osmopriming ve mikrobiyal destekli uygulamalar; çimlenme homojenliğini artırmakta, kök mimarisini güçlendirerek fidenin su kullanım etkinliğine katkı sağlamakta ve kuraklık stresine karşı çapraz tolerans oluşturmaktadır (Ceritoğlu et al., 2021; López-Serrano et al., 2026).

Yemeklik dane baklagiller ve endüstri bitkilerinde de biyostimülant destekli tohum primingi kritik avantajlar sağlamaktadır. Nohut (*Cicer arietinum* L.), mercimek ve fasulye tohumlarında *Bacillus* tabanlı mikrobiyal inokulasyonlar ile büyüme düzenleyicilerin birlikte kullanımı, kuraklık altında dokulardaki bağıl su içeriğini yükseltmiş, hücre zarı geçirgenliğini ve lipit peroksidasyonunu sınırlandırmıştır (Khan et al., 2019). Baklagillerde tohum primingi aynı zamanda nodülasyon ve biyolojik azot fiksasyonu süreçlerine de erken dönemde ivme kazandırmaktadır (Harsonowati et al., 2026). Soya fasulyesinde (*Glycine max* L.) doğal biyopolimer matrisleri ve yararlı mikroorganizmalarla yapılan tohum primingi işlemleri, kuraklık stresinde çimlenme hızını artırmış ve antioksidan enzim aktivitelerini uyararak fide canlılığını korumuştur (Almakas et al., 2025). Fiğ başta olmak üzere yem

bitkilerinde ise mikoriza (AMF) ve PGPR içeren mikrobiyal formülasyonlar, kök yüzey alanını ve besin yarayışlılığını artırarak erken dönemdeki su kısıtının hafifletilmesine ve tarla çıkışının desteklenmesine katkı sağlamaktadır (Begum et al., 2019; Baran ve Erbaş Köse, 2022).

Uygulamalara İlişkin Kısıtlar Ve Araştırma Gereksinimleri

Biyostimülant destekli tohum primingi uygulamaları tarla bitkilerinde kuraklık stresine karşı önemli kazanımlar sağlasa da yöntemin pratik tarımsal üretime aktarılmasında ve geniş alanlarda yaygınlaştırılmasında bazı temel kısıtlar ile araştırma gereksinimleri bulunmaktadır. Bu güçlüklerin başında, uygulanan yöntemlerin bitki türü ve genotipine bağlı olarak yüksek değişkenlik göstermesi gelmektedir. Aynı biyostimülant kaynağı veya priming süresi bir çeşitte çimlenme performansını ve erken fide canlılığını belirgin düzeyde teşvik ederken, farklı bir genotipte sınırlı kalabilmekte ya da tamamen etkisiz olabilmektedir (Khan ve Bano, 2019; Wazeer et al., 2025). Bu durum, uygulamaların genelleştirilmesini güçleştirmekte ve her bitki grubu için optimize edilmiş çeşide özgü uygulama protokollerinin geliştirilmesini zorunlu kılmaktadır.

Bir diğer önemli kısıt, biyostimülant konsantrasyonlarının ve uygulama sürelerinin standardize edilememesidir. Literatürde rapor edilen dozlar ve muamele süreleri oldukça geniş bir aralığa yayılmakta; optimum eşik değerinin altındaki konsantrasyonlar stres toleransını yeterince tetikleyemezken, aşırı dozlar fitotoksik etki oluşturabilmekte veya tohumun aşırı hidrasyonuna yol açarak kurutma sırasında embriyo hasarı riski yaratabilmektedir (García-Cánovas et al., 2024; Singh et al., 2025). Bunun yanı sıra, laboratuvar ve iklim odası koşullarında polietilen glikol (PEG) gibi kimyasal ajanlarla simüle edilen kuraklık denemelerinde elde edilen başarılı sonuçlar, tarla koşullarında her zaman aynı düzeyde sergilenememektedir. Sahadaki değişken toprak pH'sı, organik madde düzeyi, yerli toprak mikrobiyotasıyla rekabet ve öngörülemeyen iklim dinamikleri biyostimülantların etkinliğini doğrudan değiştirebilmektedir (Melo et al., 2026; López-Serrano et al., 2026). Bu nedenle kontrollü ortamlarda elde edilen verilerin çok lokasyonlu tarla denemeleriyle doğrulanması gerekmektedir.

Özellikle mikrobiyal kökenli biyostimülantlarda raf ömrü, formülasyon teknolojisi ve tohum yüzeyindeki bakteri ya da mantar canlılığının korunması önemli bir lojistik engel teşkil etmektedir (Harsonowati et al., 2026). Diğer taraftan priming işleminden geçmiş tohumların metabolik olarak yarı aktif durumda bulunması, bu tohumların depolama ömrünü kısaltmakta ve uzun süreli saklama şartlarında çimlenme gücünün hızla kaybolmasına neden olabilmektedir (Ceritoğlu et al., 2021). Son olarak, uygulamaların çiftçi ölçeğindeki maliyet-etkinliğini gösteren ekonomik analizlerin yetersizliği, yerel biyostimülantların tescil ve mevzuat süreçleri ile üretici düzeyindeki eğitim eksiklikleri yöntemin yaygınlaşmasını engellemektedir (Külahtaş ve Çokuysal, 2016). Bu araştırma gereksinimlerinin karşılanması ve mevcut kısıtların giderilmesi, biyostimülant destekli tohum priminginin sürdürülebilir tarımda güvenilir bir girdi olarak yer edinmesi açısından büyük önem taşımaktadır.

SONUÇ

Küresel iklim değişikliği ve artan kuraklık baskısı, tarla bitkileri yetiştiriciliğinde tohum çimlenmesi ve erken fide gelişimi evrelerini giderek daha riskli hâle getirmektedir. Bu derleme kapsamında incelenen güncel bilimsel bulgular; biyostimülant destekli tohum priminginin su kısıtı altında çimlenme yüzdesi, çıkış hızı, kök mimarisi ve erken dönem fide biyokütlesi üzerinde belirgin iyileşmeler sağladığını ortaya koymaktadır. Deniz yosunları, humik maddeler, amino asitler, kitosan, PGPR ve mikorizal mantarlar gibi biyostimülantların tohum primingine entegre edilmesi; dokularda bağıl su içeriğinin korunması, ozmotik dengeleyicilerin birikimi, antioksidan savunma mekanizmalarının uyarılması ve hücresel zar hasarlarının sınırlandırılması yoluyla bitkilerin kuraklık toleransını çok yönlü olarak güçlendirmektedir. Bu durum, özellikle kurak ve yarı kurak ekolojilerde yetersiz ve düzensiz tarla çıkışından kaynaklanan verim kayıplarının azaltılmasında yöntemi umut verici, çevreyle uyumlu ve sürdürülebilir bir ön ekim teknolojisi konumuna taşımaktadır.

Bununla birlikte, yöntemin sağladığı potansiyelin sahada kalıcı bir başarıya dönüşebilmesi için bazı temel uygulama kısıtlarının aşılması gerekmektedir. Biyostimülant etkinliğinin bitki tür ve genotipine göre belirgin farklılık göstermesi, standart bir uygulama yerine çeşide özgü optimum doz ve süre reçetelerinin belirlenmesini zorunlu kılmaktadır. Ayrıca laboratuvar ortamlarında elde edilen olumlu bulguların farklı toprak özellikleri ve değişken iklim koşullarını barındıran çok lokasyonlu tarla denemeleriyle teyit edilmesi, mikrobiyal formülasyonların tohum üzerindeki canlılık ve raf ömrünün uzatılması büyük önem taşımaktadır. Sonuç olarak, optimize edilmiş protokoller, geliştirilmiş

tohumculuk mevzuatı ve çiftçi düzeyinde yayım çalışmalarıyla desteklendiğinde biyostimülant destekli tohum primingi; su kısıtı altındaki tarla tarımında bitki çıkış güvencesini artıracak, sentetik girdi bağımlılığını azaltacak ve sürdürülebilir ürün güvenliğine kayda değer katkılar sunacaktır.

ÖZET
Kapari (*Capparis spinosa* L.), Capparaceae familyasına ait, başta Akdeniz Havzası olmak üzere kurak ve yarı kurak bölgelerde doğal olarak yetişen çok yıllık, dikenli bir çalı türüdür. Gıda ve geleneksel tıp alanlarında uzun süredir kullanılan bitki, son yıllarda fitokimyasal ve farmakolojik araştırmalara da konusu olmuştur. Kök, gövde, yaprak, çiçek tomurcuğu ve meyve gibi farklı organlarda flavonoitler, alkaloitler, glukosinolatlar, fenolik asitler, yağ asitleri ve steroller başta olmak üzere çeşitli biyoaktif barındırmaktadır. Literatür çalışmalarında kapari ekstrelerinin antioksidan, antidiyabetik, anti-inflamatuar, immünomodülatör, antimikrobiyal ve antikanser dâhil çeşitli biyolojik aktiviteler göstermektedir. Türkiye'de *Capparis* cinsinin *C. spinosa* ve *C. ovata* ile temsil edildiği, kaparinin kurak ve yarı kurak koşullara uyumu nedeniyle gıda, tarım ve arazi rehabilitasyonu bakımından ekonomik potansiyel taşımaktadır. Bu derlemede *C. spinosa'nın* botanik özellikleri, taksonomisi, coğrafi yayılışı, fitokimyasal ve besinsel özellikleri, farmakolojik aktiviteleri, geleneksel kullanımları, gıda işleme ve ekonomik önemi ile güvenlik profili literatür çerçevesinde ele alınmıştır. Ayrıca, çiçeklenme dönemi, nektar ve polen özellikleri, tozlaşma ilişkileri ve Türkiye'deki arı bitkisi çalışmaları dikkate alınarak *C. spinosa'nın* arı merası olarak değerlendirilme potansiyeli değerlendirilmiştir.
Anahtar Kelimeler *Capparis spinosa*; kapari; nektar; polen; arı merası; etnobotanik

ABSTRACT
Caper (*Capparis spinosa* L.), belonging to the *Capparaceae* family, is a perennial, spiny shrub species that grows naturally in arid and semi-arid regions, primarily in the Mediterranean Basin. Long used in food and traditional medicine, the plant has also become the subject of phytochemical and pharmacological research in recent years. It contains various bioactive compounds, mainly flavonoids, alkaloids, glucosinolates, phenolic acids, fatty acids, and sterols, in different organs such as roots, stems, leaves, flower buds, and fruits. Literature studies indicate that caper extracts exhibit various biological activities, including antioxidant, antidiabetic, anti-inflammatory, immunomodulatory, antimicrobial, and anticancer. Given that the genus *Capparis* is represented in Turkey by *C. spinosa* and *C. ovata*, caper holds economic potential in terms of food, agriculture, and land rehabilitation due to its adaptation to arid and semi-arid conditions. In this review, the botanical characteristics, taxonomy, geographical distribution, phytochemical and nutritional properties, pharmacological activities, traditional uses, food processing, economic importance, and safety profile of *C. spinosa* are discussed within the framework of the literature. Furthermore, considering the flowering period, nectar and pollen characteristics, pollination relationships, and bee flora studies in Turkey, the potential of *C. spinosa* to be evaluated as a bee pasture was assessed.
Keywords: *Capparis spinosa*; caper; nectar; pollen; bee pasture; ethnobotany.

GİRİŞ
Tıbbi bitkiler, insanlık tarihi boyunca en önemli tedavi kaynaklarından biri olarak kabul edilmiştir. Son yıllarda, düşük yan etki profiliyle birlikte farklı sağlık yararları sunmaları nedeniyle yenilebilir tıbbi bitkilerin sağlık üzerindeki etkilerine yönelik ilgi belirgin biçimde artmıştır (Nabavi vd., 2016). Bu bitkiler arasında *Capparis* L. cinsi, Capparaceae familyası içinde 250 ile 400 arasında değişen sayıda türü barındıran, Afrika, Asya, Akdeniz ve Amerika kıtalarının tropik ve subtropik bölgelerinde yaygın olarak bulunan bir bitki grubudur (Alsharif ve Boylan, 2025). Cins içerisinde en fazla bilinen ve ekonomik öneme sahip tür olan *Capparis spinosa* L., yaygın adıyla kapari, gıda ve geleneksel tıp alanında binlerce yıldır kullanılmaktadır. Arkeolojik kazılarda; Irak'ın Tell es-Sawwan yerleşiminde

(MÖ 5800) ve Çin'in Turpan bölgesindeki Yanghai mezarlarında (MÖ 2800) kapari tohumlarına rastlanmış olması, bitkinin insanlık tarihindeki köklü kullanımının bir kanıtı olarak değerlendirilmektedir (Chedraoui vd., 2017). Antik dönemde Dioskorides'in De Materia Medica adlı eserinde bitkinin "κάππαρις" adıyla anıldığı ve kendine özgü bir bitki olarak tanımlandığı bildirilmektedir (Christodoulou vd., 2022). Günümüzde kapari üzerine yapılan bilimsel çalışmalar; bitkinin zengin fitokimyasal içeriğini, çok yönlü farmakolojik etkilerini, geleneksel tıptaki kullanım alanlarını ve tarımsal-ekonomik potansiyelini ortaya koymaktadır.
Bu derlemenin amacı, bilimsel literatürden yararlanarak *Capparis spinosa* L.'nin botanik özellikleri, taksonomik durumu, coğrafi yayılışı (Türkiye'deki durumu dâhil), fitokimyasal bileşimi, besinsel özellikleri, farmakolojik aktiviteleri, geleneksel kullanım alanları, gıda işleme, tarımsal-ekonomik önemi, güvenlik profilini, türün çiçeklenme ve tozlaşma özellikleri ile mevcut arıcılık literatürü doğrultusunda arı merası olarak kullanılma potansiyelini ortaya koymaktır.

MATERYAL ve YÖNTEM

Bu çalışma; kaparinin botanik özellikleri, taksonomisi, coğrafi yayılışı, Türkiye'deki durumu, fitokimyasal içeriği, besinsel değeri, farmakolojik aktiviteleri, geleneksel tıpta kullanımı, gıda olarak önemi, tarımsal önemi, ekonomik önemi, arıcılık açısından önemi ve arı merası potansiyeli literatüre dayalı olarak incelenmiştir. Kaparinin incelenen özelikleri internet kaynakları ve veri tabanlarından yararlanılarak değerlendirilmiştir.
Bu çalışma; ilgili kaynakların taranması, kaynakların çeşitli açılardan değerlendirilmesi, yorumlanması ile kaparinin arıcılık için önemi ve arı merası olarak değerlendirilme potansiyelini ortaya koymaya odaklanmıştır.

Botanik Özellikleri ve Taksonomisi

Capparis spinosa L., kışın yapraklarını döken, çok yıllık bir çalı türüdür. Bitki dik, yarı yatık (precumbent) veya sarkık (pendulous) büyüme formunda gelişmektedir. Gövde dallanmamış ya da yoğun dallanmış biçimde, yeşil, kırmızı veya sarı renkte olup 4 metreye kadar uzayabilmektedir. Sürgünler kıvrımlı ya da düz, tüylü ya da tüysüz olabilmektedir (Chedraoui vd., 2017). Yapraklar oval-yuvarlak, etli yapıda olup, yaprak kulakçıkları (stipula) çoğunlukla dikene dönüşmüştür. Bitkinin *spinosa* (dikenli) adını almasının nedeni de budur (Alsharif ve Boylan, 2025).
Bitkinin yaşam döngüsü Akdeniz'de yaklaşık altı ay olup, mayıs ayında toprak yüzeyine yakın gelişen yeşil sürgünlerin oluşumuyla başlamaktadır. Çiçek tomurcukları sürgünler üzerinde; büyük, beyazdan pembemsi beyaza değişen renkte ve alacakaranlıkta açılıp gün doğumundan kısa süre sonra turgorunu kaybetmektedir (Christodoulou vd., 2022). Bu hızlı büyüme derin, geniş ve iletken bir kök sistemi gerektirmektedir. Bitkinin bu kök yapısı kayalık yarıklara, taşlık yamaçlara, eski duvarlara ve arkeolojik alanlara tutunabilmesini sağlayan karakteristik özelliklerinden biridir (Christodoulou vd., 2022; Annaz vd., 2022). Meyve, olgunlaştığında çatlayan, karpuzcuk biçiminde etli bir kapsül olup çok sayıda tohum içermektedir. Ayrıca tohumların yayılmasında karıncaların rolü olduğu bildirilmektedir (Yeğenoğlu ve Uz, 2011). *Capparis* cinsi, Capparaceae familyası içinde yer almakta ve ilk kez Carolus Linnaeus tarafından 1753 yılında Species Plantarum adlı eserde tanımlanmıştır (Chedraoui vd., 2017). *C. spinosa* grubunun morfolojik olarak yüksek değişkenlik göstermesi, tür ve alt tür düzeyinde taksonomik yorum farklılıklarına yol açmıştır. Fici (2014) tarafından Akdeniz'den Orta Asya'ya uzanan coğrafyada gerçekleştirilen taksonomik çalışmada, *C. spinosa* grubu içerisinde bir tür ve iki alt tür tanımlanmıştır (*C. spinosa* subsp. *spinosa* ve *C. spinosa* subsp. *rupestris*.).
Morfolojik yaklaşımların yalnızca nitel ve nicel vejetatif karakterlere dayanması, taksonun yanlış tanımlanmasına ve farklı varyetelerin hatalı sınıflandırılmasına neden olmuştur. Bu nedenle, moleküler verilerle desteklenen çalışmalar (örneğin AFLP – Amplified Fragment Length Polymorphism analizleri), morfolojik sınıflandırmaları tamamlayarak filogenetik ilişkilerin, farklı eko/biyotiplerin ve türün evrimsel eğilimlerinin aydınlatılmasına katkı sağlamıştır (Chedraoui vd., 2017).

Coğrafi Yayılışı ve Türkiye'deki Durumu

Capparis spinosa L., başta Güney Avrupa, Kuzey Afrika, Arap Yarımadası, Orta Doğu, Güneybatı ve Orta Asya olmak üzere geniş bir coğrafyada doğal olarak yayılış göstermektedir. Yayılış alanı doğuya doğru Çin, Nepal ve Hindistan'a, güneye doğru ise Madagaskar'a kadar uzanmaktadır (Alsharif ve Boylan, 2025; Sun vd., 2023). Bitki yükseltisi 3000 metreye kadar çıkan kayalık, kalkerli ve taşlık

arazilerde, eski duvarlarda ve yarı kurak habitatlarda kendiliğinden yetişebilmektedir. Dünya genelinde başlıca üretim alanları arasında Fas, İber Yarımadası'nın güneydoğusu, Türkiye ve İtalya'nın Pantelleria ile Salina adaları yer almaktadır. Türkiye'de *Capparis* cinsine ait doğal olarak yayılış gösteren iki tür bulunmaktadır: *Capparis spinosa* L. ve *Capparis ovata* Desf. (Bazı kaynaklarda *Capparis sicula* subsp. herbacea olarak da adlandırılmaktadır). Her iki türün de üçer varyetesi tanımlanmıştır (Yeğenoğlu ve Uz, 2011). Genel eğilim olarak *C. spinosa* varyeteleri ülkemizin batı ve güney kıyı bölgelerinde, *C. ovata* varyeteleri ise iç kesimlerde özellikle Doğu ve Güneydoğu Anadolu bölgelerinde doğal yayılış göstermektedir. *C. spinosa* çoğunlukla 300 metre rakıma kadar olan kıyı şeridinde bulunurken, *C. ovata* (*C. sicula* subsp. herbacea) daha karasal iklimin hâkim olduğu iç bölgelerde 1500-1800 metre rakıma kadar yayılış gösterebilmektedir. Türkiye'de *Capparis* türlerinin geniş bir coğrafyada doğal olarak bulunduğu bildirilmektedir. Derin ve yayılıcı kök sistemi nedeniyle kapari, erozyon kontrolü ve kurak veya ekonomik değeri düşük arazilerin değerlendirilmesi açısından da alternatif bir bitki olarak ele alınmaktadır.

Fitokimyasal İçeriği

Bitkinin kimyasal bileşimi; genotip, hasat zamanı, bitki organının büyüklüğü, çevresel koşullar ve muhafaza yöntemleri gibi çok sayıda faktöre bağlı olarak belirgin biçimde değişkenlik göstermektedir (Alsharif ve Boylan, 2025; Mohaddab vd., 2024). Başlıca fitokimyasal sınıflar; alkaloitler, flavonoitler, yağ asitleri, glukosinolatlar ve sterollerdir. Azotlu bileşikler grubunda yer alan alkaloitler, kaparinin özellikle kök kısmında yoğun biçimde bulunmakla birlikte diğer organlarda da tespit edilmiştir. Meyvelerden izole edilen kapparisin A, B ve C gibi alkaloitlerin yanı sıra stachydrine türevi bileşikler de tanımlanmıştır (Alsharif ve Boylan, 2025). Kapari, özellikle rutin, kersetin (quercetin) ve kaempferol glikozitleri başta olmak üzere yüksek düzeyde antioksidan flavonoitler içermektedir. Bu bileşikler meyve, yaprak ve tomurcuklarda değişen oranlarda bulunmakta olup, genellikle yapraklarda en yüksek konsantrasyonda tespit edilen flavonoitler öne çıkmaktadır (Mohaddab vd., 2024; Annaz vd., 2022). Kapari tohumları başta glukokapperin olmak üzere glukosinolat bileşikleri açısından zengin bir kaynaktır. Bu bileşiklerin enzimatik parçalanması sonucu oluşan metil izotiyosiyanat gibi ürünler bitkiye kendine özgü keskin kokuyu kazandırmakta ve aynı zamanda antimikrobiyal aktiviteye katkı sağlamaktadır (Annaz vd., 2022; Kdimy vd., 2022). Kapari tohum ve meyvelerinde oleik ve linoleik asit gibi doymamış yağ asitlerinin yanı sıra β-sitosterol gibi steroller ve tokoferoller tespit edilmiştir. Ayrıca bitkide karotenoitler (özellikle lutein), C vitamini ve çeşitli mineral maddeler de önemli miktarlarda bulunmaktadır (Annaz vd., 2022; Sun vd., 2023).

Besinsel Değeri

Kapari temel besin bileşenleri açısından da dikkat çekici bir potansiyele sahiptir. Meyvenin yüksek oranda nem, düşük oranda kül, orta düzeyde protein, düşük oranda yağ, kalsiyum, magnezyum, potasyum, sodyum, demir ve fosfor gibi önemli maddeleri barındırmaktadır. Mineral içeriği yetiştiricilik işlemleri, hasat zamanı ve meyve büyüklüğüne bağlı olarak değişkenlik göstermektedir (Sun vd., 2023; Annaz vd., 2022). Kapari meyvelerinin (kaper) karbonhidrat, diyet lifi, protein ve yağ içeriğinin yanı sıra orta düzeyde C vitamini taşıdığı bildirilmektedir (Mohaddab vd., 2024). Yaprak, tomurcuk ve çiçeklerde yapılan analizlerde yüksek düzeyde toplam karotenoit tespit edilmiş olup lutein baskın karotenoit bileşeni olarak öne çıkmaktadır. Tomurcuk ve çiçeklerde ise hem alfa- hem de gama-tokoferol formlarının önemli düzeylerde bulunduğu bildirilmiştir (Annaz vd., 2022). Bitki ayrıca K vitamini, bakır, E vitamini, magnezyum ve demir gibi diğer vitamin ve mineralleri de içermektedir (Annaz vd., 2022). Bu zengin besinsel profil, kaparinin yalnızca bir baharat/lezzet vericisi olarak değil, aynı zamanda çok yönlü bir gıda olarak da değerlendirilmesine olanak tanımaktadır.

Farmakolojik Aktiviteleri

Capparis spinosa L. ekstrelerinde antioksidan, antidiyabetik, anti-inflamatuar, immünomodülatör, antimikrobiyal, antikanser ve çeşitli diğer biyolojik aktivitelerinin incelendiği bildirilmektedir (Vahid vd., 2017; Nabavi vd., 2016). Kaparinin antioksidan etkisi, DPPH, FRAP ve ABTS gibi farklı testler ile değerlendirilmiş ve bu etkinin bitkideki toplam fenolik ve flavonoit içeriğiyle yakından ilişkili olduğu gösterilmiştir. Metanolik ekstrelerin, sulu ekstrelere kıyasla daha yüksek toplam fenol, flavonoit, alkaloit ve C vitamini içeriğine sahip olduğu ve buna paralel olarak daha güçlü antioksidan aktivite sergilediği bildirilmiştir (AlMousa vd., 2022). Yaprak ve kök ekstrelerinden LC-MS/MS ile karakterize

edilen rutin, resveratrol ve astragalin gibi bileşiklerin, DPPH, FRAP, ABTS ve CUPRAC test sistemlerinde belirgin radikal süpürücü aktivite göstermiştir. Kapari, geleneksel olarak başta İran olmak üzere birçok ülkede kan şekerini düşürücü bir bitki olarak kullanılmaktadır (Vahid vd., 2017). Streptozotosin ile diyabet oluşturulan fare deneylerinde kaparinin sulu ekstresinin; endojen glukoz üretimini azaltarak ve insülin duyarlılığını artırarak belirgin bir hipoglisemik etki gösterdiği ortaya konmuştur (Vahid vd., 2017). Önerilen antihiperglisemik mekanizmalar arasında ince bağırsaktan karbonhidrat emiliminin azaltılması, karaciğerde glukoneogenezin baskılanması, dokularda glukoz alımının artırılması ve beta hücrelerinin korunması/rejenerasyonu yer almaktadır (Vahid vd., 2017). Tip 2 diyabet hastalarında yürütülen çalışmada; kapari ekstresi takviyesinin metabolik parametreler üzerinde olumlu etkiler oluşturduğu bildirilmiştir (Vahid vd., 2019). Kaparinin içerdiği kersetin ve kaempferol gibi flavonoitlerin insülin duyarlılığını artırarak kan glukoz düzeyini düşürücü etki gösterdiği de ayrıca vurgulanmaktadır (Al-Raish vd., 2025). Kaparinin sulu ve metanolik ekstrelerinin; ödemi, immün hücre infiltrasyonunu ve çeşitli inflamatuar belirteçleri azaltarak anti-inflamatuar etki gösterdiği bildirilmiştir (Alsharif ve Boylan, 2025). Kapari yağının siklooksijenaz (COX-1 ve COX-2) enzimleri üzerinde; inhibitör etki gösterdiği, kapari ekstresinin belirli sitokinlerin gen ifadesini düzenleyerek genel olarak anti-inflamatuar bir bağışıklık oluşturduğu bildirilmiştir (Annaz vd., 2022). Farklı coğrafi kökenlere ait kapari meyvelerinden elde edilen ekstrelerin lipopolisakkarit ile uyarılmış inflamatuar hücre modellerinde belirgin anti-inflamatuar aktivite sergilediği ve bu aktivitenin coğrafi kökene bağlı olarak farklılaştığı bildirilmiştir (Alsharif ve Boylan, 2025). Kapari ekstreleri çok sayıda bakteri ve mantar türüne karşı antimikrobiyal etki göstermektedir. Metanolik ve sulu ekstrelerin çeşitli Gram-pozitif ve Gram-negatif bakteri suşlarına karşı inhibitör etkisi bildirilmiş olup bu etkinin ekstredeki fenolik ve flavonoit içeriğiyle ilişkili olduğu bildirilmiştir (AlMousa vd., 2022). Yaprak uçucu yağının; çoğunlukla dimetil trisülfit, dimetil tetrasülfit ve metil izotiyosiyanat gibi kükürt içeren bileşiklerden oluştuğu ve bu bileşenlerin Listeria monocytogenes, Staphylococcus aureus, Escherichia coli, Salmonella ve Pseudomonas gibi gıda kaynaklı patojenlere karşı etkili olduğu, bu özelliğin kaparinin doğal bir gıda koruyucusu olarak potansiyel kullanımına işaret edilmektedir (Mohaddab vd., 2024). Kapari ekstreleri çeşitli kanser hücre hatları üzerinde sitotoksik ve apoptotik etkiler göstermektedir. Kolorektal kanser (HCT-116), prostat kanseri (PC3), mide kanseri (SGC-7901), meme kanseri (MCF-7) ve hepatoselüler karsinom (HepG2) hücre hatlarında yürütülen çalışmalarda, kapari ekstrelerinin doz bağımlı biçimde hücre canlılığını azalttığı ve apoptozu tetiklediği bildirilmiştir (Kdimy vd., 2022; Alsharif ve Boylan, 2025). Prostat kanseri hücrelerinde yürütülen bir çalışmada, kapari metanol ekstresinin Bcl-2 proteinini baskılayıp Bax proteinini artırarak mitokondriyal apoptotik yolağı aktive ettiği, koloni oluşumunu ve hücre göçünü belirgin biçimde azalttığı, bu etkilerinde ekstrede bulunan kersetin ve kaempferolün rol oynadığı in siliko doking analizleriyle desteklenmiştir. Ayrıca kaparinin doksorubisin kaynaklı kardiyotoksisiteye karşı kardiyomiyoblast hücrelerini koruyucu etki gösterdiği de bildirilmiştir (Alsharif ve Boylan, 2025). Yukarıda sayılan başlıca etkilerin yanı sıra kaparinin hepatoprotektif, kardiyoprotektif, antihipertansif, anti-alerjik ve antihistaminik, antiviral, anti-Helikobakter pylori, antiparaziter, antimutajenik, melanogenez uyarıcı ve böcek öldürücü (insektisidal) gibi çok çeşitli farmakolojik etkileri bulunmaktadır (Nabavi vd., 2016; Sun vd., 2023).

Geleneksel Tıpta Kullanımı

Capparis spinosa L., Greko-Arap, Çin, İran ve Ayurveda tıp sistemleri başta olmak üzere dünyanın birçok bölgesinde geleneksel tıbbın önemli bitkilerinden biri olarak kabul edilmektedir (Annaz vd., 2022). İran geleneksel tıbbında kaparinin kök ve tomurcuklarının; felç, uyuşukluk, eklem ağrıları ve siyatalji gibi rahatsızlıkların tedavisinde, yaprak veya kök kabuğunun çiğnenmesinin ise diş ağrısını hafifletmek amacıyla kullanıldığı bildirilmektedir. Meyvelerin ve tuzlanmış köklerin müshil (laksatif) olarak, sirke ve balla hazırlanan kaparinin ise karaciğer tıkanıklığı ve böbrek taşlarının tedavisinde kullanıldığı belirtilmektedir. Fas'ta kapari diyabet kontrolü ve tedavisinde geleneksel olarak tüketilen bir bitkidir. Tunus'ta meyve, tohum ve yapraklarının çeşitli rahatsızlıklarda kullanıldığı bildirilmektedir (Annaz vd., 2022). Türkiye'de bitki bölgelere göre kapari, gebre otu, gevil, kebere, geyil, bubu ve şebellah gibi farklı yerel adlarla anılmaktadır. Çiçek tomurcukları, meyvesi ve kök kabuğunun idrar söktürücü, kabız giderici ve kuvvet verici özelliklere sahip olduğu geleneksel bilgi olarak aktarılmaktadır (Yeğenoğlu ve Uz, 2011).

Gıda İşleme, Tarımsal ve Ekonomik Önemi

Kaparinin ekonomik değerinin temelini açılmamış çiçek tomurcuklarının (kaper) gıda amaçlı kullanımı oluşturmaktadır. Bu şekilde işlenen kaper, salamura ya da sirkeli konserve formunda uluslararası pazarlarda ticareti yapılan bir ürün hâline gelmektedir (Sun vd., 2023; Mohaddab vd., 2024). Türkiye'de kapari, geleneksel olarak doğadan toplanan yabani bitkilerden elde edilmekte olup ihracat ve işlenmiş ürün talebi nedeniyle ekonomik önem taşımaktadır. Kaparinin kurak ve yarı kurak koşullara olan yüksek toleransı; iklim düzensizlikleri etkilerinin giderek belirginleştiği Doğu Akdeniz ülkelerinde alternatif ve sürdürülebilir bir tarım ürünü olarak öne çıkmasını sağlamaktadır (Chedraoui vd., 2017). Derin kök sistemi sayesinde toprak erozyonunun önlenmesinde etkili bir bitki olarak da değerlendirilen kapari, normal tarım bitkilerinin yetişemediği güneye bakan eğimli arazilerde yetiştirilerek hem kırsal alanlarda istihdam yaratılmasına hem de ihracat gelirlerinin artırılmasına katkı sağlayabilecek bir potansiyele sahiptir.

Bazı çalışmalar kapari ekstrelerinin akut toksisite açısından düşük riskli olduğunu, bazı hayvan deneyli çalışmalarında akut toksisite belirtisi gözlenmediği bildirilmiştir (Sun vd., 2023; Annaz vd., 2022). Mevcut toksisite verilerinin sınırlı sayıda çalışmaya dayanması nedeniyle; özellikle uzun süreli kullanım, gebelik-emzirme dönemi ve olası ilaç etkileşimleri açısından daha kapsamlı klinik ve preklinik güvenlik çalışmalarına ihtiyaç duyulduğu belirtilmelidir.

Arıcılık Açısından Önemi ve Arı Merası Potansiyeli

Capparis türleri özellikle Akdeniz ve yarı kurak iklim kuşaklarında arıcılık açısından değerlendirilen bitkiler arasındadır. *C. spinosa*'nın arı merası olarak önemini değerlendirmek için çiçeklenme dönemi, nektar ve polen üretimi, tozlaşma ilişkileri ve balın kimyasal özellikleri birlikte ele alınmalıdır. Kapari çiçeklerinin renk, koku ve gece/alacakaranlıkta açılma özellikleri tozlaştırıcılarla etkileşim açısından dikkat çekmektedir. Eisikowitch vd. (1986), *Capparis* türlerinde nektar ve polen miktarının ekolojik koşullara ve taksona göre değişebildiğini bildirmiştir. Petanidou vd. (1996), *C. spinosa* nektarının hacim, şeker ve amino asit bileşiminin çiçeğin yaşı ve lokasyona göre değiştiğini göstermiştir. Zhang ve Tan (2009), erkek ve hermafrodit çiçeklerde polen üretimi ile nektar özelliklerinin farklılaşabildiğini; Kantsa vd. (2022) ise çiçek rengi ve kokusunun tozlaştırıcı etkileşimleriyle ilişkili olabileceğini bildirmiştir. Bu bulgular, *C. spinosa*'nın tozlaştırıcılar açısından kaynak sağlayabildiğini desteklemektedir. Bal arısı takviyeli doğal tozlaşmada salkım başına ortalama meyve tutum sayısının 4,36, yalnızca bal arıları ile yapılan tozlaşmada 3,77 ve doğal tozlaşmada ise 2,2 olduğu tespit edilmiştir. Çimlenme yüzdeleri, toplam şeker, ortalama meyve ağırlığı, sürgün uzunluğu ve fide uzunluğu, tüm uygulamalar arasında en yüksek bal arısı takviyeli doğal tozlaşma durumunda görülmüştür (Bhatnagar vd., 2023). Tripodi vd. (2025) tarafından *C. spinosa* balının aroma ve duyusal özelliklerinin karakterize edilmesi, türün bal üretimi açısından da araştırılabilir bir kaynak olduğunu göstermektedir. Kapari kuraklığa dayanıklılığı nedeniyle arı merası planlamasında değerlendirilebilecek türlerden biridir. Bununla birlikte, arı merası kurulumu açısından yalnızca nektar/polen varlığı değil; çiçeklenme yoğunluğu, süreklilik, arı ziyaret sıklığı, bal verimi ve yerel iklim koşulları da dikkate alınmalıdır. Kaparinin erozyon kontrolü ve marjinal arazilerin değerlendirilmesi amacıyla kullanılabilmesi, bu tür alanlarda arıcılık amaçlı bitkilendirme ile birlikte ele alınabilecek ek bir avantajdır (Chedraoui vd., 2017; Isagaliev vd., 2022). Türkiye'de farklı floristik araştırmalarda kaparinin bal arılarının yararlanabileceği bitkiler arasında kaydedildiği görülmektedir. Yozgat florası, Artvin, Bitlis ve Düzce'deki çalışmalar ile Türkiye'deki geleneksel arıcılık üzerine yapılan etnobotanik değerlendirmeler; kaparinin nektar ve/veya polen kaynağı olarak kayda geçtiğini göstermektedir (Taştan, 2021; Akyıldırım Beğen vd., 2025; Görhan ve Öztürk, 2021; Kanoğlu vd., 2023; Atsay ve Çakır, 2022).

Ancak bu floristik kayıtlar kaparinin her bölgede başlıca veya sürekli nektar kaynağı olduğunu tek başına kanıtlamaz. Türkiye'nin farklı ekolojik bölgelerinde arı ziyaretleri, nektar/polen verimi ve bal veriminin birlikte ölçüldüğü alan çalışmalarına ihtiyaç vardır.

SONUÇ VE ÖNERİLER

Capparis spinosa L.'nin kurak ve yarı kurak koşullara uyumu, çeşitli fitokimyasal bileşenleri, gıda amaçlı kullanımı ve araştırılan biyolojik aktiviteleri nedeniyle çok yönlü bir bitkidir. Farklı kullanım alanları, kimyasal içeriği ve yararları göz önünde bulundurulduğunda kaparinin hem tarımsal açıdan hem de arıcılık açısından önemli bir potansiyel taşıdığı görülmektedir. Türkiye'de *C. spinosa* ve *C. ovata*'nın doğal yayılış göstermesi, bu türlerin kurak ve yarı kurak alanların değerlendirilmesinde

kullanılma potansiyeline sahip olduğunu göstermektedir. Arıcılık açısından mevcut çalışmalar, *C. spinosa*'nın nektar ve polen kaynağı olabildiğini ve *C. spinosa* balının karakterize edilebildiğini göstermektedir. Ayrıca türün arı merası olarak yaygınlaştırılmasına ilişkin önerilerin yerel fenoloji, nektar/polen verimi, arı ziyaret sıklığı ve bal verimi verileriyle desteklenmesi oldukça önemlidir. Bu nedenle farklı bölgelerde kapari temelli arı merası denemelerinin yapılması ve elde edilen balın melissopalinolojik ve kimyasal özelliklerinin belirlenmesi önem taşımaktadır.

ÖZET
Mısır (*Zea mays* L.) dünya genelinde geniş alanlarda yetiştirilen ve üreticiler tarafından yoğun olarak tercih edilen tahıllardan biridir. Rüzgarla tozlaşan (anemofil) bir tür olmasına karşın erkek çiçek salkımlarından (püskül) ürettiği önemli miktardaki polen sayesinde bal arıları (*Apis mellifera* L.) başta olmak üzere birçok arı türü için önemli bir polen kaynağıdır. Bu derlemede; mısırın çiçeklenme biyolojisi, polen üretim kapasitesi, arılar tarafından toplanma davranışı, poleninin besinsel (özellikle protein ve amino asit) değeri, mısır tarımında yaygın kullanılan tohum ilaçlamalarının ve transgenik çeşitlerin arı sağlığına etkileri, mısır üretiminin arı merası çeşitliliği ve koloni beslenme dinamikleri üzerindeki etkileri ile mısırdan elde edilen yüksek fruktozlu mısır şurubunun arı beslemesindeki kullanımı literatür ışığında değerlendirilmiştir. Mısır nicelik olarak zengin ancak nitelik olarak sınırlı bir polen kaynağıdır. Tarımsal uygulamalar nedeniyle bal arısı sağlığı açısından hem fırsat hem de risk barındırmaktadır. Sonuç olarak, mısırın arı merası olarak potansiyeli tek başına değil, çiçeklenme dönemi dışında tamamlayıcı nektar ve polen kaynaklarının sağlanması ve pestisit maruziyetinin azaltılmasıyla birlikte değerlendirildiğinde önemli hale gelmektedir.
Anahtar Kelimeler: ***Z****ea mays*, beekeeping, bee pasture, pollen source, *Apis mellifera*

ABSTRACT
Maize (*Zea mays* L.) is one of the cereals grown over wide areas globally and heavily preferred by producers. Although it is a wind-pollinated (anemophilous) species, thanks to the significant amount of pollen it produces from its male inflorescences (tassels), it serves as an important pollen source for many bee species, primarily honey bees (*Apis mellifera* L.). In this review; maize's flowering biology, pollen production capacity, foraging behavior by bees, nutritional value of its pollen (especially protein and amino acids), the impacts of seed treatments and transgenic varieties widely used in maize cultivation on bee health, the effects of maize production on bee forage diversity and colony nutrition dynamics, and the use of high-fructose corn syrup derived from maize in bee feeding have been evaluated in the light of the literature. Maize is a rich pollen source quantitatively, but limited qualitatively. Due to agricultural practices, it harbors both opportunities and risks in terms of honey bee health. In conclusion, the potential of maize as a bee forage becomes significant when evaluated not on its own, but together with the provision of complementary nectar and pollen sources outside the flowering period and the reduction of pesticide exposure.
Keywords: Zea mays, apiculture, bee pasture, pollen source, Apis mellifera, neonicotinoid

GİRİŞ
Mısır (*Zea mays* L.) buğdaygiller (Poaceae) familyasına ait, tek yıllık, C4 fotosentez metabolizmasına sahip bir bitki olup dünya genelinde buğday ve pirinçle birlikte en fazla üretilen üç tahıldan biridir. İnsan ve hayvan beslenmesinde, nişasta, biyoyakıt ve endüstriyel şeker (yüksek fruktozlu mısır şurubu) üretiminde kullanılması nedeniyle ekim alanı son yıllarda hızla genişlemiştir. Bu dönüşüm, tarım alanlarında yaşayan veya bu alanlara komşu konumlanan bal arısı (*Apis mellifera* L.) kolonileri açısından hem doğrudan hem de dolaylı sonuçlar doğurmaktadır.

Arıcılık literatüründe bitkiler geleneksel olarak nektar bitkileri ve polen bitkileri olmak üzere iki temel kategoriye ayrılır. Mısır, rüzgarla tozlaşan (anemofil) bir tür olduğu için böcek çekici nektar üretmez; ancak erkek çiçek salkımı olan püskülden (tassel) kısa bir dönemde inanılmaz miktarda polen üretmektedir. Bu özelliği, mısırı klasik anlamda bir "bal bitkisi" olmaktan çıkarırken, bal arıları başta olmak üzere birçok arı türü için önemli bir polen kaynağına dönüştürmektedir (Höcherl ve ark., 2012; Chantarudee ve ark., 2012). Nitekim tarımsal üretimde polen tuzakları kullanılarak yapılan çalışmalar,

mısırın çiçeklenme döneminde arı kovanlarına giren toplam polenin önemli bir kısmının mısır kaynaklı olduğunu ortaya koymaktadır. Bununla birlikte, mısırın arıcılık açısından değerlendirilmesi yalnızca polen bolluğu üzerinden yapılamaz. Mısır poleninin protein ve esansiyel amino asit içeriği, birçok yabani ve kültür bitkisininkine kıyasla düşüktür (Roulston ve ark., 2000; Pamminger ve ark., 2019). Ayrıca modern mısır tarımında yaygın olarak kullanılan neonikotinoid grubu sistemik insektisitlerle kaplı tohumlar, ekim sırasında ortaya çıkan toz bulutu yoluyla arı ölümlerine ve kronik zehirlenmelere yol açabilmektedir (Krupke ve ark., 2012; Tsvetkov ve ark., 2017). Bir diğer madde ise, mısır ve soya gibi tek yıllık endüstriyel bitkilerin hâkim olduğu üretim alanlarında arı kolonilerinin mevsim içinde yaşadığı ziyafet-kıtlık dinamiğidir; kısa süreli bol kaynak dönemlerini uzun kıtlık dönemleri izlemektedir (Dolezal ve ark., 2019).

Bu derlemenin amacı; mısırın (*Zea mays* L.) arıcılık açısından önemini ve arı merası olarak kullanılma potansiyelini, botanik ve çiçeklenme biyolojisini, polen kalitesini, tarımsal uygulamaların arı sağlığına etkilerini, üretim ölçeğinde arı merası dinamikleri ve mısır kaynaklı ürünlerin arı beslemesindeki yerini incelemektedir.

MATERYAL VE YÖNTEM

Bu çalışma; mısır (*Zea mays* L.) yetiştiriciliği, kalitesi, fiziksel, kimyasal özelikleri, yetiştiricilik uygulamaları, döllenme biyolojisi ve mısır-arı ilişkilerinin literatüre dayalı incelenmesi ve değerlendirilmesi ile oluşturulmuştur. Mısırın genel özelikleri ve mısır-arı ilişkileri konusundaki internet kaynaklarından ve veri tabanlarından yararlanılmıştır. Bu çalışma ilgili kaynakların taranması, kaynakların çeşitli açılardan değerlendirilmesi, yorumlanması ve sentezlenmesi ile mısırın arıcılık için önemi ve arı merası olarak değerlendirilme potansiyelini ortaya koymaya odaklanmıştır.

BULGULAR ve TARTIŞMA

Mısırın Botanik Özellikleri ve Çiçeklenme Biyolojisi

Mısır, tek gövdeli, 1,5-3 metre boylanabilen, monoik (tek evcikli) bir bitkidir. Erkek çiçek topluluğu bitkinin tepe noktasında yer alan püskül (tassel) şeklinde, dişi çiçek topluluğu ise gövde üzerindeki yaprak koltuklarında oluşan koçan (mazorca) şeklindedir. Koçanın ucundan dışarı sarkan uzun, ipliksi stigma yapıları (silk/tepecik iplikçikleri) polen alıcı yüzeyi oluşturur. Bu yapılar silk çıkışından sonra günler boyunca polen almaya elverişli kalabilmekte, tepecik yüzeyindeki trikom (tüycük) yoğunluğu ise çeşide göre değişerek polen tutma etkinliğini belirlemektedir (Anderson ve ark., 2004). Bitkinin erkek ve dişi çiçeklerinin genellikle farklı zamanlarda olgunlaşması (protandri), kendine döllenme oranını düşürerek çapraz tozlaşmayı teşvik etmektedir; buna karşın silklerin polen alıcılığı çoğunlukla püskülden polen saçılımı başlamadan önce devreye girmektedir (Anderson ve ark., 2004). Mısır, tipik bir anemofil bitkidir. Anemofil (rüzgarla tozlaşan) türlerde, hedefe ulaşan polen oranının düşük olmasını telafi etmek ve tozlaşma başarısını şansa bırakmamak amacıyla orantısız derecede yüksek miktarda polen üretilmesi stratejisidir (Bochynek ve Burd, 2024). Mısır bu stratejinin tarımsal açıdan en belirgin örneklerinden biridir. Bireysel bir mısır bitkisinin püskülü döllenme için gerekli minimum miktarın kayda değer ölçüde, ortalama olarak milyonlarca polen tanesi üretebilmektedir. Bu aşırı üretim genel olarak mısırda pollen kaynağının kısıtlayıcı bir etken olarak görülmemesinin başlıca nedenidir (Westgate ve ark., 2003). Bir tek bitkinin püskülünden polen saçılımı genellikle 5-6 gün sürerken, tarla düzeyinde çeşit ve çevre koşullarına bağlı olarak toplam çiçeklenme süresi 2-14 gün arasında değişebilmektedir (Westgate ve ark., 2003; Wang ve ark., 2022). Bu yoğun üretim rüzgarla taşınma sırasında meydana gelen kayıpları telafi etmeye yöneliktir. Ayrıca üretim alanı açısından değerlendirildiğinde, çiçeklenme döneminde havada yoğun bir polen bulutu oluşmasına neden olur.

Bu polen bolluğunun zamanlaması arıcılık açısından kritik öneme sahiptir. Mısır tarlalarının çiçeklenme dönemi (genellikle yaz ortası, temmuz-ağustos ayları), birçok bölgede diğer kültür bitkilerinin çiçeklenmesinin sona erdiği ve doğal florada da nektar/polen akışının azaldığı bir döneme denk gelmektedir. Bu nedenle mısır tarımsal üretimde mevsimsel kıtlık dönemi olarak adlandırılan kritik bir zaman aralığında devreye giren, geçici fakat önemli bir polen kaynağı işlevi görebilmektedir (Höcherl ve ark., 2012; Deveci ve ark., 2015).

Mısırın Bal Arıları İçin Polen Kaynağı Olarak Değerlendirilmesi

Bal arıları, çiçeklenme döneminde mısır tarlalarını yoğun biçimde ziyaret ederek polen toplarlar. Brezilya'da yürütülen bir tarla denemesinde; bal arılarının mısır püskülündeki erkek çiçeklerden yoğun

biçimde polen topladığı ve mısır poleninin özellikle diğer polen kaynaklarının kıt olduğu dönemlerde arılar için önemli bir besin kaynağı olarak değerlendirildiği gösterilmiştir (Malerbo-Souza, 2011). ABD'de yürütülen çalışmasında; bal arılarının mısır poleni toplama etkinliğinin sabah saatlerinde (yaklaşık 09:00-10:00) zirveye ulaştığı belirlenmiş, tarımsal ilaçlama zamanlamasının arı maruziyeti açısından önemine işaret ettiği vurgulanmıştır (Mason ve Tracewski, 1982). Almanya'da yürütülen bir çalışmada ise mısırın yoğun biçimde kullanılan bir polen kaynağı olduğu, buna karşın arıların mısır poleni için kat ettiği ortalama mesafenin diğer polen kaynaklarına kıyasla daha kısa kaldığı ve mısır ekim alanı genişledikçe mısır poleni toplayan arı oranının orantılı biçimde artmadığı bildirilmiştir (Danner ve ark., 2014). Tayland'da *Apis mellifera* kolonilerinden toplanan polenler ile tarladan toplanan polenlerin karşılaştırılması sonucu; arı tarafından işlenmiş polenin biyotin, invert şeker, A vitamini, beta-karoten gibi besin bileşenleri açısından zengin olduğu ve serbest radikal süpürücü aktivitesinin tarladaki polenden 28 kat daha fazla olduğu bulunmuştur (Chantarudee ve ark., 2012). Tayland'daki ticari arı poleni üretiminde de mısır (*Zea mays*), kolza, çay ağacı, lotus gibi bitkilerle birlikte başlıca on bir polen kaynağından biri olarak sayılmakta; yılda 700 tonu aşan ticari arı poleni üretiminin önemli bir bölümü bu kaynaklardan elde edilmektedir. Bu durum, mısırın yalnızca koloni içi beslenme değil, ticari arı poleni üretimi için de kullanıldığını ortaya koymaktadır. Polenin besin değeri değerlendirilirken en sık kullanılan gösterge ham protein içeriğidir. Polen; bal arısı kolonisinde larva gelişimi, hipofarengeal bez fonksiyonu ve genel bağışıklık için ana protein kaynağıdır. Roulston, Cane ve Buchmann (2000), 93 bitki familyasından 377 türü incelendiği çalışmada; polen protein içeriğinin bitki filogenisi ile güçlü biçimde ilişkili olduğu ve zoofil türlerin anemofil türlerden istatistiksel olarak daha zengin protein içermediği bildirilmektedir. Pamminger ve ark. (2019) tarafından yürütülen derlemede, mısır ve ayçiçeğinin, arı tarafından ziyaret edilen tarımsal bitkiler arasında ham protein içeriği en düşük polen kaynakları arasında yer aldığı belirtilmiştir. Höcherl ve ark. (2012) tarafından yapılan çalışmada; mısır poleninde histidin amino asidinin belirgin biçimde düşük olduğunu, buna karşın diğer tüm esansiyel amino asitlerin miktarının polifloral karışıma göre daha yüksek çıktığını, mısır poleninin genel kabul edilenin aksine tamamen değersiz olmadığını, ancak dengeli bir amino asit profili sunmadığı için tek başına yeterli bir protein kaynağı oluşturmadığını göstermektedir. Fransa'da arı kolonilerinin mevsim boyunca topladığı polen karışımlarının koloni sağlığı (işçi arı hayatta kalma oranı ve hipofarengeal bez gelişimi) üzerindeki etkisini çalışmada; polen karışımlarının çoğunun arı sağlık göstergeleri üzerinde benzer olumlu etkiye sahip olduğu, buna karşın temmuz sonunda toplanan ve yoğun biçimde mısır poleni barındıran karışımın arının hayatta kalma oranı ve arı fizyolojisi üzerinde belirgin olumsuz sonuç doğurduğu; bu dönemin mısırın kitlesel çiçeklenme dönemine denk geldiği bildirilmiştir (Di Pasquale ve ark., 2016).Yukarıdaki bulgular birlikte değerlendirildiğinde, mısırın arıcılık açısından nicelik olarak zengin, nitelik olarak sınırlı bir polen kaynağı olduğu söylenebilir. Mısır tarlalarına yakın konulan kolonilerde toplam polen miktarı artar, ancak beslenme kalitesi diğer kaliteli polen kaynaklarının (baklagiller, Asteraceae, Brassicaceae vb.) mevcudiyetine bağlı kalmaya devam eder.

Mısır Tarımında Kullanılan Uygulamaların Arı Sağlığına Etkileri

Mısırın arı merası potansiyeli değerlendirilirken yalnızca bitkinin doğal polen değeri değil, aynı zamanda modern mısır tarımında standart hale gelmiş agronomik uygulamaların arı sağlığı üzerindeki etkileri de göz önünde bulundurulmalıdır. Neonikotinoid grubu sistemik insektisitlerin bal arıları ve diğer polinatörler üzerindeki etkilerine ilişkin çalışmada; insektisitlerin tohum kaplaması yoluyla toksik maruziyet yollarını, laboratuvar koşullarında gözlenen letal ve subletal etkileri ve polinatör ürünlerindeki kalıntı düzeylerini belirtilmiştir (Godfray ve ark., 2014). Amerika başta olmak üzere birçok ülkede ekilen mısır tohumlarının büyük bölümü tohumu toprak kökenli zararlılardan korumak amacıyla neonikotinoid grubu sistemik insektisitler ile kaplanmaktadır (Lin ve ark., 2021). Tohum kaplamasının pnömatik ekim makinelerinde sürtünme yoluyla aşınması ile insektisit yüklü ince bir tozun havaya karışmasına yol açar; bu toz bulutu ekim alanının çevresine ve civardaki çiçekli bitkilere taşınarak arı ölümüne neden olmaktadır (Lin ve ark., 2021; Samson-Robert ve ark., 2017). Krupke ve ark. (2012) tarafından yapılan çalışmada; mısır ve soya ekim alanlarına komşu arılarda ve kovan çevresindeki bitkilerde neonikotinoid kalıntılarının tespit edildiği bildirilmiştir. Krupke ve ark. (2017), Indiana eyaletinde ekim sırasında oluşan neonikotinoid tozunun tarla kenarından 100 metre uzaklıktaki çiçeklere kadar gidebildiğini, arı kolonilerinin büyük çoğunluğunun mısır ekimi sırasında öldürücü dozlara maruz kalmasına rağmen bu tohum ilaçlamalarının tutarlı bir bitki verim artışı sağlamadığını bildirmiştir. Long ve Krupke (2016) tarafından yapılan çalışmada; arıların neonikotinoid maruziyetinin

yalnızca mısır ekim dönemiyle sınırlı olmadığı, yabani bitkilerin de büyüme dönemi boyunca neonikotinoid kalıntısı taşıdığı ve kirlenmenin toprak ve yeraltı suyu yoluyla civar bitkilere taşındığını bildirilmiştir. Tsvetkov ve ark. (2017), mısır tarlalarına yakın kolonilerin sezonun büyük bölümünde (3-4 ay) neonikotinoidlere kronik olarak maruz kaldığını; bu maruziyetin işçi arı ölüm oranını artırdığını, sosyal bağışıklığı zayıflattığını ve zaman içinde anasız kalma oranını yükselttiğini bildirmiştir. Kanada'nın Québec eyaletinde yürütülen bir çalışmada; mısır tarımının yoğun olduğu bölgelerdeki kolonilerde günlük arı ölüm sayısının, mısır ekilmeyen bölgelerdeki kolonilere kıyasla 3,5 kat daha yüksek olduğunu, ölen arılarda çok sayıda farklı tarımsal pestisit kalıntısının aynı anda tespit edildiği bildirilmiştir (Samson-Robert ve ark., 2017). Bu bulgular birlikte değerlendirildiğinde, mısır tarımının modern, tohum-kaplama temelli koruma stratejisinin, bitkinin sunduğu polen kaynağı potansiyelini önemli ölçüde gölgeleyen bir risk faktörü oluşturduğu ortaya çıkmaktadır.

Böcek zararlılarına karşı dayanıklılık sağlamak amacıyla Bacillus thuringiensis bakterisinden alınan Cry protein genlerini taşıyan mısır çeşitleri, dünya genelinde yaygın olarak ekilmektedir.

Duan ve ark. (2008) tarafından yapılan çalışmada; Bt mısır ve pamuk çeşitlerinde kullanılan Cry proteinlerinin laboratuvar koşullarında larva ve erişkin bal arılarına zarar vermediği bildirilmiştir. Hendriksma ve ark. (2013), Bt mısır poleniyle beslenen arılarda hayatta kalma oranı, vücut ağırlığı ve polen sindirim oranı bakımından konvansiyonel mısır çeşitleriyle beslenenlere kıyasla anlamlı bir fark bulmamıştır. Aynı çalışmada, tam gelişmiş işçi arı larvalarının sindirim sistemlerinde 1720-2310 adet mısır polen tanesi (larva başına yaklaşık 1,52-2,04 mg polen) tespit edilmiştir. Bu polenlerin yaklaşık %74,5'inin tamamen, %23,3'ünün kısmen sindirildiği, yalnızca %2,2'sinin sindirilmeden kaldığı belirlenmiştir.

Bu bulgular bir arada değerlendirildiğinde, mevcut bilimsel kanıtların, ticarileştirilmiş Bt mısır çeşitlerinde kullanılan Cry proteinlerinin bal arıları için doğrudan toksik bir risk oluşturmadığı söylenebilir.

Mısır Kaynaklı Ürünlerin Arı Beslemesinde Kullanımı: Yüksek Fruktozlu Mısır Şurubu

Mısırın arıcılıkla ilişkisi yalnızca tarla düzeyinde polen kaynağı olmasıyla sınırlı değildir. Mısır nişastasından endüstriyel olarak üretilen yüksek fruktozlu mısır şurubu özellikle Kuzey Amerika'da ticari arıcılıkta yaygın bir tamamlayıcı besleme kaynağı olarak kullanılmaktadır. Bal hasadı sonrası kolonilerin karbonhidrat ihtiyacını karşılamak, nektar akışının kesildiği dönemlerde besleme yapmak ya da yavru üretimini teşvik etmek amacıyla tercih edilen şurup, maliyet avantajı nedeniyle sakaroz şurubuna alternatif olarak yaygın biçimde kullanılmaktadır.

Ancak şurubun ısıya ve depolama koşullarına duyarlı bir bileşik olan hidroksimetilfurfural açısından risk taşıdığı bilinmektedir. Le Blanc ve ark. (2009), sıcaklık arttıkça ve depolama süresi uzadıkça HMF düzeyinin belirgin biçimde yükseldiğini, yüksek düzeylerdeki HMF'nin bal arılarında bağırsak ülserasyonu ve dizanteri benzeri belirtilere yol açarak toksik etki gösterebildiğini bildirmiştir.

Arıcıların YFMŞ kullanırken ürünü aşırı ısıtmaktan kaçınması, uzun süreli ve sıcak ortamlarda depolamaması, mümkün olduğunda düşük HMF içerikli şuruplar veya sakaroz temelli alternatifleri tercih etmesi dikkat edilmesi gereken hususlardandır.

SONUÇ

Bu derleme, mısırın (*Zea mays* L.) arıcılık açısından önemini ve arı merası olarak kullanılma potansiyelini ele almıştır. Elde edilen bulgular, mısırın rüzgarla tozlaşan bir bitki olmasına karşın, üretkenliği son derece yüksek püskül yapısı sayesinde bal arıları için önemli bir dönemsel polen kaynağıdır. Ancak bu polenin protein ve amino asit içeriği bakımından sınırlı besinsel değere sahiptir. Modern mısır tarımının ayrılmaz bir parçası hâline gelen neonikotinoid tohum ilaçlamaları, bitkinin sunduğu bu sınırlı faydayı gölgeleyebilecek düzeyde ciddi bir arı sağlığı riski oluşturmaktadır. Transgenik (Bt) çeşitlerde kullanılan Cry proteinlerinin arılara doğrudan bir tehdit oluşturmadığı tespit edilmiştir. Mısır üretim alanlarının arı merası çeşitliliğini azaltarak kolonilerde mevsimsel ziyafet-kıtlık dinamiğine yol açtığı, ancak bu olumsuz etkinin doğal/yarı doğal bitki örtüsü ile desteklenen alanlarda büyük ölçüde telafi edilebileceği görülmektedir. Dolayısıyla mısırın arı merası olarak gerçek potansiyeli, bitkinin kendi başına taşıdığı özelliklerden çok, içinde yer aldığı tarımsal üretimin bütünsel yapısına, doğal ya da yarı doğal bitkilerin varlığına ve uygulanan bitki koruma ürünlerine bağlıdır.

Sonuç olarak, mısır arı merası kurulumunda göz ardı edilmemesi gereken, dönemsel ve tamamlayıcı bir polen kaynağı olarak değerlendirilmeli, sürdürülebilir bir katkı sağlaması için tarımsal alanların floral

çeşitlilik açısından zenginleştirilmesi, tohum ilaçlaması kaynaklı akut ve kronik pestisit maruziyetinin azaltılması ve arı beslemesinde kullanılan mısır kaynaklı yardımcı ürünlerin güvenli koşullarda saklanması gibi tamamlayıcı önlemlerle bir arada ele alınmalıdır. Türkiye özelinde bu potansiyelin doğrulanabilmesi için arı bitki ilişkisini inceleyen çalışmalara, tarımsal ürün kovan karşılaştırmalarına, arıları davranışlarını inceleyen vb. çalışmalara ihtiyaç duyulmaktadır.

Özet

Bu çalışmada, sulu tarım, endüstriyel üretim ve yem bitkileri deseni kapsamında söz konusu ürünlerin 2020-2024 dönemindeki ekiliş alanı, üretim miktarı ve verim değişimlerinin değerlendirilmesi amaçlanmıştır. Bu kapsamda; Sivas ilinde şeker pancarı, patates, ayçiçeği, yonca, silajlık mısır ve kuru fasulye; üretim miktarı, verim düzeyi ve ürün desenine sağladıkları katkı bakımından öne çıkan bitkisel ürünler arasında yer almaktadır. Şeker pancarında ekiliş alanı 2020 yılında 170.727 dekar iken 2024 yılında 181.976 dekara, üretim miktarı ise 975.782 tondan 1.035.924 tona yükselmiş ve ürün dönem boyunca genel olarak istikrarlı bir yapı göstermiştir. Patates üretiminde daha belirgin bir gelişme gerçekleşmiş ve 2020-2024 yıllarında ekiliş alanı 65.873 dekardan 140.108 dekara, üretim miktarı 192.630 tondan 560.398 tona çıkmış ve Sivas'ın Türkiye patates üretimindeki payı %3,70'ten %8,12'ye ulaşmıştır. Ayçiçeğinde 2020 yılında 2.394 dekar olan ekiliş alanı 2022 yılında 83.337 dekara kadar yükselmiş, üretim miktarı 2023 yılında 22.452 tonla dönem içerisindeki en yüksek seviyeye ulaşmış, 2024 yılında ise ekiliş alanı ve üretimde kısmi bir gerileme görülmüştür. Yem bitkileri içerisinde yonca ekiliş alanı ve üretim miktarında azalma meydana gelmesine rağmen verim 2021 sonrasında yeniden artarak 2024 yılında 786 kg/da düzeyine ulaşmıştır. Silajlık mısırda 2020 yılında 20.484 dekar olan ekiliş alanı 2024 yılında 24.893 dekara, üretim miktarı 94.473 tondan 122.973 tona yükselmiş; aynı yıl 4.940 kg/da ile dönemin en yüksek verimi elde edilmiştir. Silajlık mısırın özellikle sulama imkânlarının bulunduğu arazilerde yetiştirildiği, yoncada ise sulama ve gübreleme yönetiminin verimliliği desteklediği görülmektedir. Kuru fasulye üretimi yıllar arasında dalgalı bir yapı göstermiş; ekiliş alanı 2022 yılında 6.770 dekar ve üretim 946 ton ile en yüksek seviyesine ulaşmış, 2024 yılında ise sırasıyla 4.910 dekar ve 699 ton olarak gerçekleşmiştir. Sonuç olarak, incelenen ürünler Sivas'ta üretim deseninin çeşitlenmesi ve birim alandan farklı düzeylerde üretim sağlanması bakımından önemli bir potansiyel ortaya koymaktadır. Ürünler arasında ekiliş alanı, üretim ve verim bakımından farklı eğilimlerin bulunması, üretim planlamasının ürün bazında ve bölgesel koşullar dikkate alınarak yapılmasının önemini göstermektedir.

Anahtar kelimeler: Şeker pancarı, patates, ayçiçeği, yem bitkileri, silajlık mısır, ürün

Abstract

This study aimed to evaluate the changes in cultivated area, production quantity, and yield of the relevant crops during the 2020-2024 period within the scope of irrigated agriculture, industrial production, and forage crop patterns. In this context, sugar beet, potato, sunflower, alfalfa, silage maize, and dry bean are among the prominent crops in Sivas Province in terms of production quantity, yield level, and their contribution to the cropping pattern. In sugar beet, the cultivated area increased from 170,727 decares

in 2020 to 181,976 decares in 2024, while production increased from 975,782 tons to 1,035,924 tons, and the crop generally showed a stable structure throughout the period. A more pronounced development occurred in potato production, and between 2020 and 2024 the cultivated area increased from 65,873 decares to 140,108 decares, while production increased from 192,630 tons to 560,398 tons, and the share of Sivas in Türkiye's potato production reached 8.12% from 3.70%. In sunflower, the cultivated area, which was 2,394 decares in 2020, increased to 83,337 decares in 2022, while production reached the highest level of the period at 22,452 tons in 2023, and a partial decline in cultivated area and production was observed in 2024. Among forage crops, although a decrease occurred in alfalfa cultivation area and production quantity, yield increased again after 2021 and reached 786 kg/da in 2024. In silage maize, the cultivated area increased from 20,484 decares in 2020 to 24,893 decares in 2024, while production increased from 94,473 tons to 122,973 tons; in the same year, the highest yield of the period was obtained at 4,940 kg/da. It is observed that silage maize is grown especially in areas where irrigation opportunities are available, while irrigation and fertilization management support productivity in alfalfa. Dry bean production showed a fluctuating pattern among years; the cultivated area reached its highest level at 6,770 decares and production at 946 tons in 2022, while in 2024 these values were 4,910 decares and 699 tons, respectively. In conclusion, the crops examined reveal important potential in terms of diversification of the cropping pattern in Sivas and achieving different levels of production per unit area. The presence of different trends among crops in terms of cultivated area, production, and yield demonstrates the importance of carrying out production planning on a crop-specific basis and by taking regional conditions into consideration.
Keywords: Sugar beet, potato, sunflower, forage crops, silage maize, cropping pattern

GİRİŞ

Tarımsal üretim sistemlerinin sürdürülebilirliği, üretim kaynaklarının etkin kullanılması ve farklı çevresel ve ekonomik koşullara uyum sağlayabilecek ürün desenlerinin oluşturulmasıyla yakından ilişkilidir. Tek ürüne dayalı üretim sistemleri çevresel ve ekonomik değişkenlik karşısında daha kırılgan bir yapı gösterebilirken, ürün deseninin çeşitlendirilmesi üretim sistemlerinin dayanıklılığının artırılmasına katkı sağlayabilmektedir. Farklı ürünlerin üretim sistemine dahil edilmesi aynı zamanda toprak özellikleri, besin maddesi kullanımı ve tarımsal ekosistem hizmetleri açısından da çeşitli avantajlar sağlayabilmektedir (Lin, 2011; Tamburini vd., 2020).

Ürün deseninin belirlenmesinde su kaynaklarının varlığı ve sulama olanakları temel faktörlerden biridir. Özellikle bitkinin gelişme dönemindeki su gereksiniminin doğal yağışlarla karşılanamadığı koşullarda sulama, üretim miktarı ve birim alan veriminin sürdürülebilmesi açısından önem kazanmaktadır. Bununla birlikte tarımsal su verimliliği yalnızca uygulanan sulama miktarına bağlı olmayıp ürün seçimi, toprak ve bitki besleme yönetimi ile diğer yetiştirme uygulamalarının birlikte değerlendirilmesini gerektirmektedir (Molden vd., 2010). Bu nedenle sulu tarım koşullarında ürün planlaması yapılırken yalnızca yüksek üretim potansiyeline değil, suyun etkin kullanımı ve ürünlerin bölgesel koşullara uyumuna da dikkat edilmesi gerekmektedir.

Tarımsal üretim deseninin çeşitlenmesinde gıda üretiminin yanı sıra sanayiye hammadde sağlayan ürünler de önemli bir yere sahiptir. Şeker pancarı dünya şeker üretiminin önemli kaynaklarından biri olup gıda ve sanayi sektörleriyle doğrudan ilişkili bir endüstri bitkisidir (Tayyab vd., 2023). Patates ise geniş adaptasyon yeteneği, yüksek üretim potansiyeli ve hem doğrudan tüketim hem de işlenmiş gıda sektöründeki kullanımı nedeniyle küresel gıda sisteminin önemli ürünleri arasında yer almaktadır (Devaux vd., 2021). Yağlı tohumlar içerisinde ayçiçeği de bitkisel yağ üretimi ve elde edilen yan ürünlerin yem sektöründeki kullanımı bakımından küresel ölçekte önemli bir tarımsal üründür (Pilorgé, 2020). Bu ürünlerin farklı kullanım alanlarına sahip olması, tarımsal üretim ile gıda ve sanayi sektörleri arasındaki bağlantıyı güçlendirmektedir. Üretim deseninin bir diğer önemli bileşenini yem bitkileri oluşturmaktadır. Bitkisel ve hayvansal üretimin birlikte yürütüldüğü bölgelerde kaliteli kaba yem üretiminin artırılması, hayvancılığın sürdürülebilirliği açısından önem taşımaktadır. Yonca ve silajlık mısır, yüksek yem değerleri ve farklı kullanım özellikleri nedeniyle yaygın olarak yetiştirilen başlıca yem bitkileri arasında yer almaktadır. Türkiye'de de yonca ve silajlık mısır, yem bitkileri üretiminde öne çıkan ürünler arasında bulunmakta ve kaliteli kaba yem ihtiyacının karşılanmasına katkı sağlamaktadır (Tan ve Yolcu, 2021). Bitkisel ve hayvansal üretimin bütünleşik biçimde ele alınması, tarımsal kaynakların daha etkin değerlendirilmesine ve üretim sisteminin farklı bileşenleri arasında tamamlayıcılık oluşturulmasına olanak sağlamaktadır (Lemaire vd., 2014; Martin vd., 2016). Baklagiller

de insan beslenmesine sağladıkları katkının yanında tarımsal üretim sistemleri açısından önem taşımaktadır. Kuru fasulye, yüksek protein, lif ve mineral içeriği nedeniyle dünya genelinde önemli bir besin kaynağı olarak değerlendirilirken, baklagil özelliği ve kısa yetişme dönemi ürün rotasyonlarının çeşitlendirilmesine katkı sağlayabilmektedir (Uebersax vd., 2023). Türkiye'de kuru fasulye üretimi; tüketim, üretim ve pazarlama yapısı bakımından yemeklik tane baklagiller içerisinde önemli bir konuma sahiptir (Küzeci vd., 2019).

Sivas'ta karasal iklim koşulları, geniş tarım alanları, bitkisel üretim ile hayvancılığın birlikte yürütülmesi ve farklı ürün gruplarının yetiştirilebilmesi ilin tarımsal ürün desenini şekillendirmektedir. Sivas koşullarında yapılan çalışmalar, şeker pancarı ve ayçiçeği gibi ürünlerde su kullanımının üretim sistemi açısından değerlendirilmesi gerektiğini ortaya koyarken, farklı yonca çeşitlerinin il ekolojik koşullarındaki verim ve kalite özellikleri de araştırılmıştır (Polat Bulut ve Topal Canbaz, 2022; Karaköy ve Saraç, 2018).

Bu çalışma kapsamında ele alınan 2020-2024 verilerinde de şeker pancarı, patates, ayçiçeği, yonca, silajlık mısır ve kuru fasulyenin ekiliş alanı, üretim miktarı ve verim bakımından birbirinden farklı gelişim eğilimleri gösterdiği görülmektedir. Bu çalışmada söz konusu ürünlerin 2020-2024 dönemindeki değişimlerinin değerlendirilmesi ve Sivas ilindeki üretim deseninin ürün bazında ortaya konulması amaçlanmıştır.

ENDÜSTRİ BİTKİLERİ

Sivas'ta tarıma dayalı sanayinin varlığı ve entegre üretim yapısı, endüstri bitkilerinin il geneline yayılan üretim deseni içerisindeki stratejik önemini her geçen gün artırmaktadır. Bölgenin iklim koşulları ve toprak yapısı doğrultusunda şekillenen bu grup içerisinde, özellikle şeker pancarı, patates ve ayçiçeği öne çıkan ürünler olarak dikkat çekmektedir. Bu ürünler, ekim nöbeti sistemindeki rolleri, su ve yetiştiricilik ihtiyaçları bakımından farklı üretim eğilimleri sergilemekle birlikte; gerek imalat sanayisine girdi sağlayan hammadde nitelikleriyle gerekse kırsal kalkınmaya sundukları yüksek katma değerle hem bölgesel ekonomi hem de tarımsal sürdürülebilirlik için oldukça önemli bir yere sahiptir.

Şeker Pancarı (*Beta vulgaris* L.) Üretimi

Şeker pancarı, dünya şeker üretiminde şeker kamışıyla birlikte temel hammadde kaynaklarından biri olup özellikle ılıman iklim kuşağında önemli bir endüstri bitkisidir. Dünya şeker gereksiniminin yaklaşık dörtte birinin şeker pancarından karşılanması, ürünün gıda sanayisi açısından önemini ortaya koymaktadır (Tayyab vd., 2023). Türkiye'de de şeker pancarı üretimi tarıma dayalı sanayiyle doğrudan ilişkili olup şeker fabrikaları, üretim politikaları ve kırsal ekonomi bakımından önemli bir yapıya sahiptir (Demirdöğen, 2022). Sivas koşullarında şeker pancarının su ayak izinin araştırılmış olması da bu ürünün su kullanımı ve bölgesel üretim yapısı açısından önem taşıdığını göstermektedir (Polat Bulut ve Topal Canbaz, 2022). Bu özellikler, şeker pancarının Sivas'taki üretim seyrinin ekiliş alanı, üretim miktarı ve verim göstergeleri bakımından birlikte değerlendirilmesini önemli hâle getirmektedir.

Bu kapsamda 2020-2024 dönemi incelendiğinde, şeker pancarında ekiliş alanı ve üretim miktarı 2021 yılında belirgin biçimde gerilemiş, izleyen yıllarda yeniden artış göstermiştir. Üretim 2023 yılında bir milyon tonun üzerine çıkmış ve 2024 yılında 1.035.924 tona ulaşmıştır. Sivas'ın Türkiye toplam şeker pancarı ekiliş alanındaki payının dönem boyunca yaklaşık %5 düzeyinde seyretmesi de ürünün il tarımı içerisindeki sürekliliğine işaret etmektedir (Çizelge 1).

2021 yılında görülen düşük üretim ve verimde kuraklık ve olumsuz iklim koşulları etkili olmuş; yağışların mevsim normallerinin altında kalması bitki gelişimini olumsuz etkilemiştir. Sonraki yıllarda üretim yeniden yükselmiş ve Sivas'ta şeker pancarı verimi 2023 yılında 6.149 kg/da ile dönem içerisindeki en yüksek seviyesine ulaşmıştır. Bununla birlikte çizelgedeki değerler karşılaştırıldığında Sivas'ta şeker pancarı veriminin 2020-2024 yıllarının tamamında Türkiye ortalamasının altında kaldığı görülmektedir.

Çizelge 1. Sivas ili şeker pancarı üretim verilerinin yıllara göre değişimi

Yıl	Ekiliş alanı (da)	Türkiye ekiliş alanındaki payı (%)	Üretim (ton)	Türkiye üretimindeki payı (%)	Türkiye verimi (kg/da)	Sivas verimi (kg/da)
2020	170.727	5,05	975.782	4,24	6.810	5.730
2021	150.174	4,92	798.232	4,49	5.818	5.336
2022	151.393	5,09	841.741	4,37	6.472	5.599

2023	167.305	4,60	1.026.004	4,06	6.936	6.149
2024	181.976	5,53	1.035.924	4,62	6.811	5.700

Kaynak: TÜİK, Bitkisel Üretim İstatistikleri (2020-2024)

Patates (*Solanum tuberosum* L.) Üretimi

Patates, yüksek verim potansiyeli, besin değeri ve farklı iklim bölgelerinde yetiştirilebilmesi nedeniyle dünya gıda sisteminin temel ürünlerinden biridir. Gıda güvenliğine katkısının yanı sıra taze tüketim, işlenmiş gıda ve nişasta gibi farklı kullanım alanlarına sahip olması ürünün ekonomik önemini artırmaktadır (Devaux vd., 2021). Türkiye'de de patates önemli bir bitkisel ürün olup, dış ticaret ve tarımsal destek politikaları açısından ayrı bir üretim yapısına sahiptir (Kadakoğlu ve Karlı, 2021). Bu genel önem içerisinde Sivas'ta son yıllarda görülen üretim gelişimi, patatesin il ürün deseni içerisindeki konumunun ayrıca değerlendirilmesini gerekli kılmaktadır.

Nitekim 2020-2024 döneminde patates, incelenen ürünler içerisinde ekiliş alanı ve üretim miktarı bakımından en belirgin gelişmelerden birini göstermiştir. Sivas'taki ekiliş alanı beş yıllık dönemde iki katın üzerine çıkarken üretim miktarı da 192.630 tondan 560.398 tona ulaşmıştır. Bu gelişmeyle birlikte Sivas'ın Türkiye patates üretimindeki payı %3,70'ten %8,12'ye yükselmiştir (Çizelge 2). Üretimdeki gelişim yalnızca alan genişlemesiyle sınırlı kalmamış, özellikle 2022 ve 2023 yıllarında verimde de belirgin artış meydana gelmiştir. Sivas'ta patates verimi 2023 yılında 4.567 kg/da ile dönem içerisindeki en yüksek seviyeye ulaşmış, 2024 yılında ise 4.000 kg/da'a gerilemiştir. 2022-2023 dönemindeki gelişimde ekiliş alanındaki genişleme ile üretim tekniklerindeki iyileşmeler birlikte etkili olurken, 2024 yılındaki hızlı alan artışı patates verimi üzerinde kısa vadeli bir baskı oluşturmuştur.

Çizelge 2. Sivas ili patates üretim verilerinin yıllara göre değişimi

Yıl	Ekiliş alanı (da)	Türkiye ekiliş alanındaki payı (%)	Üretim (ton)	Türkiye üretimindeki payı (%)	Türkiye verimi (kg/da)	Sivas verimi (kg/da)
2020	65.873	4,45	192.630	3,70	3.514	2.924
2021	71.180	5,12	194.742	3,82	3.671	2.736
2022	86.490	6,21	334.435	6,43	3.736	3.867
2023	89.862	5,95	410.377	7,20	3.777	4.567
2024	140.108	7,16	560.398	8,12	3.524	4.000

Kaynak: TÜİK, Bitkisel Üretim İstatistikleri (2020-2024)

Ayçiçeği (*Helianthus annuus* L.) Üretimi

Ayçiçeği, dünya bitkisel yağ sektörünün temel yağlı tohum ürünlerinden biri olup yağ üretiminin yanı sıra işleme sonucunda elde edilen küspenin hayvan beslemede kullanılabilmesi nedeniyle çok yönlü bir tarımsal üründür (Pilorgé, 2020). Türkiye'de ayçiçeği bitkisel yağ üretimi açısından stratejik öneme sahip ürünler arasında bulunmakta ve üretim alanı, verimlilik ve tarım politikaları bakımından önemini korumaktadır (Angın vd., 2025). Sivas'ta yağlık ayçiçeği yetiştiriciliğinin üretici düzeyinde doğrudan araştırmalara konu olması da ürünün bölgede giderek önem kazandığını göstermektedir (Yemen ve Belgüzar, 2024). Bu durum, ayçiçeğinin Sivas ürün desenindeki konumunun son yıllardaki ekiliş alanı, üretim ve verim değişimleri üzerinden değerlendirilmesini önemli hâle getirmektedir.

Bu doğrultuda 2020-2024 dönemindeki üretim seyri incelendiğinde ayçiçeğinde özellikle 2021-2023 döneminde hızlı bir genişleme meydana gelmiştir. Ekiliş alanı 2020 yılında 2.394 dekar düzeyindeyken 2022 yılında 83.337 dekara ulaşmış, üretim miktarı ise 2023 yılında 22.452 tonla dönem içerisindeki en yüksek seviyesine çıkmıştır. Buna paralel olarak Sivas'ın Türkiye ayçiçeği üretimindeki payı 2023 yılında %1,02'ye kadar yükselmiştir. 2024 yılında ise hem alan hem de üretim miktarında kısmi bir gerileme görülmüştür (Çizelge 3). Ekiliş alanındaki dalgalanmaya karşılık yağlık ayçiçeğinde verim dönem boyunca yükselmiş ve 2024 yılında 293 kg/da'a ulaşmıştır. Çerezlik ayçiçeğinde ise 2023 yılında 232 kg/da ile en yüksek değer elde edilmiş, 2024 yılında 198 kg/da'a gerilemiştir. Bu yapı, ayçiçeğinin Sivas'taki üretim desenine kısa sürede daha belirgin biçimde dahil olduğunu, ancak son yıldaki alan ve üretim gerilemesinin üretim eğiliminin sürekliliği bakımından izlenmesi gerektiğini göstermektedir.

Çizelge 3. Sivas ili ayçiçeği üretim verilerinin yıllara göre değişimi

Yıl	Ekiliş alanı (da)	Türkiye ekiliş alanındaki payı (%)	Üretim (ton)	Türkiye üretimindeki payı (%)	Türkiye verimi (kg/da)	Yağlık verim (kg/da)	Çerezlik verim (kg/da)
2020	2.394	0,03	467	0,02	284	195	122
2021	14.000	0,16	2.796	0,12	268	200	129
2022	83.337	0,85	20.272	0,79	260	243	201
2023	81.516	0,86	22.452	1,02	231	275	232
2024	63.893	0,66	18.715	0,85	225	293	198

Kaynak: TÜİK, Bitkisel Üretim İstatistikleri (2020-2024)

YEM BİTKİLERİ

Sivas'ta hayvancılığın yaygın olması, yem bitkilerinin üretim deseni içerisindeki önemini artırmaktadır. Bu çalışmada yem bitkileri içerisinde yonca ve silajlık mısır ele alınmıştır. İki ürün farklı üretim eğilimlerine sahip olmakla birlikte kaliteli kaba yem sağlanması bakımından hayvansal üretimle doğrudan ilişkilidir.

Yonca (*Medicago sativa* L.) Üretimi

Yonca, yüksek kaliteli kaba yem üretimi, çok yıllık yapısı ve baklagil özelliği nedeniyle dünya genelinde önemli yem bitkilerinden biridir. Tarımsal üretim sistemlerinde yem kaynağı oluşturmasının yanı sıra ekim nöbeti, azot fiksasyonu ve tarımsal ekosistem üzerindeki olumlu etkileri bakımından da değerlendirilmektedir (del Portillo vd., 2022). Türkiye'de yonca, silajlık mısır, yulaf, fiğ ve korungayla birlikte temel yem bitkileri arasında yer almakta ve kaliteli kaba yem üretimi açısından önem taşımaktadır (Tan ve Yolcu, 2021). Sivas ekolojik koşullarında farklı yonca çeşitleri üzerinde yürütülen çalışmalar da ürünün bölgede yüksek ve kaliteli ot üretimi potansiyeline sahip olduğunu göstermiştir (Karaköy ve Saraç, 2018). Yoncanın hayvansal üretim açısından taşıdığı bu önem, Sivas'taki ekiliş alanı, toplam üretim ve verim değişimlerinin birlikte değerlendirilmesini gerekli kılmaktadır.

Bu kapsamda 2020-2024 dönemi incelendiğinde, yonca ekiliş alanı 2022 yılına kadar sınırlı ölçüde artmış, daha sonra azalarak 2024 yılında 226.160 dekara gerilemiştir. Üretim miktarı da dönem sonunda 2020 düzeyinin altında kalmıştır. Buna karşılık Sivas'ın Türkiye toplam yonca ekiliş alanındaki payı %3,75'ten %4,03'e yükselmiş ve üretimdeki payı yaklaşık %1 düzeyinde korunmuştur (Çizelge 4). Verim 2021 yılında 674 kg/da'a gerilemiş, izleyen yıllarda düzenli biçimde artarak 2024 yılında 786 kg/da düzeyine ulaşmıştır. Tarımsal tekniklerin yanı sıra sulama ve gübreleme yönetimi verimliliği destekleyen uygulamalar arasında yer almaktadır. Buna karşılık su kısıtı bulunan alanlarda ekilişin azalması ve destekleme politikalarındaki değişiklikler üretim alanındaki daralmayı hızlandıran unsurlar arasında değerlendirilmiştir.

Çizelge 4. Sivas ili yonca üretim verilerinin yıllara göre değişimi

Yıl	Ekiliş alanı (da)	Türkiye ekiliş alanındaki payı (%)	Üretim (ton)	Türkiye üretimindeki payı (%)	Türkiye verimi (kg/da)	Sivas verimi (kg/da)
2020	248.850	3,75	197.630	1,02	2.923	794
2021	255.176	3,79	171.933	0,89	2.895	674
2022	258.699	4,02	186.501	0,98	2.974	721
2023	248.190	4,13	184.872	1,01	3.056	745
2024	226.160	4,03	177.726	1,02	3.105	786

Kaynak: TÜİK, Bitkisel Üretim İstatistikleri (2020-2024)

Silajlık Mısır (*Zea mays* L.) Üretimi

Silajlık mısır, yüksek biyokütle üretimi ve enerji değeri nedeniyle özellikle süt sığırı beslemesinde yaygın olarak kullanılan önemli kaba yem kaynaklarından biridir. Bütün bitki mısır silajı, süt sığırı rasyonlarında önemli bir yem bileşeni olup hasat zamanı ve silaj kalitesi hayvanların yem tüketimi ve üretim performansını etkileyebilmektedir (Ferraretto vd., 2018). Türkiye'de de silajlık mısır kaliteli kaba yem üretimi bakımından önem kazanmış ve hayvancılıkla ilişkili başlıca yem bitkilerinden biri hâline gelmiştir (Karadeniz, 2019; Tan ve Yolcu, 2021). Sivas'ta hayvancılığın yaygın olması ve silajlık mısırın özellikle sulama imkânı bulunan tarım arazilerinde yetiştirilmesi, ürünü ilin yem bitkileri üretimi

açısından önemli hâle getirmektedir. Bu özellikler, silajlık mısırın Sivas'taki üretim gelişiminin ekiliş alanı, toplam üretim ve birim alan verimi bakımından birlikte ele alınmasını önemli kılmaktadır.
2020-2024 dönemindeki üretim seyri değerlendirildiğinde silajlık mısırda ekiliş alanı ve üretim miktarı 2020'den 2022'ye kadar artmış ve her iki gösterge de 2022 yılında dönem içerisindeki en yüksek seviyesine ulaşmıştır. Sonraki iki yılda alan ve üretimde kısmi bir gerileme görülmesine rağmen 2024 değerleri 2020 düzeyinin üzerinde kalmıştır. Sivas'ın Türkiye üretimindeki payı da %0,35'ten %0,45'e yükselmiştir (Çizelge 5). Alan ve toplam üretimde 2022 sonrasında görülen gerilemenin aksine birim alan verimi yükselmeye devam etmiş ve 2024 yılında 4.940 kg/da ile beş yıllık dönemin en yüksek değerine ulaşmıştır. Sulama ve gübreleme yönetimi verim artışını destekleyen uygulamalar arasında yer almaktadır. Silajlık mısırın özellikle sulama imkânı bulunan alanlarda yetiştirilmesi nedeniyle su kısıtı bulunan bölgelerde üretim alanının genişlemesi sınırlanabilmektedir.

Çizelge 5. Sivas ili silajlık mısır üretim verilerinin yıllara göre değişimi

Yıl	Ekiliş alanı (da)	Türkiye ekiliş alanındaki payı (%)	Üretim (ton)	Türkiye üretimindeki payı (%)	Türkiye verimi (kg/da)	Sivas verimi (kg/da)
2020	20.484	0,39	94.473	0,35	5.226	4.612
2021	29.370	0,55	133.555	0,49	5.208	4.547
2022	31.458	0,59	149.251	0,52	5.444	4.744
2023	28.076	0,53	134.363	0,47	5.467	4.786
2024	24.893	0,49	122.973	0,45	5.424	4.940

YEMEKLİK DANE BAKLAGİLLER

Sivas, geniş tarım arazileri ve karasal iklim yapısıyla Türkiye'nin en önemli bitkisel üretim merkezlerinden biridir. Kentte yemeklik dane baklagil üretimi hem bölge ekonomisi hem de toprak yapısının korunması açısından stratejik bir öneme sahiptir

Kuru Fasulye (*Phaseolus vulgaris* L.) Üretimi

Kuru fasulye, doğrudan insan tüketiminde kullanılan en önemli baklagil türlerinden biri olup protein, diyet lifi ve mineral maddeler bakımından zengin bir besin kaynağıdır. Aynı zamanda baklagil özelliği, kısa yetişme süresi ve ekim nöbetlerinde kullanılabilmesi nedeniyle sürdürülebilir tarımsal üretim açısından da önem taşımaktadır (Uebersax vd., 2023). Türkiye'de kuru fasulye üretimi, tüketim ve pazarlama yapısı bakımından yemeklik tane baklagiller içerisinde önemli bir yere sahip olmakla birlikte üretim alanı ve miktarı yıllar içerisinde değişkenlik gösterebilmektedir (Küzeci vd., 2019). Sivas'ta ise üretim daha sınırlı düzeyde olmakla birlikte 2020-2024 döneminde ekiliş alanı, üretim ve verim değerlerindeki değişimler ürünün il üretim deseni içerisindeki gelişiminin izlenmesini gerekli kılmaktadır.
Bu doğrultuda 2020-2024 dönemi incelendiğinde, kuru fasulye üretimi dönem boyunca düzenli bir artış göstermemiştir. Ekiliş alanı 2022 yılında 6.770 dekarla en yüksek seviyesine ulaşırken, aynı yıl üretim miktarı da 946 tonla dönem içerisindeki en yüksek değeri göstermiştir. İzleyen yıllarda hem alan hem de üretim azalmış ve 2024 yılında sırasıyla 4.910 dekar ve 699 ton olarak gerçekleşmiştir (Çizelge 6). Verim bakımından ise farklı bir seyir ortaya çıkmış; 2021 yılında 98 kg/da'a gerileyen verim 2023 yılında 157 kg/da ile dönem içerisindeki en yüksek seviyesine ulaşmış ve 2024 yılında 142 kg/da olarak gerçekleşmiştir. Buna rağmen Sivas'taki verim değerleri incelenen yılların tamamında Türkiye ortalamasının altında kalmıştır. Üretim tekniklerindeki iyileşmeler, girdi kullanımındaki etkinlik ve uygun iklim koşulları verimdeki gelişmeyle ilişkilendirilen unsurlar arasında yer almaktadır.

Çizelge 6. Sivas ili kuru fasulye üretim verilerinin yıllara göre değişimi

Yıl	Ekiliş alanı (da)	Türkiye ekiliş alanındaki payı (%)	Üretim (ton)	Türkiye üretimindeki payı (%)	Türkiye verimi (kg/da)	Sivas verimi (kg/da)
2020	3.151	0,31	338	0,12	271	107
2021	4.068	0,38	399	0,13	283	98

2022	6.770	0,70	946	0,35	278	140
2023	5.408	0,61	849	0,35	271	157
2024	4.910	0,53	699	0,25	304	142

GENEL DEĞERLENDİRME VE SONUÇ

Sivas'ta 2020-2024 döneminde incelenen ürünler birlikte değerlendirildiğinde, farklı ürün gruplarının ekiliş alanı, üretim miktarı ve verim bakımından birbirinden farklı gelişim eğilimlerine sahip olduğu görülmektedir.

Endüstriyel üretimle ilişkili şeker pancarı dönem boyunca görece istikrarlı bir alan ve üretim yapısı gösterirken, patateste belirgin bir genişleme meydana gelmiştir. Patatesin hem ekiliş alanındaki hem de Türkiye toplam üretimindeki payındaki artış, ürünün Sivas bitkisel üretimindeki göreli ağırlığının dönem içerisinde yükseldiğini göstermektedir. Ayçiçeğinde ise daha hızlı ancak daha değişken bir gelişim görülmüştür. Ekiliş alanı ve üretim miktarının kısa süre içerisinde önemli ölçüde artmasının ardından 2024 yılında her iki göstergede de kısmi bir gerileme meydana gelmiştir. Buna karşılık yağlık ayçiçeğinde verimin dönem boyunca yükselmesi, üretim alanı ile birim alan veriminin her zaman aynı yönde değişmediğini ortaya koymaktadır. Yem bitkilerinde de benzer biçimde ürün bazında farklı eğilimler bulunmaktadır. Yonca ekiliş alanı ve toplam üretim miktarı dönem sonunda azalmasına rağmen verim 2021 yılından sonra yeniden yükselmiştir. Silajlık mısırda ekiliş alanı ve üretim 2022 yılında en yüksek düzeye ulaştıktan sonra kısmen gerilemiş, buna karşılık birim alan verimi yükselmeye devam ederek 2024 yılında dönem içerisindeki en yüksek değerine ulaşmıştır. Bu durum, yem bitkilerinde toplam üretimin yalnızca verim değişimiyle değil, üretim alanındaki gelişmelerle birlikte değerlendirilmesi gerektiğini göstermektedir. Kuru fasulyede ise ekiliş alanı ve üretim miktarında sürekli bir genişleme eğilimi ortaya çıkmamış; her iki gösterge 2022 yılında en yüksek düzeye ulaştıktan sonra gerilemiştir. Bununla birlikte verim değerlerinin 2022 sonrasında önceki iki yıla göre daha yüksek gerçekleşmesi, alan ve verim değişimlerinin farklı yönlerde gelişebildiğini göstermektedir.

Genel olarak Sivas'ta incelenen ürünler arasında şeker pancarı gibi görece istikrarlı bir üretim yapısına sahip ürünler ile patates ve ayçiçeği gibi daha belirgin alan değişimleri gösteren ürünler birlikte bulunmaktadır. Yonca, silajlık mısır ve kuru fasulyede ise üretim alanı, toplam üretim ve verim göstergelerinin farklı yönlerde geliştiği görülmektedir. Bu nedenle Sivas'taki üretim deseninin planlanmasında ekiliş alanı, birim alan verimi, yıllar arasındaki üretim değişkenliği ve ürünlerin su gereksinimlerinin birlikte değerlendirilmesi önem taşımaktadır.

MULTI-OBJECTIVE OPTIMIZATION OF PHOTOVOLTAIC SYSTEM ORIENTATION CONSIDERING ADJUSTMENT EFFORT INDEX

Oğuzkağan ALIÇ

Asst. Prof. Dr., Eskişehir Technical University, Faculty of Engineering, Department of Electrical and Electronics Engineering, Eskişehir-Türkiye
ORCID: 0000-0001-8611-7987

Abstract
This study presents a multi-objective optimization framework for determining monthly photovoltaic (PV) panel orientations while considering both solar irradiation capture and the practical effort required for orientation adjustments. Two strategies are investigated: joint optimization of monthly tilt and azimuth angles and tilt-only optimization with the azimuth fixed at 0° (south-facing). Annual plane-of-array (POA) irradiation is maximized, while orientation adjustment effort is minimized through a proposed Adjustment Effort Index (AEI), which accounts for both the number of interventions and cumulative angular movements. The analysis is performed using measured global, diffuse, and beam horizontal irradiance data obtained from the Renewable Energy Research Home at Eskişehir Technical University, Türkiye. A multi-objective genetic algorithm is employed to obtain the Pareto-optimal orientation schedules, and the two strategies are evaluated using maximum-irradiation solutions, compromise solutions, and equal-AEI comparisons. The joint tilt-azimuth strategy achieved a maximum annual POA irradiation of 1841.82 kWh/m², compared with 1796.97 kWh/m² for tilt-only optimization, corresponding to a 2.50% improvement. For the selected compromise solutions, joint optimization increased annual POA irradiation from 1790.97 to 1825.01 kWh/m² (1.90%), while both strategies required six orientation interventions. Moreover, cumulative tilt movement decreased from 68° to 29° by distributing the orientation changes between tilt and azimuth. The results demonstrate that incorporating azimuth flexibility can improve solar irradiation capture without necessarily increasing the overall adjustment effort, providing a practical basis for periodically adjustable PV systems.
Keywords: Photovoltaic systems, tilt angle, azimuth angle, multi-objective optimization, solar irradiance, adjustment effort.

Introduction

Background

Photovoltaic (PV) systems have become an increasingly important component of sustainable electricity generation. In addition to module characteristics and environmental conditions, PV array orientation directly affects the solar irradiance received by the module surface and consequently its energy-generation potential. The orientation is primarily determined by the tilt and azimuth angles, while the optimal values of these angles vary throughout the year due to changes in solar geometry. Therefore, appropriately selecting PV orientation can improve solar energy utilization without increasing the installed PV capacity.

Fixed-orientation PV systems are simple and require no operational intervention; however, a single annual orientation cannot continuously provide favourable irradiation conditions throughout the year. Periodic adjustment of the panel orientation, such as monthly or seasonal reorientation, provides an intermediate alternative between fixed installations and continuously operating solar tracking systems. Nevertheless, maximizing irradiation through frequent orientation changes may require considerable operational or mechanical effort, particularly when both tilt and azimuth angles are adjustable.

Most PV orientation optimization studies primarily aim to maximize incident solar irradiation or energy production. However, the practical effort associated with transitioning between successive orientations is generally not explicitly considered as an optimization objective. The number of adjustments alone cannot fully represent this effort, since schedules having the same number of interventions may involve considerably different angular displacements. Therefore, PV orientation optimization should consider not only the attainable irradiation but also the frequency and magnitude of the required orientation changes.

In this study, a multi-objective framework is proposed to simultaneously maximize annual plane-of-array (POA) irradiation and minimize orientation adjustment effort. An Adjustment Effort Index (AEI)

is formulated by considering the number of orientation interventions together with cumulative tilt and azimuth movements. Two strategies are investigated: joint monthly optimization of tilt and azimuth angles and monthly tilt-only optimization with the azimuth fixed at 0° (south-facing). Their Pareto fronts, compromise solutions, and performance under equal AEI constraints are compared to quantify the additional benefit provided by azimuth flexibility.

The analysis is conducted using measured global horizontal irradiance (GHI), diffuse horizontal irradiance (DHI), and beam horizontal irradiance (BHI) data obtained from the Renewable Energy Research Home (RERH) at the Iki Eylul Campus of Eskişehir Technical University, Eskişehir, Türkiye. The main contribution of the study is therefore a practical multi-objective PV orientation methodology that explicitly incorporates both irradiation gain and orientation-adjustment effort, enabling the additional value of azimuth optimization to be evaluated under equivalent operational-effort conditions.

Literature Review

The orientation of a PV panel strongly influences the amount of solar irradiation received by its surface. Early studies therefore focused on determining optimum tilt and orientation angles for different locations and operating periods. Ibrahim investigated south-facing solar collectors in Cyprus and showed that near-optimal solar energy collection could be achieved by adjusting the tilt angle four times per year (Ibrahim, 1995). Bari developed a computational procedure for determining both the optimum slope and orientation of solar collectors for different periods of utilization while considering direct and diffuse solar radiation (Bari, 2000). Similarly, Yakup and Malik optimized both tilt and surface azimuth angles for Brunei Darussalam and reported that monthly tilt adjustment could provide annual solar irradiation close to that obtained through daily optimum adjustment (Yakup & Malik, 2001).

Location-specific studies have also demonstrated that optimum PV orientation cannot be determined accurately using latitude alone. Kacira et al. determined optimum PV tilt angles for Şanlıurfa, Türkiye, and reported monthly values ranging from 13° in June to 61° in December. They also showed that monthly optimum tilt angles increased the received solar radiation compared with seasonal and latitude-based configurations (Kacira et al., 2004). Tang and Wu emphasized that the optimum tilt angle depends on local climatic conditions, geographic latitude, and the period of utilization (Tang & Wu, 2004). For Türkiye, Bakirci used measured solar radiation data from eight provinces and demonstrated substantial seasonal variation in optimum tilt angles (Bakirci, 2012). These findings are also consistent with the comprehensive review by Yadav and Chandel, who concluded that optimum tilt is both site- and time-dependent and should therefore be determined using appropriate radiation models and optimization techniques (Yadav & Chandel, 2013).

The use of tracking systems provides an alternative means of increasing irradiation capture by continuously or periodically modifying panel orientation. Koussa et al. compared fixed PV configurations with several single- and two-axis tracking systems using hourly measured data under different sky conditions and demonstrated that tracking can significantly increase energy yield, although the achieved gains depend strongly on environmental conditions (Koussa et al., 2011). A broader review of tilt, azimuth, and tracking strategies was presented by Hafez et al., confirming that both tilt and azimuth optimization have been extensively studied for different solar-energy applications (Hafez et al., 2017). However, tracking systems generally involve additional mechanical components, operational energy requirements, and maintenance costs. For this reason, periodically adjustable PV structures can provide a practical compromise between completely fixed systems and continuously operating tracking systems.

The trade-off between energy gain and adjustment frequency has therefore received increasing attention. Despotovic and Nedic compared yearly, biannual, seasonal, monthly, fortnightly, and daily optimum tilt schedules and showed that increasing the frequency of adjustment does not necessarily result in proportional increases in collected energy. They also reported relatively small differences among daily, fortnightly, and monthly optimum configurations and emphasized the importance of cost-benefit considerations (Despotovic & Nedic, 2015). More recently, Prunier et al. proposed a bi-layer optimization approach that determines both optimum tilt angles and the dates of panel reorientation. Their results indicated that two reorientations per year could improve annual energy production by up to 4.8%, whereas further increases in the number of adjustments provided progressively smaller additional gains (Prunier et al., 2023).

Recent studies have also adopted more detailed radiation datasets and data-driven optimization approaches. Inan et al. determined annual, seasonal, and monthly optimum tilt angles for seven cities in Türkiye using PVGIS data and reported energy gains of up to 4.20% and 5.05% for seasonal and monthly adjustment, respectively (Inan et al., 2024). Lu and Qin used long-term hourly solar radiation data to determine location-specific optimum PV tilt angles across China and showed that the optimum angle is sensitive to both regional climate variability and the time period considered in the optimization (Lu & Qin, 2024).

Despite these developments, the reviewed studies predominantly focus on maximizing solar irradiation or energy production, while the practical effort associated with panel reorientation is generally represented indirectly through predefined adjustment frequencies. Although several studies acknowledge the practical and economic implications of reorientation (Yakup & Malik, 2001; Despotovic & Nedic, 2015) and recent work has optimized the timing of tilt adjustments (Prunier et al., 2023), the reviewed literature does not explicitly formulate adjustment effort as a competing optimization objective that simultaneously considers both the number of interventions and cumulative angular displacement. Furthermore, a direct comparison between joint tilt-azimuth optimization and tilt-only optimization under equivalent adjustment-effort conditions has not been addressed within the reviewed studies. Therefore, the present study introduces an AEI and formulates PV orientation as a multi-objective optimization problem in which annual plane-of-array irradiation is maximized while orientation adjustment effort is minimized.

Mathematical Formulation

Problem Definition

The PV orientation problem is formulated as a bi-objective optimization problem in which the annual POA irradiation is maximized while the practical effort associated with panel orientation is minimized. Two monthly orientation strategies are considered. In the first strategy, monthly tilt and azimuth angles are jointly optimized, with separate decision variables assigned to each month. In the second strategy, only the monthly tilt angles are optimized while the azimuth angle is maintained at 0°, corresponding to a south-facing orientation.

For month m, β_m and γ_m denote the PV tilt and azimuth angles, respectively. For the joint tilt-azimuth optimization case, the decision vector is

$$\mathbf{x}_{TA} = [\beta_1, \dots, \beta_{12}, \gamma_1, \dots, \gamma_{12}]. \quad (1)$$

For the tilt-only optimization case, the decision vector is

$$\mathbf{x}_T = [\beta_1, \dots, \beta_{12}]. \quad (2)$$

while

$$\gamma_m = 0°, m = 1, \dots, 12. \quad (3)$$

The orientation variables are constrained by

$$0° \leq \beta_m \leq 90°, m = 1, \dots, 12. \quad (4)$$

and for the joint tilt-azimuth case,

$$-180° \leq \gamma_m \leq 180°, m = 1, \dots, 12. \quad (5)$$

A 1° angular resolution is adopted. The azimuth convention is defined such that $\gamma = 0°$ represents south, negative values represent eastward orientations, and positive values represent westward orientations.

Solar Geometry Model

The solar declination angle at hourly time step t is calculated as (Barbón et al., 2022; Sunderan et al., 2011)

$$\delta(t) = 23.45° sin\left[\frac{360°(284+n(t))}{365}\right]. \quad (6)$$

where $n(t)$ denotes the day of the year.

The auxiliary parameter used in the equation-of-time calculations is

$$B(t) = \frac{360°}{365}[n(t) - 81]. \quad (7)$$

The equation of time is expressed as

$$EoT(t) = 9.87\sin(2B) - 7.53\cos(B) - 1.5\sin(B). \quad (8)$$

The time correction factor is

$$TC(t) = EoT(t) + 4(\lambda - \lambda_{std}). \quad (9)$$

where λ denotes the longitude of the study location and λ_{std} is the standard longitude corresponding to the local time zone.
The solar time is calculated as
$$ST(t) = LT(t) + \frac{TC(t)}{60}. \quad (10)$$
where $LT(t)$ represents the local clock time. The corresponding solar hour angle is
$$\omega(t) = 15°[ST(t) - 12]. \quad (11)$$
The cosine of the solar zenith angle is determined as
$$cos\theta_z(t) = sin\varphi sin\delta(t) + cos\varphi cos\delta(t) cos\omega(t). \quad (12)$$
where φ denotes the latitude of the study location. The direct normal irradiance (DNI) is obtained from the beam horizontal irradiance (BHI) according to
$$DNI(t) = \frac{BHI(t)}{cos\theta_z(t)}. \quad (13)$$
for periods during which the sun is above the horizon.

Plane-of-Array Irradiance (POA) Model
For a PV surface having the tilt angle β and the azimuth angle γ, the cosine of the incidence angle is calculated as (Barbón et al., 2022; Sunderan et al., 2011)
$$cos\theta_i(t) = sin\delta(t) sin\varphi cos\beta - sin\delta(t) cos\varphi sin\beta cos\gamma + cos\delta(t) cos\varphi cos\beta cos\omega(t) + cos\delta(t) sin\varphi sin\beta cos\gamma cos\omega(t) + cos\delta(t) sin\beta sin\gamma sin\omega(t). \quad (14)$$
Only positive incidence-angle contributions are considered, such that
$$cos\theta_i(t) = \max[cos\theta_i(t), 0]. \quad (15)$$
The beam component incident on the tilted PV surface is
$$G_{b,POA}(t) = DNI(t) cos\theta_i(t). \quad (16)$$
Using the isotropic diffuse-sky model, the diffuse component is
$$G_{d,POA}(t) = DHI(t) \frac{1+cos\beta}{2}. \quad (17)$$
where $DHI(t)$ denotes diffuse horizontal irradiance. The ground-reflected component is calculated as
$$G_{r,POA}(t) = \rho_g GHI(t) \frac{1-cos\beta}{2}. \quad (18)$$
where ρ_g is the ground reflectance and $GHI(t)$ represents global horizontal irradiance. The total POA irradiance is therefore given by
$$G_{POA}(t, \beta, \gamma) = G_{b,POA}(t) + G_{d,POA}(t) + G_{r,POA}(t). \quad (19)$$

Maximization of Annual POA Irradiation
The first objective function considered in this study is the maximization of annual POA irradiation. Let τ_m denote the set of hourly observations belonging to month m. Since one orientation is used throughout each month, the monthly POA irradiation is computed by
$$H_m(\beta_m, \gamma_m) = \sum_{t \in \tau_m} G_{POA}(t, \beta_m, \gamma_m) \Delta t. \quad (20)$$
where $\Delta t = 1\ h$ for the hourly dataset. The total annual POA irradiation is
$$H_{annual} = \sum_{m=1}^{12} H_m(\beta_m, \gamma_m). \quad (21)$$
For the joint tilt-azimuth case,
$$H_{TA} = \sum_{m=1}^{12} H_m(\beta_m, \gamma_m). \quad (22)$$
whereas for the tilt-only case,
$$H_T = \sum_{m=1}^{12} H_m(\beta_m, 0°). \quad (23)$$
The first objective function of both optimization problems is therefore expressed by
$$\max f_1 = H_{annual}. \quad (24)$$

Adjustment Effort Index
The second objective function is used to quantify the practical burden associated with changing the PV orientation. The absolute change in tilt angle between two consecutive months is defined as
$$\Delta\beta_m = |\beta_m - \beta_{m-1}|, m = 2, \dots, 12. \quad (25)$$
Since azimuth is a circular variable, the physical azimuth displacement is calculated using the shortest angular distance,
$$\Delta\gamma_m = \min[|\gamma_m - \gamma_{m-1}|, 360° - |\gamma_m - \gamma_{m-1}|]. \quad (26)$$
Accordingly,

$0° \leq \Delta\gamma_m \leq 180°.$ (27)

An orientation-adjustment indicator is defined as

$$u_m = \begin{cases} 1, & \Delta\beta_m + \Delta\gamma_m > 0 \\ 0, & otherwise \end{cases}. \quad (28)$$

The annual number of orientation adjustments is

$N_{adj} = \sum_{m=2}^{12} u_m.$ (29)

With monthly orientation scheduling, at most 11 month-to-month transitions can occur. Therefore, the normalized adjustment-frequency component is

$I_N = \frac{N_{adj}}{11}.$ (30)

Since the maximum possible tilt displacement during one transition is 90°, the normalized cumulative tilt movement is

$I_\beta = \frac{\sum_{m=2}^{12} \Delta\beta_m}{11\times 90°}.$ (31)

Similarly, since the maximum azimuth displacement during one transition is 180°, the normalized cumulative azimuth movement is

$I_\gamma = \frac{\sum_{m=2}^{12} \Delta\gamma_m}{11\times 180°}.$ (32)

A common AEI formulation is employed for both orientation strategies:

$AEI = \omega_N I_N + \omega_\beta I_\beta + \omega_\gamma I_\gamma.$ (33)

where ω_N, ω_β, and ω_γ denote the weighting coefficients associated with adjustment frequency, cumulative tilt movement, and cumulative azimuth movement, respectively. For the tilt-only case, the azimuth angle remains constant and hence $I_\gamma = 0$.

Equal weighting is adopted for the baseline analysis,

$\omega_N = \omega_\beta = \omega_\gamma = 1.$ (34)

The second objective is therefore expressed as

$\min f_2 = AEI.$ (35)

Multi-Objective Formulation

For the joint tilt-azimuth strategy, the optimization problem is

$$\max_{\mathbf{x}_{TA}} H_{TA}$$
$$\min_{\mathbf{x}_{TA}} AEI_{TA}. \quad (36)$$

subject to

$0° \leq \beta_m \leq 90°\ , -180° \leq \gamma_m \leq 180°.$ (37)

For the tilt-only strategy,

$$\max_{\mathbf{x}_T} H_T$$
$$\min_{\mathbf{x}_T} AEI_T. \quad (38)$$

subject to

$0° \leq \beta_m \leq 90°\ , \gamma_m = 0°.$ (39)

To enforce the adopted 1° angular resolution, candidate orientation variables generated during the optimization are rounded to the nearest integer before evaluation using the monthly POA lookup table.

Methodology

Monthly POA Lookup Table

Direct calculation of hourly POA irradiation for every candidate individual generated during the optimization process would require a large number of repeated solar-geometry calculations. Therefore, a preprocessing procedure is employed as described below. The POA irradiation is evaluated for all integer combinations within

$\beta \in \{0°, 1°, \dots, 90°\}, \gamma \in \{-180°, -179°, \dots, 180°\}$ (40)

For each (β, γ) pair, the hourly POA values are calculated using Eq. (19). These hourly values are then aggregated separately for every month, resulting in the lookup table.

$H_m(\beta, \gamma), m = 1, \dots, 12.$ (41)

For any candidate monthly orientation schedule, annual irradiation can therefore be obtained directly for tilt-azimuth and tilt-only cases as given in Eqs. (22) and (23), respectively.

Multi-Objective Optimization

The multi-objective optimization problems are solved using the controlled elitist multi-objective genetic algorithm implemented in MATLAB (MathWorks, 2024). The tilt-only problem is first solved to obtain its Pareto-optimal candidate solutions. For the larger joint tilt-azimuth search space, both unseeded and partially seeded optimization runs are performed to preserve global exploration while improving the representation of low-adjustment-effort regions. The tilt-only Pareto solutions are additionally embedded in the joint feasible space by setting all azimuth angles to 0°. The resulting candidate solutions are merged and subjected to non-dominated filtering to obtain the final joint Pareto front. The joint tilt-azimuth problem contains 24 decision variables, whereas the tilt-only optimization contains 12 decision variables. Candidate orientation schedules are evaluated using the two objective functions defined by $\mathbf{F}_{TA} = [-H_{TA}, AEI_{TA}]$ and $\mathbf{F}_{T} = [-H_{T}, AEI_{T}]$. The negative signs are applied to H_{TA} and H_T to transform the maximization objectives to the minimization form. The optimization produces a set of non-dominated solutions rather than a single operating point. A solution x^A dominates another solution x^B if it is no worse than in both objectives and strictly better in at least one objective. The set of non-dominated solutions constitutes the Pareto-optimal set. Each Pareto solution therefore represents a different compromise between annual POA and adjustment effort.

Compromise Solution Selection

A representative compromise operating point is determined from each Pareto front using normalization and Euclidean distance to an ideal point. The annual POA irradiation of solution i is normalized as

$$H_{norm,i} = \frac{H_i - H_{min}}{H_{max} - H_{min}}. \quad (42)$$

The corresponding AEI is normalized according to

$$AEI_{norm,i} = \frac{AEI_i - AEI_{min}}{AEI_{max} - AEI_{min}}. \quad (43)$$

The normalized ideal point is $(H_{norm,}\, AEI_{norm,}) = (1, 0)$ representing simultaneous maximum irradiation and minimum adjustment effort. The Euclidean distance of Pareto solution i from the ideal point is

$$d_i = \sqrt{\left(1 - H_{norm,i}\right)^2 + AEI_{norm,i}^2}. \quad (44)$$

The representative compromise solution is then selected as

$$i^* = \underset{i}{\operatorname{argmin}}\, d_i. \quad (45)$$

Comparison Metrics

Maximum-Irradiation Benefit of Azimuth Optimization

The maximum achievable irradiation benefit obtained by allowing azimuth optimization is quantified as

$$\Delta H_{\gamma,max} = H_{TA,max} - H_{T,max}. \quad (46)$$

and its percentage value is given by

$$G_{\gamma,max} = \frac{H_{TA,max} - H_{T,max}}{H_{T,max}} \times 100. \quad (47)$$

The corresponding irradiation-retention ratio of the tilt-only strategy is defined as

$$R_{T,max} = \frac{H_{T,max}}{H_{TA,max}} \times 100. \quad (48)$$

Compromise Solution Comparison

For the independently selected compromise solutions, the irradiation difference is

$$\Delta H_{\gamma,c} = H_{TA,c} - H_{T,c}. \quad (49)$$

where the subscript c denotes the compromise solution. The percentage irradiation benefit of azimuth optimization is

$$G_{\gamma,c} = \frac{H_{TA,c} - H_{T,c}}{H_{T,c}} \times 100. \quad (50)$$

The irradiation-retention ratio of tilt-only optimization is

$$R_{T,c} = \frac{H_{T,c}}{H_{TA,c}} \times 100. \quad (51)$$

The compromise points are selected independently from their respective Pareto fronts and therefore do not necessarily correspond to identical AEI values. Consequently, differences between their AEI values are reported descriptively rather than used to construct a marginal irradiation-per-AEI indicator.

Equal-AEI Comparison

Since the two Pareto fronts are generated independently, their individual compromise points do not necessarily represent the same adjustment-effort level. Therefore, an equal-AEI comparison is used for a more direct evaluation. For a prescribed adjustment-effort budget AEI_b, the maximum achievable annual irradiation of the joint tilt-azimuth strategy is

$$H_{TA}^*(AEI_b) = \max_{\mathbf{x}_{TA}} \{H_{TA} : AEI_{TA} \le AEI_b\}. \quad (52)$$

Similarly, the maximum annual irradiation of the tilt-only strategy is

$$H_T^*(AEI_b) = \max_{\mathbf{x}_T} \{H_T : AEI_T \le AEI_b\}. \quad (53)$$

Feasible-Set Consistency

The tilt-only feasible set constitutes a subset of the joint tilt–azimuth feasible set. Specifically, every feasible tilt-only solution can be represented within the joint formulation by imposing

$$\gamma_1 = \gamma_2 = \cdots = \gamma_{12} = 0°. \quad (54)$$

For this embedded solution,

$$I_\gamma = 0. \quad (55)$$

and therefore, both its POA irradiation and AEI are identical to those of the corresponding tilt-only solution.

Consequently, for any common AEI budget AEI_b, the globally optimal solutions must satisfy

$$H_{TA}^*(AEI_b) \ge H_T^*(AEI_b) \quad (56)$$

Equation (56) provides an important consistency condition for the numerical optimization. If the numerically approximated tilt-azimuth Pareto front produces a lower irradiation than the tilt-only front under the same AEI budget, this does not represent a physical disadvantage of azimuth flexibility. Instead, it indicates that the larger joint search space has not been sufficiently sampled in that region of the Pareto front.

Azimuth Benefit Under Equal Adjustment Effort

The absolute irradiation benefit provided by azimuth flexibility at the same AEI budget is defined as

$$\Delta H_\gamma(AEI_b) = H_{TA}^*(AEI_b) - H_T^*(AEI_b). \quad (57)$$

The corresponding percentage benefit is

$$G_\gamma(AEI_b) = \frac{H_{TA}^*(AEI_b) - H_T^*(AEI_b)}{H_T^*(AEI_b)} \times 100. \quad (58)$$

For a sufficiently converged solution of the two optimization problems,

$$G_\gamma(AEI_b) \ge 0. \quad (59)$$

A zero value indicates that the additional azimuth degree of freedom provides no irradiation improvement at the considered adjustment budget, whereas a positive value quantifies the additional solar resource captured through azimuth flexibility.

The proposed formulation evaluates PV orientation through two conflicting objectives: maximizing annual POA irradiation and minimizing orientation-adjustment effort. A unified AEI is employed for both tilt–azimuth and tilt-only optimization, allowing the two strategies to be compared on a consistent basis. The tilt-only configuration is mathematically embedded within the joint tilt–azimuth formulation by fixing all azimuth angles to 0◦. This nested feasible-set relationship establishes an important theoretical condition: at an identical AEI budget, the joint optimization cannot provide lower globally optimal irradiation than the tilt-only configuration. Accordingly, the final comparison is performed using maximum-irradiation solutions, independently selected compromise solutions, cumulative orientation movements, and equal-AEI performance. This formulation enables the additional irradiation benefit of azimuth flexibility to be quantified while simultaneously considering the practical burden associated with panel reorientation.

Findings and Discussion

This section first presents the measured solar irradiance data used as the input to the optimization framework and then evaluates the resulting multi-objective PV orientation solutions. The hourly GHI, DHI, and BHI data obtained from the RERH at Eskişehir Technical University (Filik et al., 2018), as shown in Fig. 1, are followed by a comparative assessment of the tilt-azimuth and tilt-only strategies in terms of POA irradiation, AEI, Pareto performance, and optimal monthly orientation schedules.

Optimization Performance

The multi-objective optimization is performed for two orientation strategies. In the first case, both the tilt and azimuth angles are allowed to vary on a monthly basis, whereas in the second case only the tilt angle is optimized while the azimuth angle is fixed at 0°. The resulting solutions quantify the trade-off between POA irradiation and AEI. Table 1 summarizes the maximum-irradiation and compromise solutions obtained for the two strategies. The joint tilt-azimuth optimization achieves a maximum annual POA irradiation of 1841.8 kWh/m^2, compared with 1796.9 kWh/m^2 for the tilt-only strategy. Thus, incorporating azimuth as an additional decision variable increases maximum attainable irradiation by 44.9 kWh/m^2, corresponding to a relative improvement of 2.50%. Despite the restriction imposed by fixing the azimuth angle, the tilt-only configuration retains 97.6% of the maximum irradiation attainable through joint orientation optimization.

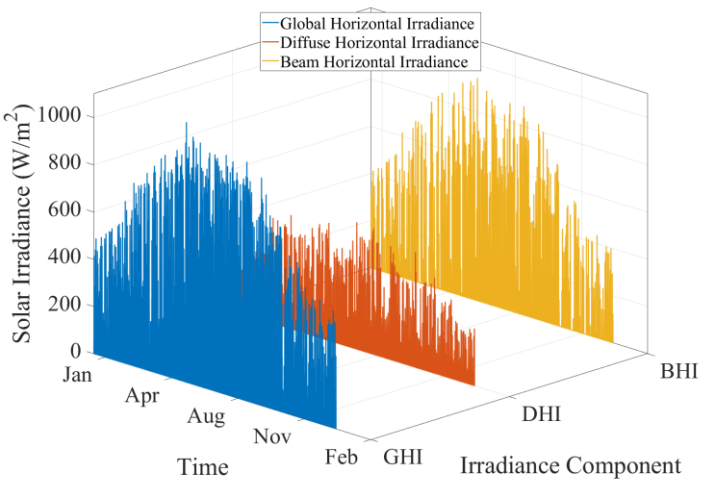

Figure 1. Hourly GHI, DHI, and BHI data obtained from the RERH at the Iki Eylul Campus of Eskişehir Technical University.

Table 1. Comparison of Two Optimization Strategies

Performance Indicator	Tilt-Azimuth	Tilt-Only
Maximum POA irradiation (kWh/m²)	1841.8	1796.9
AEI at maximum POA	1.0934	1.0919
Adjustments at maximum POA	11	11
Compromise POA irradiation (kWh/m²)	1825.0	1790.9
Compromise AEI	0.6061	0.6141
Compromise adjustments	6	6
Cumulative tilt movement (°)	29	68
Cumulative azimuth movement (°)	62	0

The maximum-irradiation solutions require 11 orientation adjustments in both cases, indicating that maximum solar-energy capture favors frequent orientation. However, the additional irradiation obtained by permitting azimuth adjustment is relatively modest compared with the increased mechanical flexibility required by a two-axis adjustable structure. Consequently, maximizing irradiation alone does not provide sufficient information for selecting an orientation strategy. This observation motivates the inclusion of adjustment effort as a second objective and the examination of the resulting Pareto-optimal solutions.

The minimum-AEI endpoint provides the opposite extreme. At $AEI = 0$, both optimization strategies yield exactly 1584.2 kWh/m^2. This equality is expected because zero adjustment effort eliminates the benefit of monthly reorientation and is consistent with the common zero-adjustment configurations available to both formulations.

Pareto Trade-Off Between Irradiation and Adjustment Effort

Fig. 2 presents the Pareto fronts obtained for the two optimization strategies. The figure clearly demonstrates the conflicting nature of the objectives: higher annual POA irradiation generally requires a higher AEI. The solutions are distributed from low-effort configurations with annual irradiation around 1584-1630 kWh/m^2 to more actively adjusted configurations approaching 1800 kWh/m^2 for tilt-only optimization and approximately 1842 kWh/m^2 when both orientation variables are optimized. The most important characteristic of Fig. 2 is that the joint tilt-azimuth formulation expands the achievable objective space. At very low adjustment effort, the two methods provide similar performance because there is insufficient adjustment freedom for the azimuth degree of freedom to provide a substantial benefit. As AEI increases, however, the joint optimization increasingly outperforms the tilt-only configuration. This indicates that azimuth flexibility becomes particularly beneficial when a moderate or high level of seasonal reorientation is permitted.

The discontinuous structure of the Pareto fronts stems from the fact that AEI contains a component associated with the number of orientation interventions; consequently, increasing the number of adjustments introduces discrete changes in the objective. The Pareto front therefore does not necessarily evolve as a smooth continuous curve. Instead, clusters of solutions occur for configurations having similar numbers of orientation interventions.

Comparison at Equal Adjustment Effort

A direct comparison of independently selected Pareto solutions may be misleading because the solutions can have different AEI values. Therefore, the two optimization strategies are additionally evaluated under identical maximum allowable AEI budgets. Fig. 3 presents the maximum achievable POA irradiation for each strategy as the AEI budget is progressively increased.

The equal-AEI comparison provides particularly strong evidence for the benefit of joint orientation optimization. At an AEI budget of approximately 0.11, the joint strategy produces 1598.2 kWh/m^2, whereas the tilt-only strategy produces 1588.9 kWh/m^2, corresponding to an improvement of approximately 0.585%. At an AEI of approximately 0.20, the respective values increase to 1616.5 and 1607.8 kWh/m^2.

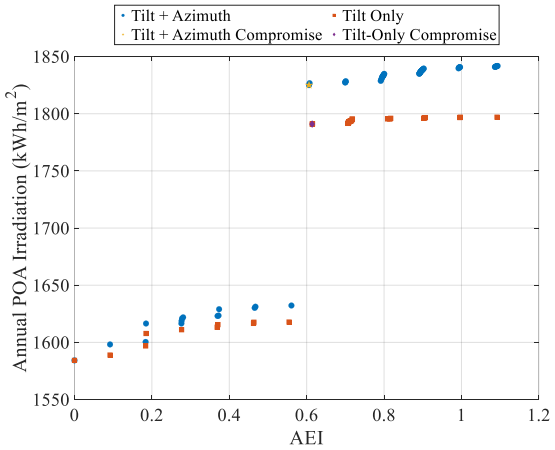

Figure 2. Pareto fronts of annual POA irradiation and AEI for the tilt-azimuth and tilt-only optimization strategies.

The benefit becomes considerably more pronounced as the allowable adjustment effort increases. For example, at an AEI of approximately 0.80, the joint optimization reaches 1834.9 kWh/m^2, compared with 1795.4 kWh/m^2 for tilt-only optimization, yielding an improvement of approximately 2.20%. At an AEI budget of 1.0919, the corresponding values are approximately 1841.7 and 1797.0 kWh/m^2, respectively, resulting in an improvement of approximately 2.49%.

Importantly, the numerical nested-feasible-set check confirms that $H_{TA}^{*}(AEI_b) \geq H_{T}^{*}(AEI_b)$ for every evaluated AEI budget where $H_{TA}^{*}(AEI_b)$ and $H_{T}^{*}(AEI_b)$ denote the best attainable irradiation for the joint tilt–azimuth and tilt-only strategies, respectively. Consistent with the nested feasible-set property, the best joint solution obtained at each evaluated AEI budget was never inferior to the corresponding tilt-only solution. Theoretically, this condition follows because every tilt-only schedule remains feasible within the joint formulation. This is an important practical result. It demonstrates that the benefit of azimuth optimization is not merely caused by permitting the two-axis system to perform more adjustments. Instead, even when the two systems are subjected to the same AEI constraint, the additional orientation degree of freedom allows the available adjustment effort to be allocated more effectively.

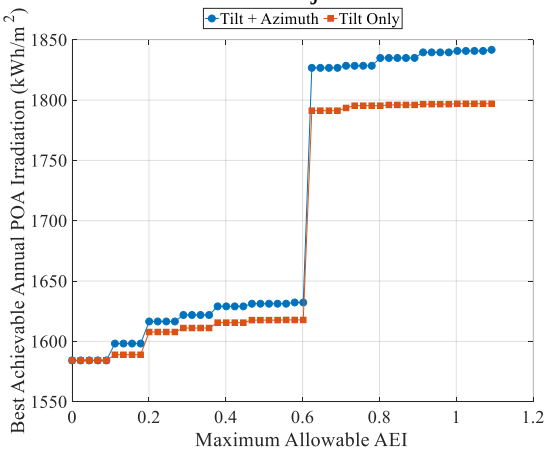

Figure 3. Best achievable annual POA irradiation under identical maximum allowable AEI values.

Relative Benefit of Azimuth Optimization

The irradiation advantage provided by azimuth optimization as a function of AEI is illustrated in Fig. 4. At very low AEI values, the advantage is essentially zero because both systems remain close to their low-adjustment configurations. Once adjustment effort is permitted, however, the benefit becomes positive and generally increases with AEI.

The relative benefit initially remains below approximately 1%, but increases substantially once the AEI approaches 0.6. The improvement subsequently reaches approximately 2.0%, exceeds 2.2% around an AEI of 0.80, and approaches 2.5% near the maximum investigated adjustment effort. This trend indicates that azimuth optimization becomes increasingly valuable as greater orientation flexibility is allowed. In other words, a system designed for almost fixed operation receives little benefit from adding azimuth adjustability, whereas a system intended for periodic manual or mechanical reorientation can exploit the second orientation degree of freedom more effectively.

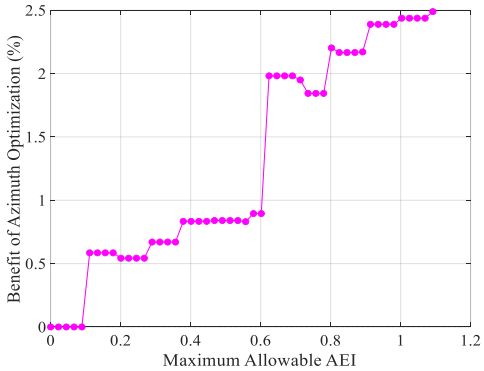

Figure 4. Relative irradiation benefit obtained by including azimuth optimization at equal AEI

Compromise Solutions

The compromise solution represents a more practically relevant operating point than the maximum-irradiation endpoint because it simultaneously accounts for energy capture and orientation effort. The joint tilt-azimuth compromise solution provides an annual POA irradiation of 1825 kWh/m^2 at an AEI of 0.6061, whereas the tilt-only compromise solution provides 1790.9 kWh/m^2 at an AEI of 0.6141. Both configurations require six orientation adjustments. Therefore, joint optimization increases annual irradiation by $\Delta H = 1825 - 1790.9 = 34.1$ kWh/m^2, which corresponds to an improvement of 1.901%.

Moreover, this improvement is achieved with a slightly lower AEI. The difference between the compromise AEI values is -0.008, while the tilt-only strategy retains 98.135% of the irradiation obtained from the joint compromise solution. This result is significant because the benefit of azimuth optimization is obtained without increasing the number of physical interventions. Both systems require six adjustments over the year. Instead, the additional degree of freedom allows the orientation movement to be distributed between tilt and azimuth. The cumulative tilt movement decreases substantially from 68° in the tilt-only system to only 29° in the joint system, while the latter introduces 62° of cumulative azimuth movement. Thus, the optimization does not simply add azimuth movement on top of an unchanged tilt schedule. It produces a fundamentally different orientation trajectory in which tilt and azimuth adjustments complement one another.

Monthly Orientation Characteristics

Fig. 5 compares the monthly tilt angles associated with the two compromise solutions. The tilt-only solution exhibits a pronounced seasonal variation. The panel tilt decreases from 49° in January to 17° during May-August and subsequently increases to 53° in November and December. In contrast, the joint optimization results in a considerably narrower tilt range. The optimized tilt is 41° in January and February, decreases gradually to 27° during May-August, and subsequently increases to approximately 42° during October-December. This explains the substantially smaller cumulative tilt displacement of the joint solution.

The reduction in tilt variation occurs because part of the seasonal orientation correction is transferred to the azimuth axis. As shown in Fig. 6, the compromise azimuth angles vary from approximately -10° during the winter months to approximately -41° during May-July before returning toward -10° toward the end of the year.

This behavior demonstrates an important characteristic of multi-axis orientation optimization: the tilt and azimuth angles should not necessarily be optimized independently. Rather, they form a coupled orientation decision. Allowing azimuth variation changes the optimal tilt trajectory itself, which explains why the joint solution requires only 29° of cumulative tilt displacement compared with 68° for the tilt-only configuration.

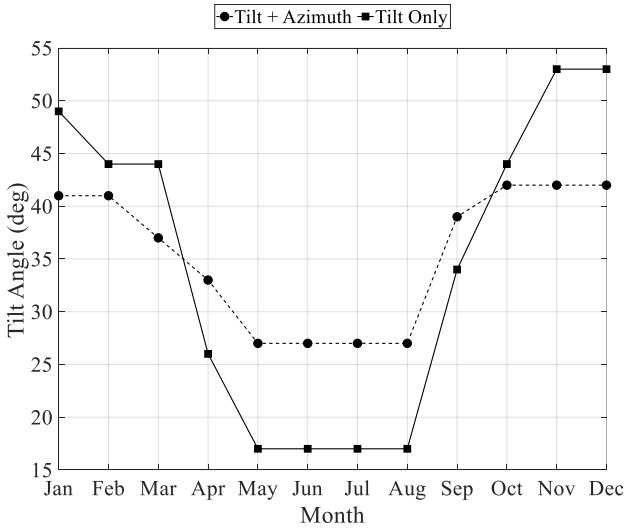

Figure 5. Monthly tilt angles corresponding to the compromise solutions of the two optimization strategies.

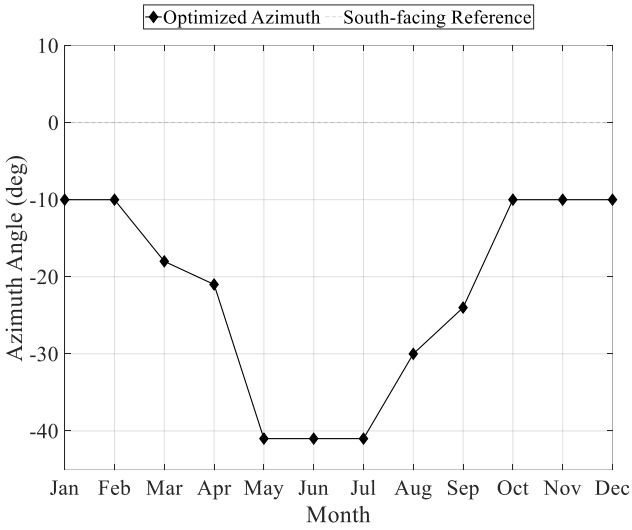

Figure 6. Monthly azimuth angles corresponding to the compromise solution of the joint tilt-azimuth optimization.

Conclusion

This study developed a multi-objective optimization framework for determining monthly PV orientations by simultaneously maximizing annual POA irradiation and minimizing the effort associated with orientation adjustments. The proposed AEI provides a common measure of adjustment requirements by considering both the number of orientation interventions and the cumulative angular movements. Two orientation strategies were investigated: joint optimization of monthly tilt and azimuth angles and tilt-only optimization with a fixed south-facing azimuth.

The results demonstrated a clear trade-off between solar irradiation capture and orientation adjustment effort. Joint tilt-azimuth optimization achieved a maximum annual POA irradiation of 1841.8 kWh/m², compared with 1796.9 kWh/m² for tilt-only optimization, corresponding to an improvement of approximately 2.50%. For the selected compromise solutions, the annual POA irradiation increased from 1790.9 kWh/m² for the tilt-only strategy to 1825.0 kWh/m² for the joint strategy, representing an improvement of approximately 1.90%. Both compromise solutions required only six orientation interventions over the year. Furthermore, the joint strategy reduced the cumulative tilt movement from 68° to 29° by distributing the required orientation changes between the tilt and azimuth degrees of freedom.

The equal-AEI analysis further showed that the additional azimuth degree of freedom can provide higher attainable POA irradiation without requiring a greater overall adjustment effort. Therefore, the benefit of azimuth optimization should not be assessed solely from the maximum achievable irradiation, but rather by considering its interaction with the practical effort required for periodic reorientation. Overall, the proposed framework provides a systematic approach for balancing solar irradiation capture and adjustment requirements and can support the design and operation of periodically adjustable PV systems. Future studies may extend the framework by incorporating PV power-generation characteristics, economic costs associated with orientation adjustments, different climatic conditions, and experimentally implemented adjustment mechanisms.

ABSTRACT
Metalenses are flat lenses composed of subwavelength meta-atoms that manipulate the incident wavefront to focus light at a desired point. In metalens design, the choice of material for the meta-atoms plays a key role in the focusing performance and manufacturability of a metalens. Accordingly, over the past decade, numerous plasmonic, alternative plasmonic, and all-dielectric based metalens designs have been developed in the visible and near-infrared (NIR) spectral ranges, and their focusing performances have been systematically demonstrated. Gallium phosphide (GaP) is also a high-refractive-index dielectric material and offers strong light confinement capabilities. In the visible and NIR region, GaP exhibits a high refractive index combined with low optical absorption. These properties make it a promising alternative to commonly used high-index dielectric materials for metasurface-based applications. Despite these advantages, GaP-based metalens designs remain limited in the literature, especially in the NIR regime. This gap indicates an opportunity to explore GaP as a practical and high-performance platform for metalens implementations. In this work, the focal-length-dependent performance of fixed-aperture GaP metalenses is systematically investigated at 850 nm using full-wave electromagnetic simulations. Three metalenses with an identical diameter of 200 μm and focal lengths of 1000, 500, and 200 μm were designed, corresponding to numerical apertures (NA) of 0.10, 0.196, and 0.45, respectively. The simulated average focal spot full-width half-maximums (FWHM) were 4.30, 2.23, and 1.00 μm, with corresponding depths of focus (DOF) of 145.5, 38.1, and 7.1 μm. The absolute focusing efficiencies were also calculated as 71%, 67%, and 50%, respectively, revealing reduced efficiency as stronger confinement was achieved at higher NA. Overall, the results establish a quantitative resolution–DOF–efficiency trade-off for GaP metalenses at 850 nm and characterize GaP as a promising dielectric platform for NIR flat-optical systems.

Abstract
Proper headlamp alignment and adequate lighting performance are essential for safe night-time driving. Incorrectly aimed or excessively bright headlamps can impair the visibility of other road users and increase glare-related safety risks. Conventional headlamp inspection is generally carried out during periodic vehicle inspections using dedicated aiming equipment while the vehicle is stationary. Consequently, changes or faults occurring after inspection cannot be effectively monitored under normal traffic conditions. This paper presents a remote measurement and inspection system designed to evaluate the headlamp alignment and lighting characteristics of moving vehicles without interrupting traffic flow. The system combines photometric imaging, optical sensing, image processing, and automatic number plate recognition capabilities. Measurement units can be deployed beside or above the roadway, as well as on mobile platforms, allowing the system to operate under real-world driving conditions. Headlamp emissions are captured and processed to determine parameters including vertical alignment, optical axis angle, luminous intensity, spatial light distribution, and color temperature. The measured parameters are evaluated against predefined reference limits based on vehicle type and applicable national and international lighting standards. This enables the automatic identification of conditions such as incorrect headlamp alignment, insufficient or excessive light output, abnormal light distribution, and inactive headlamps. When a non-compliant lighting condition is identified, the vehicle number plate is automatically detected and associated with the corresponding measurement data. The system can also transmit measurement and violation records to central inspection and monitoring systems through wired or wireless communication technologies. The developed system provides a practical framework for non-contact and remote monitoring of vehicle lighting performance under real-world traffic conditions and offers a potential solution for improving traffic safety and reducing headlamp-related glare.

Özet
Farların uygun şekilde hizalanması ve yeterli aydınlatma performansına sahip olması, gece sürüş güvenliği açısından büyük önem taşımaktadır. Yanlış hizalanmış veya aşırı parlak farlar, diğer yol kullanıcılarının görüşünü olumsuz etkileyebilmekte ve göz kamaşmasına bağlı güvenlik risklerini artırabilmektedir. Geleneksel far denetimleri genellikle periyodik araç muayeneleri sırasında, taşıt sabit durumdayken özel far ayar cihazları kullanılarak gerçekleştirilmektedir. Bu nedenle, muayene sonrasında meydana gelen değişikliklerin veya arızaların normal trafik koşullarında etkin bir şekilde izlenmesi mümkün olmamaktadır. Bu çalışmada, seyir hâlindeki taşıtların far hizalamasını ve aydınlatma özelliklerini trafik akışını kesintiye uğratmadan değerlendirmek üzere geliştirilen uzaktan bir ölçüm ve denetim sistemi sunulmaktadır. Sistem; fotometrik görüntüleme, optik algılama, görüntü işleme ve otomatik plaka tanıma yeteneklerini bir araya getirmektedir. Ölçüm birimleri yol kenarına, yol üstüne veya mobil platformlar üzerine yerleştirilebilmekte ve böylece sistemin gerçek sürüş koşullarında çalışmasına olanak sağlanmaktadır. Far ışığı yakalanarak işlenmekte ve düşey hizalama, optik eksen açısı, ışık şiddeti, uzamsal ışık dağılımı ve renk sıcaklığı gibi parametreler belirlenmektedir. Elde edilen ölçüm parametreleri, taşıt türüne bağlı olarak tanımlanan referans sınır değerler ve geçerli ulusal ve uluslararası aydınlatma standartları ile karşılaştırılmaktadır. Böylece far hizasının uygun olmaması, yetersiz veya aşırı ışık çıkışı, anormal ışık dağılımı ve çalışmayan farlar gibi durumların otomatik olarak belirlenmesi sağlanmaktadır. Mevzuata uygun olmayan bir aydınlatma durumu tespit

edildiğinde, taşıtın plaka bilgisi otomatik olarak belirlenerek ilgili ölçüm verileriyle ilişkilendirilmektedir. Sistem ayrıca ölçüm ve ihlal kayıtlarını kablolu veya kablosuz haberleşme teknolojileri üzerinden merkezi denetim ve izleme sistemlerine aktarabilmektedir. Geliştirilen sistem, gerçek trafik koşullarında taşıtların aydınlatma performansının temassız ve uzaktan izlenmesi için uygulanabilir bir altyapı sağlamakta ve trafik güvenliğinin artırılması ile far kaynaklı göz kamaşmasının azaltılmasına yönelik potansiyel bir çözüm sunmaktadır.

ABSTRACT
This study focuses on developing a compact, economical, and manufacturable transformer design with a conventional oil-type On-Load Tap Changer (OLTC), as an alternative to the conventional radiator-cooled power transformer configuration. Oil-immersed transformers consist of integrated components, including windings, core, insulation materials, insulating oil, mechanical parts, and accessories. In transformers equipped with OLTCs, the cooling arrangement and installation volume can significantly affect overall dimensions, weight, oil volume, and cost. Increasing market competition and demand for compact, cost-effective transformer solutions have therefore increased the importance of optimizing existing designs.
Conventional oil-type transformers equipped with OLTCs are generally designed with radiator-based cooling systems. The use of radiators may result in increased external dimensions, higher oil volume and overall weight, as well as additional manufacturing, transportation, and installation costs. Within the scope of this project, a corrugated-wall tank design is developed as an alternative to this configuration. By incorporating the cooling surface directly into the transformer tank, the proposed design aims to eliminate external radiators and achieve a more compact transformer configuration.
The developed transformer design considers the electrical, thermal, and mechanical requirements of the system while providing reliable integration of the OLTC. The manufacturability of the proposed configuration and its performance under operating conditions are verified through manufacturing and testing activities.
As a result, the project presents an alternative design approach for reducing the dimensions, weight, and oil volume of conventional oil-type transformers equipped with OLTCs. The developed corrugated-wall transformer has significant potential to reduce manufacturing and material costs while providing advantages in lead time, transportation, and installation compared with conventional radiator-cooled designs. The proposed solution offers a technically feasible approach for developing more compact and cost-effective OLTC-equipped transformers.

ÖZET

Protein tirozin fosfataz 1B (PTP1B), insülin reseptörü ile insülin reseptör substratlarını defosforile ederek insülin sinyalini baskılayan ve leptin yolağındaki JAK2'yi hedef alarak enerji dengesini düzenleyen bir negatif düzenleyicidir. Bu çifte rolü nedeniyle tip 2 diyabet ve obezite tedavisinde doğrulanmış bir terapötik hedef olarak kabul edilmektedir. Ancak enzimin derin, dar ve pozitif yüklü katalitik cebinin PTP ailesi genelinde yüksek oranda korunmuş olması seçici inhibitör tasarımını güçleştirmekte; fosfotirozin taklidi ilk nesil bileşiklerin anyonik yapısı ise zayıf hücre geçirgenliği ve düşük oral biyoyararlanıma yol açmaktadır. Nitekim Faz II'ye ulaşabilen tek aday olan Ertiprotafib'in geliştirilmesi durdurulmuş olup, günümüzde klinik kullanıma onaylanmış bir PTP1B inhibitörü bulunmamaktadır. Bu çalışmada, PTP1B'nin katalitik bölgesini hedefleyen yeni inhibitör adaylarının farmakofor temelli sanal tarama yaklaşımıyla belirlenmesi amaçlanmıştır. Çalışmada hedef yapı olarak, katalitik cebine 6-(oksalilamino)-1H-indol-5-karboksilik asit (OAI) inhibitörü bağlı hâlde bulunan 1C83 kodlu PTP1B kristal yapısı kullanılmıştır. Yapı UCSF Chimera Dock Prep modülü ile kenetlenmeye hazırlanmış, OAI'nin bağlanma profili ayrıntılı biçimde incelenerek grid box parametreleri tanımlanmış ve oluşturulan protokol, OAI'nin aynı bölgeye yeniden kenetlenmesi (re-docking) yoluyla doğrulanmıştır. OAI'nin PTP1B ile kurduğu etkileşimler Pharmit platformunda analiz edilerek altı noktalı bir farmakofor sorgusu oluşturulmuş; bu sorgu ile ZINC Purchasable veritabanı taranarak 31.146 bileşikten oluşan bir ilaç kütüphanesi hazırlanmıştır. Kütüphane, PyRx arayüzünde çalıştırılan AutoDock Vina algoritması ile aynı bağlanma bölgesine kenetlenmiş, OAI, Ertiprotafib ve JTT-551 referans bileşikler olarak kullanılmıştır. Öne çıkan adayların ADME profilleri SwissADME, toksisite profilleri ise ProTox 3.0 çevrim içi sunucusunda öngörülmüştür. Yeniden kenetlenen OAI'nin kristal yapıdaki deneysel konformasyon ile 2 Å'ın altında RMSD sergilemesi ve kristal yapıdaki etkileşim ağını eksiksiz biçimde yeniden üretmesi, kurgulanan protokolü doğrulamıştır. Sanal tarama sonucunda -7 kcal/mol eşiğinin altında bağlanma enerjisi sergileyen ve katalitik cebin kritik rezidüleriyle anlamlı temas kuran 24 bileşik belirlenmiş; bunlar arasından ZINC000106540127 (-8,2 kcal/mol), ZINC000004879765 (-8,0 kcal/mol) ve ZINC000006760732 (-8,0 kcal/mol) en umut vaat edici adaylar olarak seçilmiştir. Üç bileşiğin de, birbirinden belirgin biçimde farklı kimyasal iskeletlere sahip olmalarına rağmen Tyr46, Asp181, Ala217 ve Arg221 rezidüleriyle ortak biçimde etkileşim kurduğu belirlenmiştir. ADME değerlendirmesinde adayların tamamı düşük molekül ağırlığı (246–299 g/mol), düşük lipofilisite (Log *P*o/w 0,71–1,01), yüksek gastrointestinal emilim ve "çözünür" sınıfında yer alan çözünürlük değerleri sergilemiş; hiçbirinin kan–beyin bariyerini geçmediği ve P-glikoprotein substratı olmadığı öngörülmüştür. Bu profil, aşırı lipofilik ve pratik olarak çözünmez yapıdaki Ertiprotafib ve JTT-551 ile belirgin bir karşıtlık oluşturmuştur. Toksisite analizinde ZINC000006760732, 1500 mg/kg LD50 değeri ile mutajenite ve karsinojenite açısından temiz profili sayesinde en elverişli güvenlik profilini sergilemiştir. Elde edilen bulgular, farmakofor temelli sanal taramanın PTP1B'nin katalitik cebine yönelik yeni kimyasal iskeletlerin belirlenmesinde etkili bir strateji olduğunu ortaya koymaktadır. Öne çıkan üç bileşik, bilinen inhibitörlere kıyasla üstün ilaç benzerliği ve farmakokinetik profil sergilemekte olup, moleküler dinamik simülasyonları ve deneysel doğrulama çalışmaları ile detaylandırılmaya aday niteliktedir.

Anahtar Kelimeler: PTP1B, tip 2 diyabet, farmakofor temelli sanal tarama, moleküler kenetlenme, in siliko ADME/toksisite öngörüsü

ABSTRACT

Protein tyrosine phosphatase 1B (PTP1B) is a negative regulator of insulin signalling that dephosphorylates the insulin receptor and insulin receptor substrates, and that also governs energy balance by targeting JAK2 downstream of the leptin receptor. This dual role has established the enzyme as a validated therapeutic target for type 2 diabetes and obesity. However, the deep, narrow and positively charged catalytic pocket of PTP1B is highly conserved across the PTP family, which complicates the design of selective inhibitors, while the anionic nature of first-generation phosphotyrosine-mimetic compounds results in poor cell permeability and low oral bioavailability. Indeed, Ertiprotafib, the only candidate to have reached Phase II, was discontinued, and no PTP1B inhibitor is currently approved for clinical use. The present study aimed to identify novel inhibitor candidates targeting the catalytic site of PTP1B through a pharmacophore-based virtual screening approach. The PTP1B crystal structure deposited under the code 1C83, which contains 6-(oxalylamino)-1H-indole-5-carboxylic acid (OAI) bound within its catalytic pocket, was selected as the target structure. The structure was prepared for docking using the Dock Prep module of UCSF Chimera, and the grid box parameters were defined by examining the binding profile of OAI in detail. The resulting protocol was validated by re-docking OAI into the same site. The interactions established between OAI and PTP1B were subsequently analysed in the Pharmit platform to construct a six-point pharmacophore query, and screening of the ZINC Purchasable database with this query yielded a compound library comprising 31,146 molecules. The library was docked into the same binding site using the AutoDock Vina algorithm implemented in PyRx, with OAI, Ertiprotafib and JTT-551 serving as reference compounds. ADME profiles of the prioritised candidates were predicted using the SwissADME server, and their toxicity profiles using the ProTox 3.0 server. The re-docked OAI pose deviated from the experimental conformation by less than 2 Å RMSD and fully reproduced the crystallographic interaction network, thereby validating the docking protocol. Virtual screening identified 24 compounds that exhibited binding energies below the -7 kcal/mol threshold while establishing meaningful contacts with the critical residues of the catalytic pocket. Among these, ZINC000106540127 (-8.2 kcal/mol), ZINC000004879765 (-8.0 kcal/mol) and ZINC000006760732 (-8.0 kcal/mol) were selected as the most promising candidates. Despite possessing markedly different chemical scaffolds, all three compounds engaged Tyr46, Asp181, Ala217 and Arg221 in common. ADME predictions indicated that all candidates combined low molecular weight (246–299 g/mol), low lipophilicity (Log Po/w 0.71–1.01), high gastrointestinal absorption and solubility values falling within the "soluble" class, while none was predicted to cross the blood–brain barrier or to act as a P-glycoprotein substrate. This profile contrasted sharply with the highly lipophilic and practically insoluble reference inhibitors Ertiprotafib and JTT-551. In the toxicity analysis, ZINC000006760732 displayed the most favourable safety profile, with an LD50 of 1500 mg/kg together with negative predictions for both mutagenicity and carcinogenicity. These findings demonstrate that pharmacophore-based virtual screening is an effective strategy for identifying novel chemical scaffolds directed against the catalytic pocket of PTP1B. The three prioritised compounds display superior drug-likeness and pharmacokinetic profiles compared with the known inhibitors, and represent suitable candidates for further characterisation through molecular dynamics simulations and experimental validation.

Keywords: PTP1B, type 2 diabetes, pharmacophore-based virtual screening, molecular docking, in silico ADME/toxicity prediction

1. GİRİŞ

PTPN1 geni tarafından kodlanan protein tirozin fosfataz 1B (PTP1B), PTP süper ailesinin ~50 kDa ağırlığındaki, transmembran olmayan ve ilk karakterize edilen üyelerinden biridir (Liu ve ark., 2022). Endoplazmik retikulumun sitoplazmik yüzeyine bağlı konumlanan enzim, insülin sinyalinin başlıca negatif düzenleyicisi olarak işlev görmektedir. Aktive olmuş insülin reseptörü ile IRS-1/IRS-2'yi defosforile ederek PI3K/Akt aracılı glukoz alımını azaltmaktadır (Abdelsalam, Korashy, Zeidan ve Agouni, 2019; Sun, Dinenno, Tang ve Kontaridis, 2024). Leptin reseptörü altındaki JAK2'yi defosforile ederek hipotalamik STAT3 aktivasyonunu sınırlandırmakta, böylece tokluk hissi ve enerji harcamasını da etkilemektedir (Kołodziej-Sobczak, Sobczak ve Łączkowski, 2024). Bu çifte rol, PTP1B eksikliği olan farelerde gözlenen artmış insülin duyarlılığı, iyileşmiş glukoz toleransı ve diyetle indüklenen obeziteye direnç ile doğrulanmıştır (Elchebly ve ark., 1999; Klaman ve ark., 2000).

Bu düzenleyici konumu nedeniyle PTP1B disregülasyonu geniş bir hastalık yelpazesiyle ilişkilendirilmektedir. Karaciğer, kas ve hipotalamik nöronlardaki artmış aktivitesi tip 2 diyabet ve obezitede birleşik insülin-leptin direncine katkı sağlarken (Bence ve ark., 2006; Kołodziej-Sobczak ve ark., 2024), PI3K/eNOS aracılı nitrik oksit yolağını baskılayarak endotel disfonksiyonu ve kardiyovasküler hastalığa yol açmaktadır (Abdelsalam ve ark., 2019; Sun ve ark., 2024). Onkolojide daha bağlam-bağımlı bir rol üstlenmekte; HER2-pozitif meme kanserinde tümör başlangıcını tetikleyebilirken farklı dokularda tümör baskılayıcı gibi de davranabilmektedir (Kołodziej-Sobczak ve ark., 2024; Krishnan ve ark., 2014). Ayrıca Alzheimer, Parkinson ve majör depresif bozuklukla ilişkilendirilerek terapötik önemi metabolik hastalığın ötesine taşınmaktadır (Kołodziej-Sobczak ve ark., 2024).

Yapısal olarak 435 amino asitlik PTP1B; bir N-terminal katalitik domain (~1–300), bir düzenleyici segment (~300–400) ve enzimi ER membranına bağlayan hidrofobik bir C-terminal kuyruktan (~400–435) oluşmaktadır (Liu ve ark., 2022). Katalitik domain, aktif bölgeyi oluşturan esnek halkaların yer aldığı kompakt bir α/β katlanması sergilemektedir. Kataliz değişmez nükleofilik Cys215 kalıntısına dayanırken, WPD halkasının bağlanmış substrat üzerine kapanması reaksiyon döngüsünü tamamlamaktadır (Woods, Abzalimov ve Keedy, 2024). Derin, dar ve pozitif yüklü aktif bölge PTP ailesi genelinde yüksek oranda korunmuş olup seçici inhibitör tasarımını güçleştirmektedir. Bu kısıtlama, katalitik merkezden ~20 Å uzaklıktaki α7 heliks bölgesi ve içsel olarak düzensiz C-terminal segment gibi allosterik bağlanma yüzeylerinin araştırılmasını tetiklemiştir (Krishnan ve ark., 2014; Woods ve ark., 2024).

PTP1B-knockout modellerinden elde edilen genetik doğrulama ve farmakolojik inhibisyonun hepatik lipid birikimi olmaksızın glukoz homeostazını iyileştirdiğine dair bulgular, bu enzime yönelik iki on yılı aşkın süredir devam eden ilaç keşfi çabalarını desteklemektedir (Abdelsalam ve ark., 2019; Elchebly ve ark., 1999). Ancak aktif bölgeye yönelik ilk nesil fosfotirozin-mimetik inhibitörlerin polar, anyonik yapısı zayıf hücre geçirgenliği ve oral biyoyararlanıma yol açarak klinik ilerlemeyi sınırlandırmıştır (Liu ve ark., 2022). Faz II'ye ulaşan tek bileşik olan Ertiprotafib, hedef-dışı etkiler ve yetersiz etkinlik nedeniyle geliştirilmesi durdurulmuştur (Erbe ve ark., 2005; Liu ve ark., 2022). İlgi daha sonra aktif bölge dışındaki yüzeyleri de hedefleyen ligandlara kaymış; tiyazol bazlı ve karışık tip (mixed-type) inhibisyon sergileyen JTT-551, 0,22 μM'lik Ki değeri ve TCPTP'ye kıyasla 40 kattan fazla seçicilikle, diyetle indüklenen obez ve diyabetik fare modellerinde insülin- ve leptin-bağımlı parametreleri iyileştirmiştir (Fukuda ve ark., 2010; Ito, Fukuda, Sakata, Morinaga ve Ohta, 2014). Buna rağmen henüz onaylanmış bir PTP1B inhibitörü bulunmamakta, bu da katalitik ve allosterik bölgeleri hedefleyen yapı temelli ve hesaplamalı ilaç keşfi stratejilerini motive etmeye devam etmektedir.

Bu çalışmada, PTP1B kristal yapısını hedefleyen yeni inhibitör adaylarının farmakofor temelli sanal tarama stratejisiyle keşfedilmesi amaçlanmaktadır. PDB'den indirilen kristal yapı içerisindeki inhibitörün (OAI) etkileşimleri incelenerek farmakofor özellikleri belirlenmiş ve aynı özelliklere sahip bileşiklerden oluşan bir ilaç kütüphanesi hazırlanmıştır. OAI, Ertiprotafib ve JTT-551'in kontrol grubu olarak kullanıldığı farmakofor temelli sanal tarama ile bilinen inhibitörlere alternatif olabilecek yeni bileşikler belirlenmiştir. Bilinen ve yeni keşfedilen bileşiklerin ADME ve toksisite profilleri in siliko yöntemlerle karşılaştırmalı olarak değerlendirilmiştir. Elde edilen bulgular, ileride gerçekleştirilecek moleküler dinamik simülasyonlarıyla detaylandırılarak literatüre PTP1B inhibisyonuna yönelik yeni aday bileşikler kazandırılacaktır.

2. MATERYAL VE YÖNTEM

2.1.Protein Yapısının Hazırlanması ve Grid Box Dizaynı

Çalışmanın hedef proteini olan insan protein tirozin fosfataz 1B (PTP1B) enziminin üç boyutlu kristal yapısı, RCSB Protein Veri Bankası'ndan (PDB) temin edilmiştir (Berman ve ark., 2000). Hedef yapı olarak, enzimin katalitik bölgesine bağlanmış hâlde 6-(oksalilamino)-1H-indol-5-karboksilik asit (OAI) inhibitörünü içeren 1C83 kodlu yapı seçilmiş ve .pdb formatında indirilmiştir (Andersen ve ark., 2000). Bu yapının tercih edilmesinin başlıca nedenleri, çözünürlüğünün moleküler yerleştirme çalışmaları için yeterli düzeyde olması, katalitik cebin ligand bağlı (holo) konformasyonda çözülmüş olması ve kompleks hâlindeki OAI'nin fosfat taklidi niteliği taşıyarak bağlanma bölgesinin farmakofor gereksinimleri hakkında doğrudan yapısal bilgi sunmasıdır. İndirilen yapı, moleküler yerleştirme analizlerine hazırlanmak üzere UCSF Chimera yazılımının (sürüm 1.16) Dock Prep modülüne aktarılmıştır (Pettersen ve ark., 2004). Hazırlama aşamasında, kristalografik su molekülleri ve yapıda

bulunan diğer heteroatom gruplar yapıdan uzaklaştırılmış, eksik yan zincirler Dunbrack rotamer kütüphanesi kullanılarak tamamlanmış (Shapovalov ve Dunbrack, 2011), yapıya fizyolojik pH koşulları dikkate alınarak polar hidrojen atomları eklenmiş ve kısmi atomik yükler AMBER ff14SB kuvvet alanı parametreleri temel alınarak atanmıştır (Maier ve ark., 2015; Wang, Wang, Kollman ve Case, 2006). Hazırlanan reseptör yapısı, sonraki analizlerde kullanılmak üzere .pdbqt formatında kaydedilmiştir. Moleküler yerleştirme analizlerinin gerçekleştirileceği arama uzayı (grid box), kristal yapıda OAI'nin bağlanma profili ayrıntılı biçimde incelenerek ve ligandın temas kurduğu katalitik cep rezidüleri referans alınarak tanımlanmıştır. Bu doğrultuda grid box'ın merkez koordinatları x = 44,38, y = 13,77 ve z = 2,55 olarak belirlenmiş; kutu boyutları ise x, y ve z eksenlerinin her biri için 10 Å olacak şekilde 10 × 10 × 10 Å olarak ayarlanmıştır. Belirlenen bu arama uzayının, PTP1B'nin fosfat bağlayıcı P-ilmiğini (Ser216–Arg221), WPD-ilmiği üzerindeki katalitik Asp181 rezidüsünü ve cebin hidrofobik duvarını oluşturan Tyr46 rezidüsünü eksiksiz biçimde kapsadığı doğrulanmıştır.

2.2.Bilinen İnhibitörlerin Moleküler Kenetlenmesi

Moleküler yerleştirme protokolünün doğrulanması amacıyla kullanılan referans bileşiklerden Ertiprotafib ve JTT-551'in üç boyutlu yapıları ZINC15 (Sterling ve Irwin, 2015) ve PubChem (Kim ve ark., 2023) veritabanlarından, kristal yapıda PTP1B'ye bağlı hâlde bulunan OAI inhibitörünün yapısı ise RCSB Protein Veri Bankası'ndan (Berman ve ark., 2000) .sdf formatında indirilmiştir. İndirilen üç ligand, moleküler yerleştirme analizleri için PyRx sanal tarama platformuna (sürüm 0.8) aktarılmıştır (Dallakyan ve Olson, 2015). Yerleştirme işleminden önce, bileşiklerin enerjetik açıdan uygun konformasyonlar benimsemesini sağlamak amacıyla her bir ligand PyRx bünyesindeki Open Babel modülü kullanılarak enerji minimizasyonuna tabi tutulmuştur (O'Boyle ve ark., 2011). Minimizasyon işleminde Evrensel Kuvvet Alanı (Universal Force Field, UFF) ve eşlenik gradyan (conjugate gradient) algoritması tercih edilmiştir (Rappé, Casewit, Colwell, Goddard ve Skiff, 1992). Minimize edilen yapılar, döngüsel olmayan bağların dönebilir (rotatable) kabul edildiği koşullarda AutoDock ligandı formatına (.pdbqt) dönüştürülmüştür. Hazırlanan üç ligand, bir önceki aşamada tanımlanan grid box parametreleri (merkez: 44,38; 13,77; 2,55 — boyut: 10 × 10 × 10 Å) kullanılarak, PyRx arayüzünde çalıştırılan AutoDock Vina algoritması ile PTP1B'nin katalitik bölgesine dock edilmiştir (Trott ve Olson, 2010). Yerleştirme çalışmaları, yazılımın varsayılan kapsamlılık (exhaustiveness) değeri olan 8 ile gerçekleştirilmiş ve her bir ligand için dokuz adet bağlanma pozu üretilmiştir. Üretilen pozlar arasından en düşük bağlanma enerjisine sahip olan konformasyon, ilgili bileşiğin en olası bağlanma modu olarak kabul edilmiş ve sonraki analizlerde değerlendirilmiştir. OAI için elde edilen en iyi poz, aynı ligandın 1C83 kodlu kristal yapıdaki deneysel konformasyonu ile üst üste bindirilmiş ve iki poz arasındaki karesel ortalama sapma (RMSD) değeri hesaplanarak, tanımlanan grid box parametrelerinin ve yerleştirme protokolünün deneysel bağlanma modunu yeniden üretebilme başarısı sınanmıştır.

2.3.Farmakofor Modelinin Oluşturulması ve Farmakofor Temelli Bileşik Kütüphanesinin Hazırlanması

Doğrulanan bağlanma bölgesinin kimyasal ve geometrik gereksinimlerini sistematik biçimde tanımlamak amacıyla, yapı temelli farmakofor modelleme ve sanal tarama işlemleri Pharmit çevrim içi platformu kullanılarak gerçekleştirilmiştir (Sunseri ve Koes, 2016). Bu amaçla, PTP1B'nin katalitik cebine bağlı hâlde OAI inhibitörünü içeren 1C83 kodlu kompleks yapı, reseptör ve ligand bileşenleri ayrı ayrı olacak şekilde platforma yüklenmiştir. Pharmit, yüklenen kompleks üzerinden ligandın sahip olduğu farmakofor tanımlayıcılarını (hidrojen bağı alıcısı ve vericisi, hidrofobik bölge, aromatik halka, pozitif ve negatif iyonlaşabilir gruplar) otomatik olarak çıkarmış ve bunların üç boyutlu uzaydaki konumlarını hesaplamıştır. Otomatik olarak üretilen tanımlayıcılar arasından, OAI'nin PTP1B ile kurduğu etkileşimlerin analizine dayanılarak sorguda yer alacak özellikler seçilmiştir. Buna göre, ligandın karboksilat ve oksalilamino gruplarına karşılık gelen beş adet hidrojen bağı alıcısı ile indol çekirdeğini temsil eden bir adet hidrofobik özellik etkin hâle getirilmiş; birbiriyle örtüşen iki hidrojen bağı alıcısı ile iki negatif iyon tanımlayıcısı ise sorgu dışı bırakılmıştır. Negatif iyon tanımlayıcılarının kapatılması, taramanın yalnızca yüklü fosfat taklidi yapılarla sınırlanmasını engellemek ve kimyasal çeşitliliği daha yüksek bir aday havuzuna ulaşmak amacıyla tercih edilmiştir. Etkin hâle getirilen altı farmakofor özelliğinin her biri için tolerans yarıçapı, platformun varsayılan değeri olan 1,0 Å olarak korunmuştur. Oluşturulan bu altı noktalı farmakofor sorgusu ile ZINC Purchasable veritabanı (Sterling ve Irwin, 2015) taranmış ve tanımlanan geometrik düzeni karşılayan bileşikler, farmakofor uyum RMSD değerlerine göre artan sırada listelenmiştir. Tarama sonucunda elde edilen toplam 31.146 bileşik, sonraki

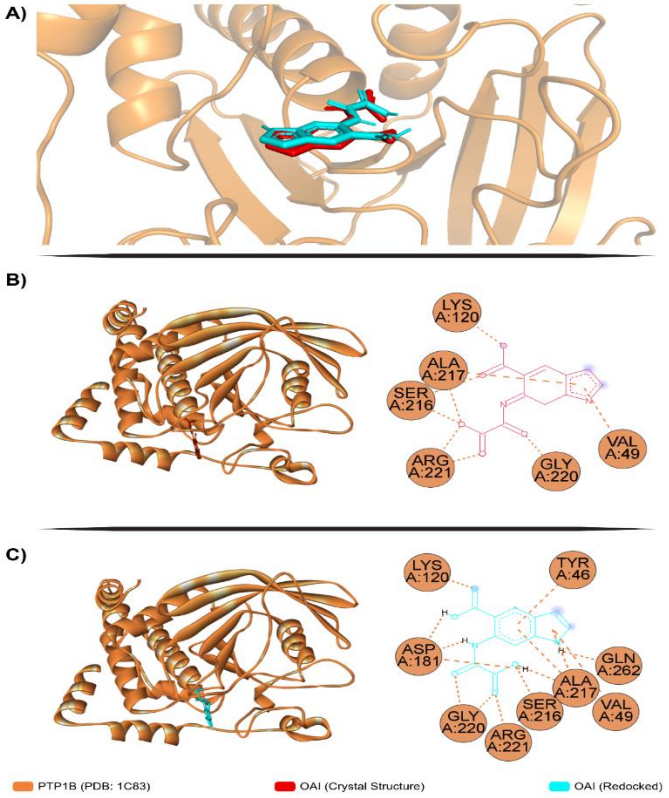
aşamada gerçekleştirilecek moleküler yerleştirme temelli sanal tarama çalışmasının bileşik kütüphanesini oluşturmak üzere .sdf formatında indirilmiştir.

2.4.Sanal İlaç Taraması

Farmakofor sorgusu aracılığıyla oluşturulan 31.146 bileşiklik kütüphane, PTP1B'nin katalitik bölgesine yönelik moleküler kenetlenme temelli sanal ilaç taramasına tabi tutulmuştur. Bu amaçla .sdf formatında indirilen bileşik kütüphanesinin tamamı, referans inhibitörler için uygulanan protokolle birebir aynı olacak şekilde PyRx sanal tarama platformuna (sürüm 0.8) aktarılmıştır (Dallakyan ve Olson, 2015). Kütüphanedeki her bir bileşik, kenetlenme işleminden önce platformun Open Babel tabanlı minimizasyon modülü kullanılarak enerji minimizasyonuna tabi tutulmuş (O'Boyle ve ark., 2011); minimizasyon işleminde Evrensel Kuvvet Alanı (UFF) ve eşlenik gradyan algoritması tercih edilmiştir (Rappé ve ark., 1992). Minimize edilen yapılar, döngüsel olmayan bağların dönebilir kabul edildiği koşullarda toplu biçimde AutoDock ligandı formatına (.pdbqt) dönüştürülmüştür. Hazırlanan kütüphane, protein hazırlama aşamasında OAI'nin bağlanma profili üzerinden tanımlanan ve yeniden yerleştirme analiziyle doğrulanan grid box parametreleri (merkez: 44,38; 13,77; 2,55 — boyut: 10 × 10 × 10 Å) değiştirilmeksizin kullanılarak, PyRx arayüzü üzerinden çalıştırılan AutoDock Vina algoritması ile hazırlanmış PTP1B reseptörüne dock edilmiştir (Trott ve Olson, 2010). Tarama, yazılımın varsayılan kapsamlılık (exhaustiveness) değeri olan 8 ile gerçekleştirilmiş ve her bir bileşik için en düşük bağlanma enerjisine sahip poz, ilgili molekülün en olası bağlanma modu olarak kaydedilmiştir. Tarama tamamlandıktan sonra bileşikler bağlanma enerjilerine göre artan sırada listelenmiş; elde edilen skorlar, aynı grid box kullanılarak kenetlenen referans inhibitörlerin (OAI, Ertiprotafib ve JTT-551) bağlanma enerjileri ile karşılaştırmalı olarak değerlendirilmiştir. Bu değerlendirme sonucunda -7 kcal/mol eşiğinin altında bağlanma enerjisi sergileyen bileşikler öne çıkarılmış ve bu adayların protein–ligand etkileşim profilleri, katalitik cebin kritik rezidüleriyle (Tyr46, Lys120, Asp181, Ser216, Ala217, Gly220 ve Arg221) kurdukları temaslar açısından ayrı ayrı incelenmiştir. Hem bağlanma enerjisi hem de etkileşim profili kriterlerini karşılayan 24 bileşik umut vaat edici aday olarak belirlenmiş, bunlar arasından en düşük bağlanma enerjisine sahip ve referans inhibitörlerin etkileşim ağını en kapsamlı biçimde tekrar eden ilk üç bileşik ileri analizler için seçilmiştir.

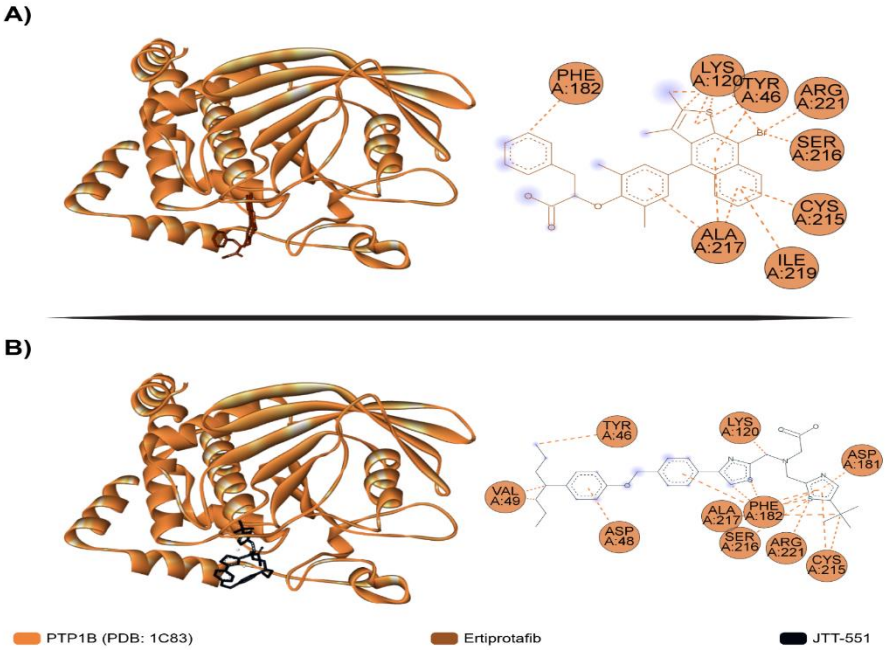
2.5.ADME ve Toksisite Profillerinin İn Siliko Değerlendirilmesi

Moleküler kenetlenme analizleri sonucunda öne çıkan üç aday bileşik (ZINC000106540127, ZINC000004879765 ve ZINC000006760732) ile çalışmada referans olarak kullanılan üç bilinen PTP1B inhibitörünün (OAI, Ertiprotafib ve JTT-551) ilaç benzeri özellikleri, farmakokinetik davranışları ve güvenlik profilleri in siliko yöntemlerle değerlendirilmiştir. Bu amaçla toplam altı bileşiğin kanonik SMILES gösterimleri ilgili veritabanlarından elde edilmiş ve analizler bu gösterimler üzerinden gerçekleştirilmiştir. Bileşiklerin absorpsiyon, dağılım, metabolizma ve atılım (ADME) profilleri SwissADME çevrim içi sunucusu kullanılarak öngörülmüştür (Daina, Michielin ve Zoete, 2017). Bu kapsamda her bir bileşik için molekül ağırlığı, kimyasal formül ve topolojik polar yüzey alanı (TPSA) gibi fizikokimyasal parametreler; konsensüs Log P*o/w* değeri üzerinden lipofilisite; ESOL modeli temelinde hesaplanan Log S değeri, çözünürlük miktarı ve çözünürlük sınıfı hesaplanmıştır. Farmakokinetik değerlendirmede, gastrointestinal emilim düzeyi ve kan–beyin bariyeri geçirgenliği BOILED-Egg modeli aracılığıyla tahmin edilmiş (Daina ve Zoete, 2016); ayrıca bileşiklerin P-glikoprotein substratı olup olmadıkları ile CYP1A2, CYP2C19, CYP2C9, CYP2D6 ve CYP3A4 izoformlarına yönelik inhibitör potansiyelleri öngörülmüştür. İlaç benzerliği, Lipinski (Lipinski, Lombardo, Dominy ve Feeney, 2001), Ghose, Veber (Veber ve ark., 2002), Egan ve Muegge filtreleri ile biyoyararlanım skoru üzerinden değerlendirilmiş; medisinal kimya parametreleri kapsamında ise PAINS uyarıları, öncü benzerliği (leadlikeness) ve sentetik erişilebilirlik skorları incelenmiştir. Bileşiklerin toksisite profilleri ProTox 3.0 çevrim içi sunucusu kullanılarak öngörülmüştür (Banerjee, Kemmler, Dunkel ve Preissner, 2024). Bu analizde her bir bileşik için öngörülen oral LD50 değeri (mg/kg) ve GHS sınıflandırmasına dayalı toksisite sınıfı hesaplanmış; organ toksisitesi kapsamında hepatotoksisite, nörotoksisite, nefrotoksisite, solunum toksisitesi ve kardiyotoksisite parametreleri değerlendirilmiştir. Ayrıca toksisite son noktaları başlığı altında karsinojenite, immünotoksisite, mutajenite, sitotoksisite, kan–beyin bariyeri geçişi, ekotoksisite, klinik toksisite ve beslenmeye bağlı toksisite öngörüleri elde edilmiştir. Her iki platformdan elde edilen tüm veriler, aday bileşikler ile referans inhibitörlerin karşılaştırmalı olarak değerlendirilebilmesi amacıyla tablolar hâlinde düzenlenmiştir.



3. BULGULAR VE TARTIŞMA

Moleküler yerleştirme protokolünün ve tanımlanan grid box parametrelerinin güvenilirliğini sınamak amacıyla, 1C83 kodlu kristal yapıda PTP1B'nin katalitik cebine bağlı hâlde bulunan OAI inhibitörü yapıdan uzaklaştırılmış ve aynı kutu koordinatları ile aynı yerleştirme ayarları kullanılarak proteine yeniden yerleştirilmiştir. Elde edilen en düşük bağlanma enerjisine sahip pozun kristal yapıdaki deneysel konformasyon ile üst üste bindirilmesi sonucunda, iki pozun katalitik cep içinde büyük ölçüde örtüştüğü gözlenmiştir (Şekil 1A). Ligandın bisiklik aromatik çekirdeği kristal yapıdaki yönelimini neredeyse birebir korumuş, sınırlı bir sapma yalnızca oksalilamino kolunun torsiyonel yerleşiminde dikkat çekmiştir. İki poz arasında hesaplanan RMSD değeri <2 Å olarak bulunmuştur. Yeniden yerleştirilen pozun bağlanma enerjisi ise -8,2 kcal/mol olarak hesaplanmıştır. Bu bulgular, oluşturulan grid box'ın hedef bağlanma bölgesini doğru biçimde kapsadığını ve seçilen yerleştirme algoritması ile parametrelerinin deneysel bağlanma modunu yeniden üretebilecek doğrulukta olduğunu göstermektedir. Konformasyonel örtüşmenin yanı sıra, kristal yapıdaki ve yeniden yerleştirilen OAI pozlarının protein–ligand etkileşim profilleri de karşılaştırmalı olarak incelenmiştir. Kristal yapıda OAI'nin karboksilat ve oksalilamino gruplarının Lys120, Ser216, Ala217, Gly220 ve Arg221 rezidüleri ile hidrojen bağı temelli bir ağ kurduğu, pirol halkası üzerinden ise Val49 ile ilave bir temas gerçekleştirdiği belirlenmiştir (Şekil 1B). Yeniden yerleştirilen pozda bu altı rezidünün tamamı korunmuş, bunlara ek olarak ligandın Tyr46, Asp181 ve Gln262 rezidüleri ile de etkileşime girdiği gözlenmiştir (Şekil 1C). Korunan temasların Ser216–Ala217–Gly220–Arg221 dizisi üzerinden fosfat bağlayıcı P-ilmiğine karşılık gelmesi, yeniden yerleştirilen pozun PTP1B katalitik cebindeki kanonik tanıma motifini eksiksiz biçimde yeniden ürettiğini ortaya koymaktadır. WPD-ilmiği üzerinde konumlanan Asp181, cebin hidrofobik duvarını oluşturan Tyr46 ve Q-ilmiği rezidüsü Gln262 ile kurulan ilave etkileşimler ise ligandın aktif bölgeye kristal yapıdaki hâline kıyasla daha kapsamlı biçimde gömüldüğüne işaret etmektedir. Hem konformasyonel hem de etkileşim düzeyinde sağlanan bu uyum, kurgulanan yerleştirme stratejisinin PTP1B katalitik bölgesi için geçerli olduğunu doğrulamış ve aynı protokolün bileşik kütüphanesinin sanal taranmasında güvenle kullanılabileceğini göstermiştir.

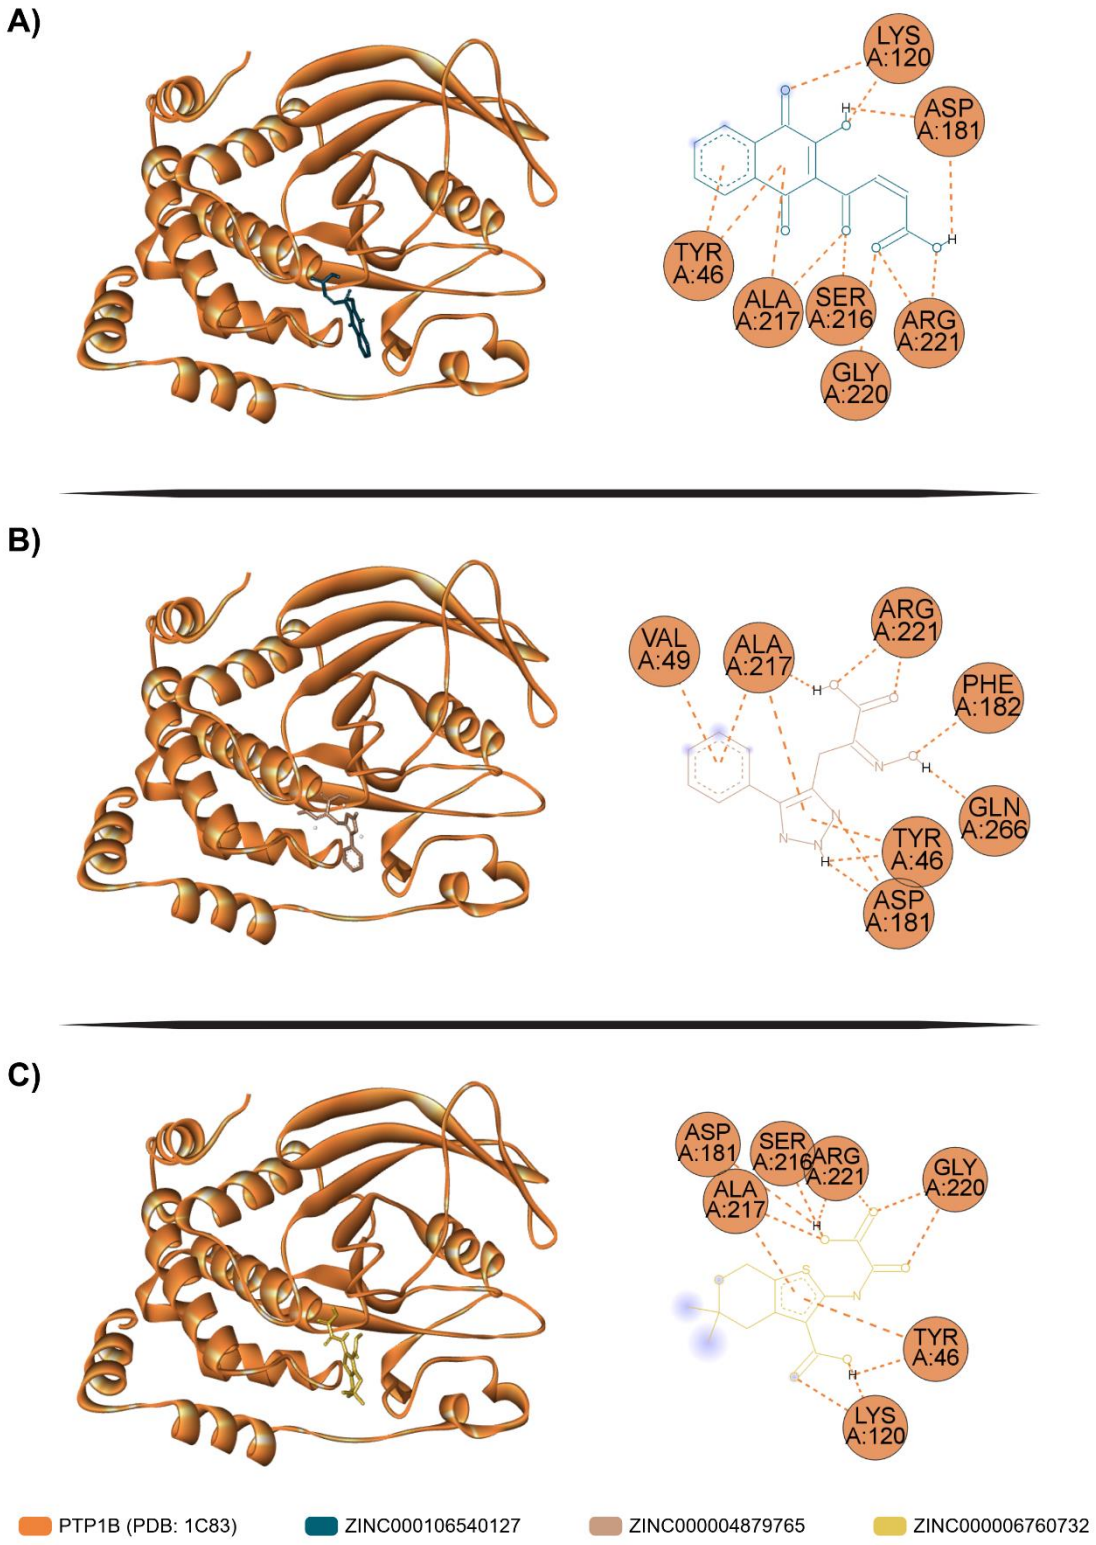


Yeniden yerleştirme ile doğrulanan protokolün bilinen etken moleküller üzerindeki performansını değerlendirmek ve sanal taramadan elde edilecek bileşikler için bir karşılaştırma ölçütü oluşturmak amacıyla, PTP1B'ye karşı geliştirilmiş ve klinik ile preklinik çalışmalara konu olmuş iki inhibitör, Ertiprotafib ve JTT-551, OAI için tanımlanan grid box koordinatları ve aynı yerleştirme parametreleri kullanılarak proteine dock edilmiştir. Ertiprotafib'in -10,4 kcal/mol bağlanma enerjisi ile katalitik cebe yerleştiği ve bromo-sübstitüe polisiklik aromatik çekirdeği üzerinden bağlanma bölgesinin merkezini işgal ettiği belirlenmiştir (Şekil 2A). Molekülün bu bölümünün Tyr46, Lys120, Cys215, Ser216, Ala217, Ile219 ve Arg221 rezidüleri ile temas kurduğu; dimetilfenil halkasının fosfat bağlayıcı P-ilmiği yüzeyine yaslanarak Ala217 ve Ile219 ile hidrofobik etkileşimler oluşturduğu gözlenmiştir. Brom atomunun Ser216 ve Arg221 rezidülerine yönelmiş konumu, ligandın P-ilmiği ile yapısal uyumunu desteklemektedir. Ligandın karşı ucunda yer alan fenil grubu ise WPD-ilmiği üzerindeki Phe182 ile aromatik istifleme etkileşimi kurarak molekülü cebin girişinde sabitlemiştir.

JTT-551 ise +15,4 kcal/mol gibi pozitif bir bağlanma enerjisi değeri vermiştir. Pozitif skor, ligandın tanımlanan arama uzayı içinde enerjetik açıdan elverişli bir yerleşim kuramadığına işaret etmektedir; bu durumun, 605,85 g/mol ağırlığındaki uzamış ve esnek molekülün OAI'ye göre kalibre edilmiş 10 × 10 × 10 Å'lık arama kutusuna sığmamasından kaynaklandığı değerlendirilmiştir. En iyi skorlu pozda molekülün tiyazol halkalarını ve karboksimetil grubunu taşıyan ucunun katalitik cebe yönelerek Lys120, Asp181, Phe182, Cys215, Ser216, Ala217 ve Arg221 rezidülerine, dallanmış alkil zincirlerini barındıran hidrofobik ucunun ise cebin girişindeki Tyr46, Asp48 ve Val49 rezidülerine komşu konumlandığı gözlenmiştir (Şekil 2B). Ancak pozitif bağlanma enerjisi nedeniyle bu poz enerjetik açıdan geçerli bir bağlanma modu olarak kabul edilmemiş ve JTT-551, sanal tarama sonuçlarının değerlendirilmesinde referans eşik olarak kullanılmamıştır. Bu sonuç, JTT-551'in literatürde karışık tip inhibisyon sergileyen ve aktif bölge dışındaki yüzeylerle de etkileşen bir molekül olarak tanımlanmasıyla uyumludur. Buna karşılık Ertiprotafib'in katalitik sistein Cys215 ve WPD-ilmiği rezidüsü Phe182 ile etkileşime girmesi, bu molekülün PTP1B'nin katalitik mekanizmasını doğrudan hedeflediğini ortaya koymaktadır. Ayrıca Tyr46, Lys120, Ser216, Ala217 ve Arg221 rezidülerinin hem yeniden yerleştirilen OAI pozunda hem de yapısal olarak OAI'den belirgin biçimde farklı olan Ertiprotafib'de ortak şekilde korunması, tanımlanan bağlanma bölgesinin PTP1B inhibisyonu için kritik olan farmakofor çekirdeğini kapsadığını göstermektedir.

Bu bulgular, kullanılan yerleştirme protokolünün katalitik cebe yönelen inhibitörleri tutarlı biçimde konumlandırabildiğini; buna karşılık aktif bölge dışına uzanan hacimli ligandlar için tanımlanan arama uzayının yetersiz kaldığını ortaya koymuştur. OAI ve Ertiprotafib için elde edilen bağlanma enerjileri, sanal tarama sonucunda öne çıkan bileşiklerin değerlendirilmesinde referans eşik olarak kullanılmıştır.

Şekil 1. PTP1B protein kristal yapısı (PDB: 1C83) içerisinde bulunan ve katalitik çekirdek ile etkileşime giren OAI inhibitörünün protein üzerindeki bağlanma profili; A) kristal yapıdaki ve yeniden kenetlenen OAI inhibitörlerinin protein içerisindeki konformasyonları, B) kristal yapıdaki OAI'nin protein ile sergilediği etkileşimler, C) yeniden kenetlenen OAI'nin protein ile sergilediği etkileşimler.



Şekil 2. Bilinen PTP1B inhibitörlerinin protein üzerindeki bağlanma profili; A) Ertiprotafib'in PTP1B katalitik çekirdeğindeki pozu, B) JTT-551'in PTP1B katalitik çekirdeğindeki pozu.

Doğrulanan bağlanma bölgesinin kimyasal gereksinimlerini sistematik biçimde tanımlamak amacıyla, OAI–PTP1B kompleksi Pharmit platformuna yüklenmiş ve ligandın katalitik cep içindeki etkileşim profilinden bir farmakofor modeli türetilmiştir. Yazılım tarafından otomatik olarak çıkarılan tanımlayıcılar arasından, ligandın karboksilat ve oksalilamino gruplarına ait beş hidrojen bağı alıcısı ile bisiklik aromatik çekirdeğe karşılık gelen bir hidrofobik özellik sorguda etkin hâle getirilmiş, her bir özellik için tolerans yarıçapı 1,0 Å olarak korunmuştur. Buna karşılık, iki negatif iyon tanımlayıcısı ve birbiriyle örtüşen iki hidrojen bağı alıcısı sorgu dışı bırakılmıştır; bu tercih, taramanın yalnızca yüklü fosfat taklidi bileşiklerle sınırlanmasını engellemek ve kimyasal çeşitliliği yüksek bir aday havuzuna ulaşmak amacıyla yapılmıştır. Oluşturulan altı noktalı farmakofor sorgusu ile ZINC Purchasable veritabanı taranmış ve tanımlanan geometrik düzeni karşılayan toplam 31.146 bileşik elde edilmiştir. Bileşikler farmakofor uyum RMSD değerlerine göre sıralandığında, en iyi uyumu gösteren adayın 0,229 Å RMSD değerine sahip olduğu belirlenmiş ve bu sonuç, sorgunun veritabanı içinde yüksek geometrik doğrulukla karşılanabildiğini ortaya koymuştur.

Farmakofor temelli olarak oluşturulan bu 31.146 bileşiklik kütüphanenin tamamı, OAI için tanımlanan ve yeniden yerleştirme ile doğrulanan grid box koordinatları kullanılarak PTP1B katalitik cebine kenetlenmiştir. Elde edilen bağlanma enerjileri ve protein–ligand etkileşim profilleri birlikte değerlendirildiğinde, -7 kcal/mol'den daha düşük bağlanma enerjisi sergileyen ve katalitik cebin kritik rezidüleriyle anlamlı temas kuran 24 bileşik umut vaat edici adaylar olarak öne çıkmıştır. Bu adaylar arasından, en düşük bağlanma enerjisine sahip olan ve aynı zamanda referans inhibitörlerin etkileşim ağını en kapsamlı biçimde tekrar eden üç bileşik — ZINC000106540127, ZINC000004879765 ve ZINC000006760732 — ileri analizler için seçilmiştir.

Seçilen bileşiklerin bağlanma modları ayrı ayrı incelendiğinde, üçünün de katalitik cebe yerleştiği ancak farklı kimyasal iskeletler üzerinden benzer bir tanıma ağı kurduğu görülmüştür. Naftokinon çekirdeği taşıyan ZINC000106540127, -8,2 kcal/mol bağlanma enerjisi ile cebe yerleşmiş; hidroksil ve karbonil grupları üzerinden Lys120 ve Asp181 ile, karboksil ucu üzerinden ise Ser216, Gly220 ve Arg221 rezidüleriyle hidrojen bağı kurmuş, aromatik çekirdeği Tyr46 ve Ala217 ile hidrofobik temas oluşturmuştur (Şekil 3A). Fenil-triazol iskeletine sahip ZINC000004879765, -8,0 kcal/mol bağlanma enerjisi göstermiş ve diğer iki bileşikten farklı bir yerleşim benimsemiştir; triazol halkası Tyr46 ve Asp181 ile etkileşirken, karboksilat grubu Ala217 ve Arg221 tarafından tutulmuş, fenil halkası Val49 ile hidrofobik temas kurmuş, imin köprüsü ise Phe182 ve Gln266 rezidülerine yönelmiştir (Şekil 3B). Tiyofen kaynaşmış bisiklik yapıdaki ZINC000006760732 ise -8,0 kcal/mol bağlanma enerjisi ile cebin en derin bölümüne yerleşmiş; amid ve karboksil grupları Asp181, Ser216, Ala217, Gly220 ve Arg221 ile yoğun bir hidrojen bağı ağı oluştururken, molekülün diğer ucundaki karboksil fonksiyonu Tyr46 ve Lys120 ile etkileşmiştir (Şekil 3C).

Üç bileşiğin etkileşim profilleri karşılaştırmalı olarak değerlendirildiğinde, Tyr46, Asp181, Ala217 ve Arg221 rezidülerinin tamamında ortak biçimde korunduğu belirlenmiştir. Bu dört rezidünün, katalitik cebin hidrofobik duvarını, WPD-ilmiğinin genel asit rezidüsünü ve fosfat bağlayıcı P-ilmiğinin iki temel bileşenini temsil etmesi, seçilen adayların PTP1B'nin katalitik mekanizmasını doğrudan hedefleyen bir bağlanma modu benimsediğine işaret etmektedir. Özellikle ZINC000106540127 ve ZINC000006760732 bileşiklerinin, birbirinden belirgin biçimde farklı kimyasal iskeletlere sahip olmalarına rağmen yeniden yerleştirilen OAI pozunun temas ettiği rezidülerin yedisini eksiksiz biçimde tekrar etmesi, farmakofor sorgusunun hedef bölgeye özgü tanıma gereksinimlerini başarıyla kodladığını göstermektedir. ZINC000004879765'in ise Phe182 ve Gln266 üzerinden cebin girişine doğru uzanarak, referans inhibitör JTT-551'in bağlanma yarığı boyunca uzanan yerleşimini andıran alternatif bir etkileşim ağı kurduğu gözlenmiştir. Bu bulgular, üç bileşiğin de bilinen PTP1B inhibitörlerinin temel farmakofor gereksinimlerini karşıladığını ve ileri değerlendirmeler için uygun adaylar olduğunu ortaya koymaktadır.

Şekil 3. Sanal tarama sonrası belirlenen 3 aday PTP1B inhibitörünün protein üzerindeki bağlanma profili; A) ZINC000106540127'nin PTP1B katalitik çekirdeğindeki pozu, B) ZINC000004879765'in PTP1B katalitik çekirdeğindeki pozu, C) ZINC000006760732'nin PTP1B katalitik çekirdeğindeki pozu.

Moleküler kenetlenme analizlerinin ardından, referans PTP1B inhibitörlerinin ilaç benzeri özelliklerini ve farmakokinetik davranışlarını öngörmek amacıyla OAI, Ertiprotafib ve JTT-551 bileşikleri SwissADME platformunda değerlendirilmiştir (Tablo 1). Fizikokimyasal parametreler incelendiğinde, üç molekül arasında belirgin bir boyut farkı dikkat çekmiştir: OAI 248,19 g/mol molekül ağırlığı ile düşük molekül ağırlıklı bir fragman niteliği taşırken, Ertiprotafib (559,51 g/mol) ve JTT-551 (605,85 g/mol) çok daha hacimli yapılar olarak öne çıkmıştır. Topolojik polar yüzey alanı değerleri sırasıyla 119,49 Å², 154,70 Å² ve 132,03 Å² olarak hesaplanmış olup, her üç bileşik de pasif membran geçişi için genel kabul gören 140 Å² eşiğine yakın veya bu eşiğin üzerinde konumlanmıştır. Lipofilisite açısından ise moleküller arasında çarpıcı bir ayrışma gözlenmiştir; OAI 0,08 gibi oldukça düşük bir Log P*o/w* değeri sergilerken, Ertiprotafib (7,79) ve JTT-551 (7,03) aşırı lipofilik karakter göstermiştir. Bu durum çözünürlük tahminlerine de doğrudan yansımış, OAI -0,02 Log S değeri ve $2{,}58\times10^{1}$ mg/ml çözünürlük ile "çözünür" sınıfında yer alırken, Ertiprotafib (-11,77; $9{,}50\times10^{-10}$ mg/ml) ve JTT-551 (-11,15; $4{,}25\times10^{-9}$ mg/ml) "çözünmez" sınıfına dahil edilmiştir.

Farmakokinetik öngörüler, fizikokimyasal profillerle uyumlu bir tablo ortaya koymuştur. OAI'nin gastrointestinal emiliminin yüksek olduğu tahmin edilirken, Ertiprotafib ve JTT-551 için düşük emilim öngörülmüştür. Üç bileşiğin de kan–beyin bariyerini geçemeyeceği belirlenmiş olup, bu bulgu periferik bir metabolik hedef olan PTP1B için istenen bir özellik olarak değerlendirilmiştir. P-glikoprotein substratlığı açısından OAI olumsuz sonuç verirken, Ertiprotafib ve JTT-551'in her ikisinin de bu taşıyıcı tarafından hücre dışına atılabileceği öngörülmüştür; bu durum, söz konusu moleküllerin hücre içi birikimini sınırlayabilecek ek bir dezavantaj oluşturmaktadır. Sitokrom P450 enzim inhibisyonu değerlendirildiğinde ise OAI'nin incelenen beş izoformun hiçbirini inhibe etmediği, Ertiprotafib'in yalnızca CYP2D6 üzerinde inhibitör etki gösterdiği, JTT-551'in ise CYP1A2, CYP2C19 ve CYP3A4 izoformlarını inhibe edebileceği tahmin edilmiştir. Bu sonuçlar, referans inhibitörlerin ilaç–ilaç etkileşimi riski taşıdığına işaret etmektedir.

İlaç benzerliği filtreleri incelendiğinde, OAI'nin Lipinski, Ghose, Veber, Egan ve Muegge kurallarının tamamını ihlalsiz biçimde karşıladığı belirlenmiştir. Buna karşılık Ertiprotafib yalnızca Veber kuralını karşılamış, diğer dört filtreden geçememiş; JTT-551 ise yalnızca Lipinski kuralını karşılayarak kalan dört filtrede başarısız olmuştur. Biyoyararlanım skorları sırasıyla 0,56, 0,85 ve 0,55 olarak hesaplanmıştır. Medisinal kimya değerlendirmesinde her üç bileşik için de PAINS uyarısı saptanmamış olması, moleküllerin deneysel tayinlerde yanlış pozitif sinyal üretme olasılığının düşük olduğunu göstermektedir; ancak hiçbiri öncü benzerliği (leadlikeness) ölçütünü karşılayamamıştır. Sentetik erişilebilirlik skorları OAI için 1,83, Ertiprotafib için 4,24 ve JTT-551 için 4,81 olarak hesaplanmış olup, yapısal karmaşıklık arttıkça sentez zorluğunun da belirgin biçimde yükseldiğini ortaya koymuştur. Bütün olarak değerlendirildiğinde, klinik ve preklinik aşamalara ulaşmış olan Ertiprotafib ve JTT-551'in aşırı lipofilik ve düşük çözünürlüklü yapılarının, ilaç benzerliği açısından ciddi sınırlamalar taşıdığı belirlenmiştir.

Tablo 1. Bilinen PTP1B inhibitörlerinin (OAI, Ertiprotafib ve JTT-551) farmakokinetik ve farmakodinamik özellilerini gösteren ADME profilleri.

	Leadlikeness	No	No	No
	Synthetic Accessibility	1.83	4.24	4.81

Referans inhibitörlerin güvenlik profillerini öngörmek amacıyla aynı bileşikler ProTox 3 platformunda analiz edilmiştir (Tablo 2). Öngörülen akut toksisite değerlendirmesinde OAI ve Ertiprotafib 5. toksisite sınıfında yer alırken, JTT-551 daha toksik olan 4. sınıfta konumlanmıştır. Bu sınıflandırma, hesaplanan oral LD50 değerleriyle doğrudan uyumludur; Ertiprotafib 3000 mg/kg ile en yüksek LD50 değerini sergilerken, OAI 2025 mg/kg ile onu izlemiş, JTT-551 ise 1000 mg/kg ile üç bileşik arasında akut toksisite açısından en riskli molekül olarak öne çıkmıştır.

Organ toksisitesi öngörüleri, üç bileşik arasında farklı hedef organlara yönelen ayrışık bir risk dağılımı ortaya koymuştur. OAI için nefrotoksisite, Ertiprotafib için hem hepatotoksisite hem de nefrotoksisite, JTT-551 için ise nörotoksisite pozitif olarak tahmin edilmiştir. Solunum toksisitesinin ise üç bileşiğin tamamında pozitif çıkması dikkat çekici bulunmuştur; bu ortak bulgu, incelenen moleküllerin paylaştığı yapısal özelliklerden kaynaklanabilecek genel bir risk unsuru olarak değerlendirilmiştir. Buna karşılık, hiçbir bileşik için kardiyotoksisite öngörülmemiştir.

Toksisite son noktaları incelendiğinde, karsinojenite, immünotoksisite, mutajenite ve sitotoksisite parametrelerinin üç bileşiğin tamamında negatif olarak tahmin edilmesi, moleküllerin genotoksik ve hücresel hasar potansiyelinin düşük olduğuna işaret etmiştir. Kan–beyin bariyeri geçişi açısından Ertiprotafib ve JTT-551 için pozitif sonuç elde edilmiş olması, SwissADME tahminleriyle çelişmekte olup bu farklılık, iki platformun farklı tahmin algoritmaları ve eğitim veri setleri kullanmasından kaynaklanmaktadır. Ekotoksisite yalnızca JTT-551 için pozitif çıkarken, klinik toksisite OAI ve JTT-551 için pozitif, Ertiprotafib için negatif olarak öngörülmüştür. Beslenmeye bağlı toksisite ise yalnızca Ertiprotafib'de saptanmıştır. Bu bulgular topluca değerlendirildiğinde, referans inhibitörlerin hiçbirinin toksisite açısından tamamen temiz bir profil sergilemediği ve her birinin farklı organ sistemlerine yönelik belirgin risk taşıdığı sonucuna ulaşılmıştır.

Tablo 2. Bilinen PTP1B inhibitörlerinin (OAI, Ertiprotafib ve JTT-551) toksisite profilleri.

Toxicity Profile				
Properties		**OAI**	**Ertiprotafib**	**JTT-551**

Sanal tarama sonucunda öne çıkan üç bileşiğin ilaç benzeri özellikleri, referans inhibitörlerle aynı protokol kullanılarak SwissADME platformunda değerlendirilmiştir (Tablo 3). Fizikokimyasal parametreler incelendiğinde, ZINC000106540127 (272,21 g/mol), ZINC000004879765 (246,22 g/mol) ve ZINC000006760732 (299,30 g/mol) bileşiklerinin tamamının düşük molekül ağırlığına sahip olduğu ve bu değerlerin OAI'nin molekül ağırlığına yakın bir aralıkta konumlandığı belirlenmiştir. Topolojik polar yüzey alanı değerleri sırasıyla 108,74 Å², 111,46 Å² ve 141,17 Å² olarak hesaplanmıştır. Lipofilisite açısından üç bileşik de 0,71–1,01 aralığında oldukça dar ve düşük Log P*o/w* değerleri sergilemiş, bu durum referans inhibitörler Ertiprotafib ve JTT-551'in aşırı lipofilik karakteriyle belirgin bir karşıtlık oluşturmuştur. Çözünürlük tahminleri de bu profili desteklemiş; Log S değerleri -1,74 ile -2,68 arasında değişen bileşiklerin üçü de "çözünür" sınıfında yer almış, hesaplanan çözünürlük değerleri $5{,}11\times10^{-1}$ ile $5{,}47\times10^{0}$ mg/ml aralığında bulunmuştur. Bu sonuç, referans inhibitörlerin pikogram düzeyindeki çözünürlük değerlerine kıyasla dokuz basamaklık bir iyileşmeye karşılık gelmektedir.

Farmakokinetik öngörüler, seçilen bileşiklerin emilim ve dağılım açısından elverişli bir profil sergilediğini ortaya koymuştur. Üç bileşiğin de gastrointestinal emiliminin yüksek olduğu tahmin

edilmiş, hiçbirinin kan–beyin bariyerini geçmeyeceği öngörülmüştür; periferik bir metabolik hedef olan PTP1B için bu kombinasyon istenen bir özellik olarak değerlendirilmiştir. Ayrıca hiçbir bileşiğin P-glikoprotein substratı olmadığı belirlenmiş, bu durum moleküllerin hücre dışına aktif taşınma yoluyla uzaklaştırılma riskinin düşük olduğuna işaret etmiştir. Sitokrom P450 enzim inhibisyonu değerlendirmesinde, ZINC000004879765 ve ZINC000006760732 bileşiklerinin incelenen beş izoformun hiçbirini inhibe etmediği; ZINC000106540127'nin ise yalnızca CYP1A2 izoformu üzerinde inhibitör etki gösterebileceği tahmin edilmiştir. Bu bulgular, seçilen adayların ilaç–ilaç etkileşimi potansiyelinin referans inhibitörlere kıyasla daha sınırlı olduğunu göstermektedir.

İlaç benzerliği filtreleri değerlendirildiğinde, ZINC000106540127 ve ZINC000004879765 bileşiklerinin Lipinski, Ghose, Veber, Egan ve Muegge kurallarının tamamını karşıladığı belirlenmiştir. ZINC000006760732 ise Lipinski ve Ghose kurallarından geçmiş, ancak yüksek polar yüzey alanı nedeniyle Veber, Egan ve Muegge filtrelerini karşılayamamıştır. Üç bileşiğin de biyoyararlanım skoru 0,56 olarak hesaplanmıştır. Medisinal kimya parametreleri incelendiğinde, ZINC000004879765 ve ZINC000006760732 için PAINS uyarısı saptanmazken, ZINC000106540127 bileşiğinde naftokinon çekirdeğinden kaynaklandığı düşünülen bir PAINS uyarısı belirlenmiştir; bu durum, söz konusu molekülün deneysel tayinlerde yanlış pozitif sinyal üretme olasılığını gündeme getirmektedir. Öncü benzerliği ölçütü ZINC000106540127 ve ZINC000006760732 tarafından karşılanmış, ZINC000004879765 bu filtreden geçememiştir. Sentetik erişilebilirlik skorları 2,82–3,24 aralığında hesaplanmış olup, referans inhibitörlerin 4,24 ve 4,81 değerlerine kıyasla daha kolay sentezlenebilir yapılar olduklarını ortaya koymuştur.

Tablo 3. Sanal tarama ile keşfedilen bileşiklerin farmakokinetik ve farmakodinamik özellilerini gösteren ADME profilleri.

ADME Profile				
Properties		**Best 3 Ligands**		
Physicochemical Properties	**ZINC ID**	**ZINC000106540127**	**ZINC000004879765**	**ZINC000006760732**

Seçilen üç bileşiğin güvenlik profilleri ProTox 3 platformunda analiz edilmiştir (Tablo 4). Öngörülen akut toksisite değerlendirmesinde üç bileşiğin de 4. toksisite sınıfında yer aldığı belirlenmiştir. Hesaplanan oral LD50 değerleri incelendiğinde, ZINC000006760732 1500 mg/kg ile en güvenli profili sergilerken, bunu 775 mg/kg ile ZINC000004879765 ve 487 mg/kg ile ZINC000106540127 izlemiştir. Bu değerler, referans inhibitörler OAI (2025 mg/kg) ve Ertiprotafib (3000 mg/kg) ile karşılaştırıldığında daha düşük düzeyde kalmakta, ancak JTT-551'in 1000 mg/kg değeriyle benzer bir aralığı paylaşmaktadır. Organ toksisitesi öngörüleri incelendiğinde, üç bileşiğin tamamı için nefrotoksisite ve solunum toksisitesi pozitif olarak tahmin edilmiştir. Hepatotoksisite yalnızca ZINC000004879765 için pozitif çıkmış, diğer iki bileşik bu parametrede negatif sonuç vermiştir. Buna karşılık nörotoksisite ve kardiyotoksisite üç bileşiğin hiçbirinde öngörülmemiştir; bu bulgu, özellikle referans inhibitör JTT-551 için saptanan nörotoksisite riski göz önüne alındığında olumlu bir ayrışma olarak değerlendirilmiştir. Toksisite son noktaları değerlendirildiğinde, immünotoksisite ve sitotoksisite parametrelerinin üç bileşiğin tamamında negatif olarak tahmin edilmesi, moleküllerin hücresel hasar ve bağışıklık sistemi üzerindeki olumsuz etki potansiyelinin düşük olduğuna işaret etmiştir. Ancak mutajenite ZINC000106540127 ve ZINC000004879765 bileşikleri için pozitif öngörülmüş, ZINC000006760732 ise bu parametrede negatif sonuç vermiştir. Karsinojenite yalnızca ZINC000004879765 için pozitif çıkmış olup, bu bileşiğin mutajenite ve hepatotoksisite öngörüleriyle birlikte değerlendirildiğinde üç aday arasında en kritik güvenlik uyarılarını taşıdığı belirlenmiştir. Kan–beyin bariyeri geçişi ZINC000106540127 ve ZINC000004879765 için pozitif tahmin edilmiş, bu sonuç SwissADME öngörüleriyle çelişmiştir; söz konusu farklılık, iki platformun farklı tahmin algoritmaları ve eğitim veri setleri kullanmasından kaynaklanmaktadır. Ekotoksisite ve beslenmeye bağlı toksisite üç bileşiğin hiçbirinde saptanmazken, klinik toksisite ZINC000106540127 ve ZINC000006760732 için pozitif öngörülmüştür. Bu bulgular topluca değerlendirildiğinde, ZINC000006760732 bileşiğinin en yüksek LD50 değeri, mutajenite ve karsinojenite açısından temiz profili ve sınırlı organ toksisitesi ile üç aday arasında en elverişli güvenlik profiline sahip molekül olarak öne çıktığı belirlenmiştir.

Tablo 4. Sanal tarama ile keşfedilen bileşiklerin toksisite profilleri.

	Nytritional Toxicity	No	No	No

Çalışmada elde edilen bağlanma enerjileri tek başına değerlendirildiğinde, en güçlü skorun -10,4 kcal/mol ile Ertiprotafib'e ait olduğu görülmektedir. Ancak bu molekül, aynı zamanda klinik geliştirme sürecinde başarısız olan tek bileşiktir; söz konusu çelişki, moleküler kenetlenme skorlarının tek başına ilaç adaylığı için yeterli bir ölçüt olmadığını açık biçimde ortaya koymaktadır. Ertiprotafib'in başarısızlığının altında yatan nedenler literatürde ayrıntılı biçimde incelenmiştir. Molekülün PTP1B'ye karşı IC_{50} değeri 1,6 µM düzeyinde kalırken IκB kinaz β (IKK-β) üzerindeki IC_{50} değeri 400 nM'dir; ayrıca bileşik PPARα ve PPARγ reseptörlerini, bu reseptörlerin bilinen agonistleriyle karşılaştırılabilir konsantrasyonlarda aktive etmektedir (Erbe ve ark., 2005; Shrestha, Bhattarai, Cho, Choi ve Cho, 2007). Bir başka deyişle molekül, asıl hedefinden çok daha güçlü biçimde hedef-dışı proteinleri etkilemektedir. Buna ek olarak NMR temelli yapısal çalışmalar, Ertiprotafib'in PTP1B'yi konsantrasyona bağımlı biçimde agregasyona sürüklediğini ve klinikte gözlenen yetersiz etkinlik ile yan etkilerin bu agregasyon eğiliminden kaynaklandığını göstermiştir (Kumar, Page ve Peti, 2020). Bu davranış, çalışmamızda Ertiprotafib için öngörülen fizikokimyasal profille birebir örtüşmektedir: 7,79'luk Log *P*o/w değeri, $9{,}50\times10^{-10}$ mg/ml'lik çözünürlük ve beş ilaç benzerliği filtresinden dördünün ihlali, tipik bir agregasyon

oluşturucu profiline işaret etmektedir. Aşırı lipofilik ve çözünmeyen bileşiklerin tayin koşullarında kolloidal agregatlar oluşturarak yalancı inhibisyon sinyali üretmesi, sanal tarama ve yüksek verimli tarama kaynaklı yalancı pozitiflerin başlıca mekanizmalarından biri olarak tanımlanmıştır (McGovern, Caselli, Grigorieff ve Shoichet, 2002). Dolayısıyla Ertiprotafib'in yüksek kenetlenme skoru, gerçek bir terapötik üstünlükten ziyade molekülün hacimli ve hidrofobik yapısının skorlama fonksiyonu tarafından ödüllendirilmesinin bir sonucu olarak yorumlanmalıdır.

Bununla birlikte keşfedilen bileşiklerin de sınırlamaları bulunmakta olup bunların tartışılmadan bırakılması yanıltıcı olacaktır. Her üç aday da karboksil grubu taşımakta ve fizyolojik pH'da anyonik karakter sergilemekte; 108,74–141,17 Å² aralığındaki topolojik polar yüzey alanı değerleri de bu durumu desteklemektedir. Bu nedenle, fosfotirozin taklidi inhibitörlerin klinik ilerlemesini sınırlandıran hücre geçirgenliği sorunu (Liu ve ark., 2022) azaltılmış olmakla birlikte tümüyle ortadan kaldırılmış değildir; SwissADME'nin yüksek gastrointestinal emilim öngörüsünün Caco-2 veya PAMPA gibi deneysel geçirgenlik tayinleriyle doğrulanması gerekmektedir (Daina ve ark., 2017). Aday-özgü riskler açısından ZINC000106540127 ayrıca ele alınmalıdır: bileşik, üç aday arasında en düşük bağlanma enerjisine sahip olmasına rağmen naftokinon çekirdeği nedeniyle PAINS uyarısı almış (Baell ve Holloway, 2010), en düşük LD50 değerini (487 mg/kg) sergilemiş ve mutajenite açısından pozitif öngörülmüştür. Kinon yapılarının redoks döngüsü ve tiyol reaktivitesi gösterebilmesi, katalitik sisteini (Cys215) redoks düzenlemesine açık olan PTP1B için özel bir risk oluşturmaktadır; bu rezidünün oksidasyonu, enzimi tersinir biçimde inaktive eden fizyolojik bir mekanizmadır (Salmeen ve ark., 2003). Dolayısıyla bu bileşik için öngörülen bağlanmanın hedefe özgü olmayan bir redoks etkileşiminden kaynaklanma olasılığı göz ardı edilmemelidir. Benzer şekilde ZINC000004879765'in karsinojenite, mutajenite ve hepatotoksisite öngörülerini bir arada taşıması, bu molekülü öncelik sırasında geriye düşürmektedir. Buna karşılık ZINC000006760732; PAINS uyarısı taşımaması, öncü benzerliği ölçütünü karşılaması, 1500 mg/kg ile en yüksek LD50 değerine sahip olması ve mutajenite ile karsinojenite açısından temiz bir profil sergilemesiyle ileri çalışmalar için en güçlü aday olarak öne çıkmaktadır. Son olarak, burada sunulan tüm bulguların hesaplamalı öngörülere dayandığı vurgulanmalıdır: kenetlenme skorlama fonksiyonlarının mutlak bağlanma serbest enerjisini tahmin etmedeki doğruluğu sınırlıdır ve poz sıralama başarısı ile afinite sıralama başarısı her zaman örtüşmemektedir (Trott ve Olson, 2010; Warren ve ark., 2006); ProTox öngörüleri ise yapısal benzerlik temelli modellere dayanmaktadır (Banerjee ve ark., 2024). Bu nedenle çalışmanın devamında planlanan moleküler dinamik simülasyonları ve MM-PBSA/MM-GBSA temelli serbest enerji hesaplamaları (Genheden ve Ryde, 2015), ardından da enzim inhibisyon tayinleriyle gerçekleştirilecek deneysel doğrulama, adayların gerçek potansiyelinin belirlenmesi açısından zorunludur.

4. SONUÇ VE ÖNERİLER

Bu çalışmada, tip 2 diyabet ve obezite tedavisinde doğrulanmış bir terapötik hedef olan PTP1B enziminin katalitik bölgesine yönelik yeni inhibitör adayları, farmakofor temelli sanal tarama yaklaşımıyla araştırılmıştır. Kristal yapıda bulunan OAI inhibitörünün yeniden kenetlenmesi, tanımlanan grid box parametrelerinin ve kenetlenme protokolünün deneysel bağlanma modunu doğru biçimde yeniden üretebildiğini göstermiş, böylece taramanın yapısal temeli güvence altına alınmıştır. OAI'nin katalitik cep içindeki etkileşim profilinden türetilen altı noktalı farmakofor sorgusu ile oluşturulan 31.146 bileşiklik kütüphanenin taranması sonucunda 24 umut vaat edici bileşik belirlenmiş, bunlar arasından üçü ileri değerlendirme için seçilmiştir. Seçilen adayların, birbirinden belirgin biçimde farklı kimyasal iskeletlere sahip olmalarına rağmen katalitik cebin kritik rezidüleriyle ortak bir tanıma ağı kurmaları, farmakofor sorgusunun hedefe özgü gereksinimleri başarıyla kodladığını ortaya koymuştur. Çalışmanın en dikkat çekici bulgusu ise ham bağlanma enerjileri ile ilaç adaylığı arasındaki uyumsuzluktur: en güçlü kenetlenme skorunu sergileyen referans bileşik Ertiprotafib, aynı zamanda klinik geliştirme sürecinde başarısız olan moleküldür ve bu çalışmada da en olumsuz fizikokimyasal profili sergilemiştir. Bağlanma enerjileri molekül büyüklüğüne göre normalize edildiğinde sıralama tersine dönmüş, keşfedilen üç aday ligand etkinliği açısından referans inhibitörlerin belirgin biçimde üzerinde konumlanmıştır. Düşük molekül ağırlığı, düşük lipofilisite, yüksek çözünürlük ve yüksek gastrointestinal emilim öngörüleriyle birlikte değerlendirildiğinde bu bileşikler, PTP1B inhibitörü geliştirme çabalarının önündeki klasik farmakokinetik darboğaza karşı somut bir alternatif sunmaktadır. Toksisite öngörüleri de dikkate alındığında ZINC000006760732, güvenlik ve ilaç benzerliği ölçütlerini birlikte karşılayan en dengeli aday olarak öne çıkmıştır.

Elde edilen sonuçların hesaplamalı öngörülere dayandığı ve deneysel doğrulama gerektirdiği göz önünde bulundurulduğunda, çalışmanın devamı için bir dizi öneri sıralanabilir. Öncelikle, seçilen adayların PTP1B ile oluşturduğu komplekslerin kararlılığı yeterli uzunlukta moleküler dinamik simülasyonlarıyla incelenmeli; RMSD, RMSF ve hidrojen bağı işgal oranı analizleriyle kenetlenme pozlarının zaman içinde korunup korunmadığı sınanmalı ve MM-PBSA/MM-GBSA temelli serbest enerji hesaplamalarıyla bağlanma afiniteleri yeniden değerlendirilmelidir. Yöntemsel açıdan, OAI'ye göre kalibre edilen arama uzayının hacimli ligandlar için yetersiz kaldığı görülmüş olup, aktif bölge dışına uzanan moleküllerin değerlendirilmesinde daha geniş bir arama kutusunun veya kör kenetlenme yaklaşımının tercih edilmesi uygun olacaktır. Deneysel aşamada, rekombinant PTP1B enzimi kullanılarak inhibisyon tayinlerinin gerçekleştirilmesi, IC_{50} ve Ki değerlerinin belirlenmesi ve inhibisyon kinetiğinin aydınlatılması öncelikli hedef olmalıdır. PTP ailesi içindeki yüksek yapısal korunmuşluk göz önüne alındığında, adayların başta TCPTP olmak üzere yakın homologlara karşı seçicilik profillerinin çıkarılması kritik önem taşımaktadır. Naftokinon çekirdeği taşıyan ZINC000106540127 için ise agregasyon ve redoks kaynaklı yalancı pozitifliği dışlamaya yönelik kontrol tayinlerinin uygulanması gerekmektedir. Bu basamakları başarıyla geçen adaylar, insülin reseptörü fosforilasyonu ve glukoz alımı gibi hücresel düzeydeki işlevsel tayinlerle sınanmalı; karboksil gruplarından kaynaklanan geçirgenlik sınırlamasının aşılması amacıyla ön-ilaç (prodrug) türevlendirmeleri dâhil olmak üzere yapısal optimizasyon stratejileri değerlendirilmelidir. Son olarak, bu çalışmada öne çıkan ancak ayrıntılı biçimde incelenmeyen diğer 21 bileşiğin de aynı iş akışıyla değerlendirilmesi, aday havuzunun genişletilmesine katkı sağlayacaktır.

HYBRID OPTIMIZATION-BASED PID DESIGN FOR AUTOMATIC VOLTAGE REGULATOR SYSTEMS

OTOMATİK GERİLİM REGÜLATÖRÜ SİSTEMLERİ İÇİN HİBRİT OPTİMİZASYON TABANLI PID TASARIMI

Abstract
Automatic voltage regulators (AVRs) play an essential role in power systems by regulating the terminal voltage of synchronous generators and maintaining a satisfactory voltage response under operating variations and disturbances. Although proportional–integral–derivative (PID) controllers are widely employed for AVR control because of their simple structure and practical applicability, appropriate tuning of their parameters remains important for achieving favorable stability characteristics together with satisfactory transient performance. In this study, a recently developed two-stage hybrid controller design method based on spectral abscissa and integral absolute error (IAE) optimization is utilized for the optimal tuning of a PID controller with a derivative filter for an AVR system. The conventional linearized AVR model consisting of amplifier, exciter, generator, and sensor subsystems is considered, and the proportional, integral, derivative, and derivative-filter parameters are treated as design variables. In the first stage, the controller parameters are determined by minimizing the spectral abscissa of the closed-loop system. Since the spectral abscissa corresponds to the largest real part of the closed-loop poles, its minimization aims to shift the dominant dynamics further into the left-half complex plane and thereby increase the exponential decay rate of the system. However, spectral abscissa minimization alone does not explicitly account for time-domain performance characteristics. Therefore, in the second stage, the IAE of the terminal-voltage error is minimized to improve the transient performance. The second-stage optimization is initialized using the controller obtained from the first stage and is performed subject to a spectral abscissa constraint, allowing improvement of the voltage response while limiting deterioration of the favorable stability characteristics achieved previously. The effectiveness of the proposed design framework will be investigated through numerical simulations, with emphasis on the closed-loop spectral properties and transient terminal-voltage response.
Keywords: Automatic voltage regulator, PID controller, spectral abscissa, integral absolute error, optimization

Özet
Otomatik gerilim regülatörleri (AVR'ler), senkron generatörlerin terminal gerilimini düzenleyerek ve işletme koşullarındaki değişimler ile bozucular altında uygun bir gerilim cevabı sağlayarak güç sistemlerinde önemli bir rol oynamaktadır. Oransal–integral–türev (PID) denetleyiciler, basit yapıları ve pratik uygulanabilirlikleri nedeniyle AVR kontrolünde yaygın olarak kullanılmakla birlikte, elverişli kararlılık özellikleri ile tatmin edici geçici rejim performansının birlikte elde edilebilmesi için denetleyici parametrelerinin uygun şekilde ayarlanması önemini korumaktadır. Bu çalışmada, AVR sistemi için türev filtresine sahip bir PID denetleyicinin optimal olarak ayarlanmasında, spektral apsis ve integral mutlak hata (IAE) optimizasyonuna dayalı yakın zamanda geliştirilmiş iki aşamalı hibrit bir denetleyici tasarım yöntemi kullanılmaktadır. Yükselteç, uyartım sistemi, generatör ve sensör alt sistemlerinden oluşan klasik doğrusallaştırılmış AVR modeli ele alınmakta; oransal, integral, türev ve türev filtresi parametreleri tasarım değişkenleri olarak kabul edilmektedir. İlk aşamada, denetleyici parametreleri kapalı çevrim sisteminin spektral apsisi minimize edilerek belirlenmektedir. Spektral apsis, kapalı çevrim kutuplarının en büyük reel kısmına karşılık geldiğinden, bu büyüklüğün minimize edilmesi baskın dinamiklerin karmaşık düzlemin sol yarı bölgesinde daha sola taşınmasını ve böylece sistemin üstel sönüm hızının artırılmasını amaçlamaktadır. Bununla birlikte, yalnızca spektral apsisin minimize edilmesi zaman alanındaki performans özelliklerini doğrudan dikkate almamaktadır. Bu nedenle ikinci aşamada, geçici rejim performansını iyileştirmek amacıyla terminal gerilimi hatasının IAE değeri minimize edilmektedir. İkinci aşamadaki optimizasyon, ilk aşamadan elde edilen denetleyici kullanılarak başlatılmakta ve spektral apsis kısıtı altında gerçekleştirilmektedir.

Böylece, daha önce elde edilen elverişli kararlılık özelliklerindeki bozulma sınırlandırılırken gerilim cevabının iyileştirilmesi hedeflenmektedir. Önerilen tasarım çerçevesinin etkinliği, kapalı çevrim spektral özellikleri ve terminal geriliminin geçici rejim cevabı üzerine odaklanılarak sayısal benzetimler aracılığıyla incelenecektir.

Anahtar kelimeler: Otomatik gerilim regülatörü, PID denetleyici, spektral apsis, integral mutlak hata, optimizasyon

ANN BASED GENERALIZED PREDICTIVE CONTROL OF A DC MOTOR UNDER DISTURBANCE

BOZUCU ETKİ ALTINDAKİ BİR DC MOTORUN YAPAY SİNİR AĞI TEMELLİ GENELLEŞTİRİLMİŞ ÖNGÖRÜLÜ KONTROLÜ

Asst. Prof. Erdem DİLMEN
Pamukkale University, Technology Faculty, Mechatronics Engineering Department,
Denizli, Türkiye
ORCİD: ID/000-0003-3092-0927

Abstract
This paper presents an Artificial Neural Network (ANN)-based Generalized Predictive Control (GPC) scheme for a DC motor under external disturbance. To account for system disturbance, ANN model is utilized to capture the time-varying dynamics online, predicting the future system outputs directly from observed input-output data. Using these predictions, the GPC algorithm calculates control inputs over a predefined future horizon and applies the signal corresponding to the current time step. The ANN parameters are tuned using gradient descent with an adaptive learning rate (ALR), which guarantees model convergence while ensuring controller stability. The proposed approach demonstrates robust control performance in simulation under disturbance condition. It outperforms a standard PID controller in comparative evaluation. This study cen be generalized to GPC of any particular type of DC motor as well.
Keywords: Artificial neura network, Generalized predictive control, DC motor, PID control

Özet
Bu çalışma, harici bozucu etki altındaki bir DC motor için Yapay Sinir Ağı (artificial neural network-ANN) tabanlı bir Genelleştirilmiş Öngörülü Kontrol (generalized predictive control-GPC) yöntemi sunmaktadır. Sistemdeki bozucu etkiyi hesaba katmak amacıyla YSA modeli, zamana bağlı olarak değişen dinamikleri çevrimiçi (online) olarak yakalamak ve gözlemlenen girdi-çıktı verilerinden doğrudan gelecekteki sistem çıktılarını tahmin etmek için kullanılmaktadır. GPC algoritması, bu tahminleri kullanarak önceden belirlenmiş bir gelecek ufku boyunca kontrol girdilerini hesaplar ve mevcut zaman adımına karşılık gelen sinyali sisteme uygular. ANN parametreleri, modelin yakınsamasını ve kontrolün kararlılığını garanti eden uyarlamalı öğrenme adımlı gradyan inişi (gradient descent) yöntemi kullanılarak güncellenmektedir. Önerilen yaklaşım, bozucu etki koşulu altındaki benzetimde gürbüz bir kontrol performansı sergilemektedir. Karşılaştırmalı değerlendirmelerde standart bir PID denetleyiciden daha iyi performana sahip olduğu gözlemlenmiştir. Bu çalışma, herhangi bir özel DC motor tipinin GPC kontrolüne de genelleştirilebilir.

ÖZET
Portland çimentosunun artan küresel üretimi ve CO_2 emisyonlarını azaltmaya yönelik acil ihtiyaç, katkılı çimento üretiminin artırılmasını zorunlu kılmıştır. Son dönemde, kalsine killer bu talebi karşılamak adına oldukça umut verici malzemeler olarak öne çıkmıştır. Bu çalışma, kalsine marn katkılı çimento içeren mikro-betonların yüksek sıcaklığa maruz kaldıklarında sergiledikleri davranışı incelemektedir. %0, %10, %20 ve %30 ikame oranlarında kalsine marn içeren katkılı çimentolar kullanılarak dört farklı karışım hazırlanmıştır. Mikro-betonların özgül ağırlık, su emme, eğilme ve basınç dayanımı değerleri belirlenmiştir. Mikro-betonların yüksek sıcaklık altındaki performansını değerlendirmek amacıyla 300 °C, 600 °C ve 800 °C sıcaklık seviyeleri kullanılmıştır. Deneysel sonuçlar, alternatif bir puzolan olan kalsine marn katkılı çimentolarla üretilen mikro-betonların eğilme ve basınç dayanımlarının, %20 ikame oranına kadar artış gösterdiğini ortaya koymuştur. Ayrıca, puzolanik özellikli kalsine marn kullanımının, yüksek sıcaklık koşullarında mikro-betonların yangın direnci üzerinde olumlu bir etkiye sahip olduğu tespit edilmiştir. Mikro-beton numuneleri için sağlanan bu olumlu sonuçların yanı sıra, söz konusu katkılı çimentolarla çimento içeriğinin en aza indirilmesi, son derece sürdürülebilir ve uygun maliyetli bir üretim süreci sağlamaktadır.
Anahtar kelimeler: Kalsine Marn, Katkılı Çimento, Puzolan, Yangın Dayanımı.

ABSTRACT
The increasing global production of Portland cement and the urgent need to mitigate CO_2 emissions have necessitated a rise in the production of blended cements. Recently, calcined clays have emerged as highly promising materials to address this demand. This study investigates the behavior of micro-concretes containing calcined marl blended cement under high-temperature exposure. Four different mixtures were prepared using blended cements containing calcined marl at replacement levels of 0%, 10%, 20%, and 30%. The density, water absorption, and flexural-compressive strength values of the micro-concretes were determined. To evaluate the performance of the micro-concretes under high temperatures, exposure levels of 300 °C, 600 °C, and 800 °C were utilized. The experimental results revealed that the flexural and compressive strengths of the micro-concretes produced with blended cements containing the alternative pozzolan, calcined marl, increased up to a replacement level of 20%. Furthermore, it was determined that the incorporation of calcined marl had a positive effect on the fire resistance of the micro-concretes under elevated temperature conditions. Besides these positive outcomes for micro-concrete specimens, minimizing cement content with these blended cements ensures a highly sustainable and cost-effective production process.
Keywords: Calcined Marl, Blended Cement, Pozzolan, Fire Resistance.

GİRİŞ
Küresel enerji güvenliğine yönelik endişeleri gidermenin hızlı, maliyetsiz ve uygulanabilir yolu enerji tasarrufudur. Kalkınmakta olan ülkeler, enerji ithalatını azaltmak için enerji yoğun sektörlerde tasarruf politikalarına yönelmektedir. Bu sektörlerin başında gelen inşaat alanında ise üretimi maliyetli ve yüksek emisyonlu olan çimentoya bağımlılık kritik bir sorundur. Çimentoya alternatif olarak doğal puzolan kullanımı, üretimi ekonomik ve çevreci hale getirirken betonun performansını da artırmaktadır (Erdal, 2026). Türkiye, zengin doğal puzolan rezervleriyle sürdürülebilir çimento ve beton üretimi açısından oldukça yüksek bir potansiyeline sahiptir (Beniz, 2022).

Puzolanlar**,** en genel anlamıyla kendi başlarına bağlayıcılık özelliği taşımayan, ancak çimento inceliğinde öğütüldüklerinde içerdikleri reaktif silis ve alümin bileşenleri sayesinde, çimento hidratasyonu ürünü olan kalsiyum hidroksit ($Ca(OH)_2$) ile reaksiyona girerek hidrolik bağlayıcılık karakteristiği kazanan malzemelerdir. Bu puzolanik reaksiyon, matris yapısını yoğunlaştırarak nihai ürünün dayanım ve dayanıklılığını artırır. Literatürde killerin 600 °C – 900 °C sıcaklık aralığında kalsine edildiklerinde yüksek puzolanik aktivite gösterdikleri de bilinmektedir (Daştan, 2005).
Puzolan kullanılarak üzetilen betonların dayanım ve dayanıklılıklarındaki artışa bağlı olarak onların yangın dayanımlarının da iyileştiği literatürden bilinmektedir (Karaca ve ark., 1997). Puzolanlar, betonun yüksek sıcaklık altındaki performansını iki temel mekanizmayla iyileştirir: İlki, termal olarak kararsız olan ve 400 °C üzerinde bozunarak hacimsel çatlaklara yol açan kalsiyum hidroksit ($Ca(OH)_2$) kristallerini puzolanik reaksiyonla tüketerek daha kararlı C-S-H jellerine dönüştürmesidir. İkincisi ise, oluşturduğu yoğun ve hidrolik yapısı sayesinde ısı iletimini yavaşlatması ve mikrodolgu etkisiyle yüksek sıcaklık kaynaklı termal gerilmeleri sönümlemesidir (Lublóy ve ark., 2017).
Literatürde yaygın olarak kullanılan mineral katkıların yüksek sıcaklık performansları incelendiğinde; silis dumanının oluşturduğu aşırı yoğun matris yapısı sebebiyle yangın anında yüksek iç buhar basıncına maruz kalarak patlamalı çatlamalara yol açabildiği bilinmektedir. Uçucu kül ise küresel tanecik yapısıyla ısıl gerilmeleri sönümlemede başarılı olsa da erken yaş reaksiyon hızı düşüktür. Buna karşın, metakaolin gibi kalsine killer hem yüksek puzolanik aktivitesi sayesinde ($Ca(OH)_2$)'i hızla tüketmekte hem de yüksek sıcaklıklarda termal olarak daha kararlı amorf alüminosilikat fazları oluşturmaktadır. Bu durum, kalsine killeri yüksek yangın dayanımı hedeflenen beton tasarımlarında diğer puzolanlara göre daha avantajlı bir konuma getirmektedir (Kushnir ve ark., 2021; Lublóy ve ark., 2017; Morsy ve ark., 2007).
Doğal marn, kil ve kalkeri bir arada bulunduran, kalkerin %30-50 ve kilin %50-70 oranlarında karışımından oluşan, bir kayaç türüdür. Genellikle %30 kil ve %70 kalker içeren marnlar çimento yapımında kullanılırlar (Özer, 2024). Geleneksel çimento klinkerinin kalsinasyon sıcaklığına kıyasla çok daha düşük bir seviyede (yaklaşık 800 °C) kalsine edilerek puzolanik aktivite kazanan doğal marnlar, aynı zamanda kolay öğütülebilir yapıları sayesinde katkılı çimento üretimi için de yüksek bir potansiyel sunmaktadır. Literatürde kalsine marnların çimento ve beton endüstrisinde kullanılabilirliği üzerine oldukça yeni ve güncel çalışmalar mevcut olmakla birlikte, bu malzemelerin yüksek sıcaklık ve yangın dayanımı üzerindeki performansını inceleyen kapsamlı bir çalışma henüz bulunmamaktadır.

Betonun yüksek sıcaklıklara maruz kaldığında uğradığı mekanik performans kayıpları dikkate alındığında, bu çalışmanın temel hedefleri şunlardır:

- Yerel ve doğal puzolan rezervlerinin aktif hale getirilmesiyle sürdürülebilir malzeme çeşitliliğinin artırılması,
- Katkılı çimento ve beton endüstrisinde doğal puzolan kullanımının yaygınlaştırılmasına katkı sağlanması,
- Yangın riski yüksek yapılar için betonun termal direncini artıracak tasarım optimizasyonlarının gerçekleştirilmesi,
- Nihai olarak, literatürde kullanımı oldukça yeni ve umut vadeden kalsine marn katkılı çimento ile üretilen betonların yangın dayanımlarının iyileştirilmesidir.

MATERYAL VE YÖNTEM

Bu çalışmada hedeflenen yüksek yangın dayanımlı beton tasarımlarının optimize edilmesi amacıyla deneysel bir yöntem izlenmiştir. Yöntem, yerel kaynaklardan elde edilen doğal marnların kalsinasyon sürecinin ardından kalsine marn katkılı çimento üretimi, mikro-beton numunelerinin hazırlanması, yangın deneyleri ve performans değerlendirme aşamalarını içermektedir. Üretilen mikro-betonların farklı sıcaklıklar altındaki mekanik davranışları standart test yöntemleri ile incelenmiştir. Çalışmada kullanılan malzemelere ilişkin bazı tanımlamalar aşağıda verilmektedir.
Mikro-betonların imalatında kullanılacak katkılı çimento üretimlerinde Portland çimentosu ile ağırlıkça %10, 20 ve 30 oranlarında yerdeğiştirme malzemesi olarak optimum sıcaklıkta (800 °C) kalsine edilmiş Sinop ili, Erfelek ilçesinden elde edilen kalsine marn kullanılmıştır. Portland çimentosu (CEM 42.5 R) Ünye Çimento A.Ş'den temin edilmiştir. Doğal marnın puzolanik aktivitesini belirlemek için TS 25' in önerdiği mekanik deney yöntemi kullanılmış ve standardın aktivite minimum sınır değeri (>4MPa) ölçütünü 8.10MPa olarak sağlamıştır. Optimum kalsinasyon sıcaklığında (800 ^{0}C) kalsine edilen marnın

puzolonik aktivite değeri, mekanik deney yöntemi olan kireç-doğal puzolan karışımlı numunelerin 7 günlük basınç dayanımları ile belirlenmiştir. Çalışmada kullanılan Portland çimentosu ve doğal marn ait bazı özellikler Tablo 1-2 de verilmektedir.

Tablo 1. Portland Çimentosuna ait Bazı Özellikler

Kimyasal	**(%)**	**Fiziksel ve Mekanik Özellikler**			
SiO_2	19.53	Özgül ağırlık, (g/cm^3)	3.12		
Al_2O_3	5.33	Priz başı, (saat)	2.50		
Fe_2O_3	3.56	Priz sonu, (saat)	4.15		
CaO	62.26	Hacim genleşmesi, (mm)	2.00		
MgO	0.99	Blaine (cm^2/g)	3210		
SO_3	3.02	Basınç dayanımları	2 gün	7 gün	28 gün
Kızdırma kaybı	3.06	(MPa)	32.30	44.60	53.00

Tablo 2. Doğal Marnın Bazı Özellikleri

Kimyasal	**(%)**	**Fiziksel özellikler**	
SiO_2	56.63	Özgül ağırlık, (g/cm^3)	2.70
Al_2O_3	12.34	Blaine (cm^2/g)	4630
Fe_2O_3	7.46	Puzolanik aktivite (MPa)	
CaO	12.91	7 günlük basınç	8.10
MgO	2.83	dayanımı	

Mikro-betonların üretiminde kullanılan ince agrega, Gümüşhane ili, Torul ilçesinden temin edilmiştir. Mikro-betonların üretiminde kullanılan agregalara ilşkin granülometrik dağılım Tablo 3' de ve agregaların doygun kuru yüzeyli (DKY), kuru ve görünür özgül ağırlıkları ve su emme değerleri ise TS EN 1097-6' e uygun olarak belirlenerek Tablo 4' de verilmektedir. Çimento inceliğinin altında öğütülen kalsine marnın inceliğinin oluşturduğu karışımların kıvam sabitliğini sağlamak ve daha homojen dağılımlı çimento taneleri elde etmek için polikarboksilat eter tipi hiperakışkanlaştırıcı kullanılmıştır. Akışkanlaştırıcının özgül ağırlığı 1.05 gr/cm^3 tür. Mikro-betonların karışım suyu bileşeni olarak içme suyu kalitesinde Ordu ili, Altınordu ilçesine ait şebeke suyu kullanılmıştır. Mikro-betonlara ait bileşen miktarları Tablo 5' de verilmektedir.

Tablo 3. Agregaların Granülometrik Dağılımı

Granülometrik Dağılım					
Elek çapı (mm)	4-2	2-1	1-0,5	0,5-0,25	0,25-0
(%)	40	20	15	15	10

Tablo 4. Agregaların Özgül Ağırlıkları ve Su Emme Değerleri

Elek çapı (mm)	**Özgül Ağırlıklar (g/cm^3)**			**Su Emme (%)**
	Kuru	**DKY**	**Görünür**	
(4 - 1)	2.69	2.70	2.71	0.33
(1 - 0)	2.63	2.67	2.72	1.18

Tablo 5. Mikro-Betonlara Ait Bileşen Miktarları

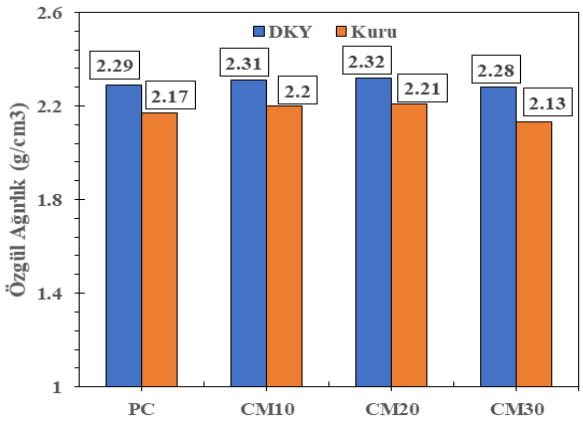
Bileşenler (kg/m^3)	**PC**	**CM10**	**CM20**	**CM30**
Portland Çimentosu	450	405	360	315
Kalsine Marn	-	45	90	135
Su	225	225	225	225
Toplam Agrega	1350	1350	1350	1350
Akışkanlaştırıcı	3.60	4.50	4.73	4.95

Karışımlara taze haldeyken mini-çökme deneyi yapılmıştır. Ardından 40 x 40 x 160 mm boyutlarındaki prizmatik kalıplara yerleştirilmiştir. 24 saat sonunda kalıplarından çıkarılan numuneler etiketlenerek kür tankına yerleştirilmiştir. Mikro-betonlara ait bazı görünümler Şekil 1' de verilmektedir.

Şekil 1. Mikro-betonların üretim sonrası görünümleri

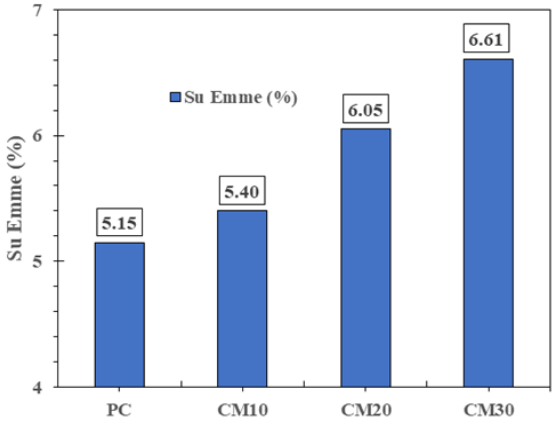
Deney numunelerine yangın etkisini belirlemek amacı ile yangın deneyleri başlamadan önce 40x40x160 mm'lik prizmatik numuneler önce 24 saat süresince 70 ^{o}C' de etüvde bırakılarak sabit numune ağırlıkları elde edilmiştir. Daha sonra numuneler fırın sıcaklık artış hızı 5-10 ^{o}C/dk olan yüksek sıcaklık fırınına yerleştirilmişlerdir. Deney programındaki sıcaklıklar (300 ^{0}C – 600 ^{0}C – 800 ^{0}C) elde edildikten sonra numuneler fırında 1 saat süresince bırakılmışlardır. Yangın deneyleri tamamlandıktan sonra yüksek sıcaklık fırınından çıkarılan mikro-beton numuneler havada ve suda soğutma koşulları ile soğutulmuşlardır. Her iki koşul altındaki tüm numuneler oda sıcaklığına getirilmişlerdir. Mikro-beton numunelerin TS EN 196-1' e uygun eğilme-basınç dayanımları tespit edilmiştir. Elde edilen deney sonuçları, yangın etkisinde bırakılmayan geleneksel numunelerin sonuçları ile karşılaştırılmıştır. Yangın etkisinde kalmış mikro-beton numunelerinin genel görünümleri Şekil 2' de verilmektedir.

Şekil 2. Yangın Etkisinde Kalmış Mikro-Beton Numuneler ve Yüksek Sıcaklık Fırını



ARAŞTIRMA BULGULARI VE TARTIŞMA

Kalsine marn içeren katkılı çimentolar kullanılarak üretilen mikro-beton numuneler üzerinde yukarıda açıklanan yöntemlere göre gerçekleştirilen deneylerden elde edilen bulgular ve tartışmalar aşağıda verilmektedir.



Mini Çökme, Özgül Ağırlık ve Su Emme

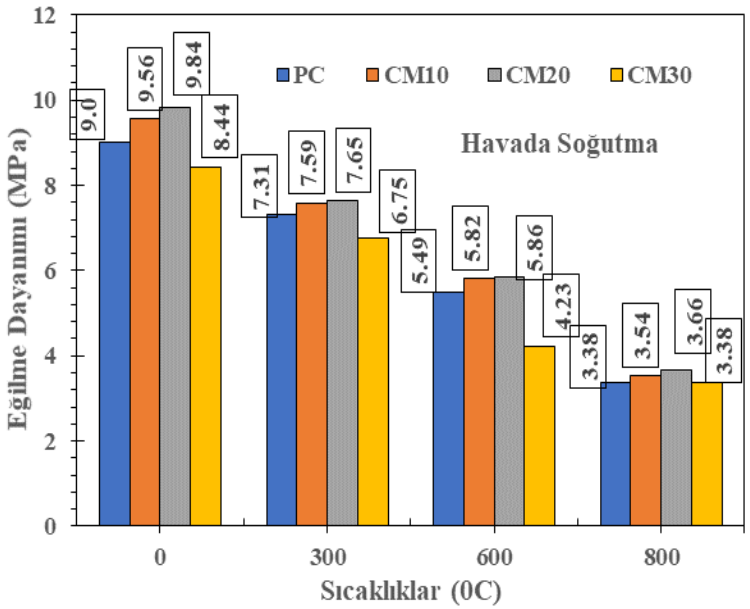
Mini slump deneyi sonucunda mikro-betonların her bir karışımı için çökme değerleri yaklaşık olarak 20-30 mm civarında tespit edilmiştir. Mikro-betonların doygun kuru yüzeyli (DKY) ve kuru özgül ağırlıkları ve su emme değerleri Şekil 3-4' de verilmektedir.

Mikro-betonların (CM10, CM20, CM30) DKY özgül ağırlıkları, Portland çimentosununkine göre sırasıyla %0,9, %1,3 artmış, %0,4 azalmış ve kuru özgül ağırlıkları ise sırasıyla %1,4, %1,8 artmış, %1,9 azalmıştır. Bu değişimler, mikro-betonları oluşturan bileşenlerin özgül ağırlıklarına bağlı olarak meydana gelmektedir. Mikro-betonların (CM10, CM20, CM30) su emme değerleri, Portland çimentosununkine göre sırasıyla %4,9, %17,5, %28,3 artmıştır. Bu değişimler ise, kalsine marnın inceliğinin Portland çimentosununkine göre daha yüksek olması ile ilişkilidir.

Şekil 3. DKY- Kuru Özgül Ağırlıklar

Şekil 4. Su Emme Değerleri

Katkılı Çimentoların Fiziksel Özellikleri

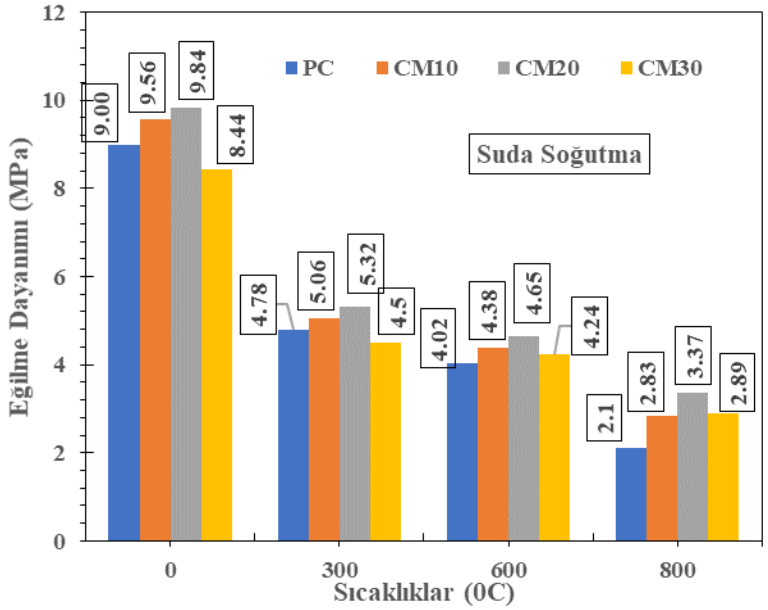


Çalışmada kullanılan kalsine marn içeren katkılı çimentoların bazı fiziksel özellikleri Tablo 6' da verilmektedir. Katkılı çimentoların Blaine incelikleri, Portland çimentosununkine göre sırasıyla %2,96, %10,28, %12,46 artmıştır. Diğer bir değişle, katkılı çimentoların incelikleri marnın inceliğine bağlı olarak azalmıştır. Katkılı çimentoların özgül ağırlıkları, Portland çimentosununkine göre sırasıyla %5,8, %9,9, %10,6 azalmıştır. Katkılı çimentoların özgül ağırlıklarındaki azalma marnın özgül ağırlığındaki azalmaya bağlıdır.

Tablo 6. Katkılı Çimentoların Fiziksel Özellikleri

Fiziksel özellikler	**PC**	**CM10**	**CM20**	**CM30**
Blaine inceliği (cm^2/g)	3210	3305	3540	3610
Özgül Ağırlık (g/cm^3)	3.12	2.95	2.84	2.82

Eğilme - Basınç Dayanımları Bulguları

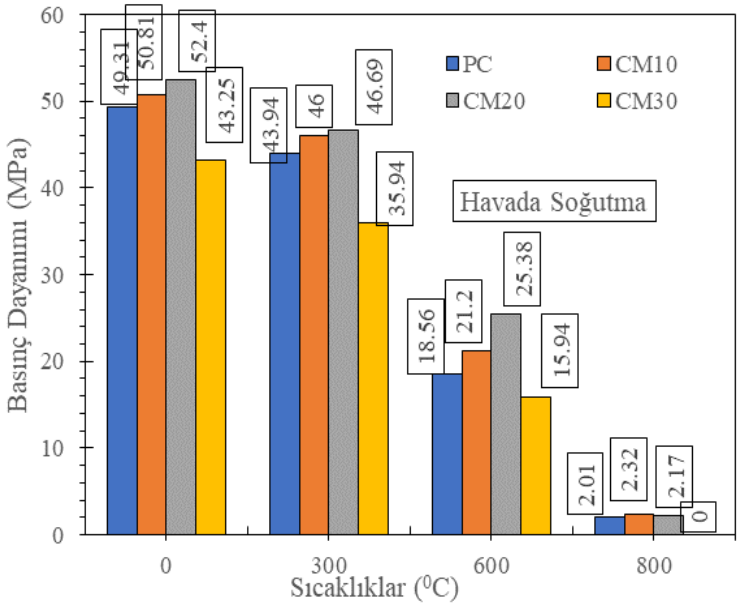


Çalışmada üretilen mikro-betonların yangın deneyleri sonrası eğilme-basınç dayanımları havada ve suda soğutma koşullarına göre sırasıyla Şekil 5-8'de verilmektedir.

Şekil 5. Mikro-Betonların Yangın Deneyleri Sonrası Eğilme Dayanımları (Havada Soğutma)

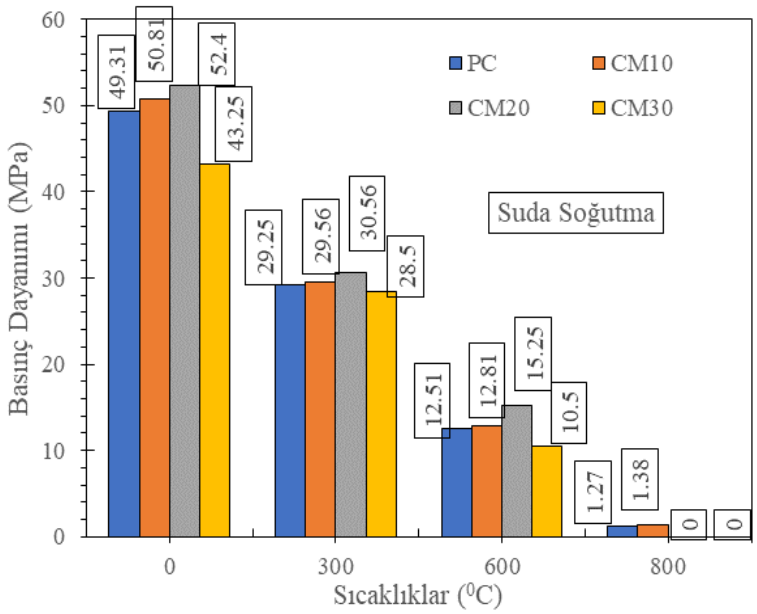
Yüksek sıcaklık maruziyeti sonrasında havada soğutulan numunelerin eğilme dayanımı gelişimleri incelendiğinde; 300 °C ve 600 °C maruziyetlerinde CM10 ve CM20 serilerinin, referans (PC)

numunesine kıyasla daha yüksek bir termal direnç gösterdiği ve eğilme dayanımlarını daha iyi koruduğu görülmüştür. Bu durum, literatür ile uyumlu olarak (Ibrahim ve ark., 2012), kalsine marnın puzolanik aktivitesi sonucu oluşan yoğun C-S-H matrisinin ve serbest kireç tüketiminin olumlu bir sonucudur. Ancak 800 °C sıcaklığa ulaşıldığında tüm serilerde keskin bir dayanım kaybı kaydedilmiştir. Literatürle uyumlu olan bu düşüş (Lublóy ve ark., 2017); 700 °C'nin üzerindeki sıcaklıklarda betona asıl dayanımı veren C-S-H jellerinin kimyasal olarak tamamen dehidrasyona uğrayarak bozunması ve agregadaki kuvars faz dönüşümü kaynaklı mikroskobik çatlak ilerlemeleri ile açıklanmaktadır. Buna rağmen, 800 °C'de bile CM10 (3.54 MPa) ve CM20 (3.66 MPa) serilerinin geleneksel PC serisine (3.38 MPa) göre daha yüksek dayanım sergilemesi, optimize edilmiş kalsine marn ikamesinin yüksek sıcaklıklarda yapısal bütünlüğü korumadaki başarısını ortaya koymaktadır.



Şekil 6. Mikro-Betonların Yangın Deneyleri Sonrası Eğilme Dayanımları (Suda Soğutma)

Yüksek sıcaklık maruziyeti sonrasında suda soğutulan numunelerin eğilme dayanımı gelişimleri incelendiğinde; kalsine marn ikamesinin matris performansına olan pozitif etkisi bu zorlu koşul altında da net bir şekilde gözlenmiştir. 300 °C, 600 °C ve 800 °C sıcaklık aşamalarının tamamında, %10 (CM10) ve %20 (CM20) kalsine marn içeren seriler, referans (PC) numunesine kıyasla daha yüksek eğilme dayanımı değerleri sergilemiştir. Özellikle 800 °C gibi ileri seviye ısıl yıkımın gerçekleştiği aşamada, PC numunesinin eğilme dayanımı 2.10 MPa'ya düşerken, CM20 numunesi 3.37 MPa ile en yüksek direnci ortaya koymuştur. Suda soğutma koşullarında puzolanik katkının sağladığı bu avantaj, literatürde belirtildiği gibi (Kushnir ve ark., 2021), kalsine killerin matris içindeki serbest kalsiyum hidroksiti ($Ca(OH)_2$) önceden tüketmesiyle doğrudan ilişkilidir. Nitekim yüksek sıcaklıkta kalsiyum oksite dönüşen serbest kireç, suyla ani temas anında hızla dehidrasyona uğrayarak şiddetli hacimsel genleşmelere ve içsel patlamalara yol açmaktadır. CM10 ve CM20 serilerinde bu zayıf faz puzolanik reaksiyonla ortadan kaldırıldığı için, matris ani su temasını daha az hasarla atlatmıştır. Ancak ikame oranının %30'a yükseltilmesi (CM30), bağlayıcı faz dengesini olumsuz etkilediğinden tüm sıcaklıklarda dayanımın tekrar düşmesine neden olmuştur.



Soğutma yöntemlerinin betonun termal davranışı üzerindeki etkisini belirlemek amacıyla, havada soğutma ve suda soğutma rejimleri karşılaştırmalı olarak analiz edilmiştir. Elde edilen tüm veriler, soğutma tekniğinin eğilme dayanımı üzerinde belirleyici bir rol oynadığını ve suda soğutulan numunelerin havada soğutulanlarınkine kıyasla çok daha radikal güç kayıplarına uğradığını göstermektedir. Örneğin 300 °C' de havada soğutulan PC numunesi 7.31 MPa değerini koruyabilirken, suda soğutulduğunda bu değer 4.78 MPa'ya gerilemiştir. Benzer bir eğilim kalsine marn katkılı serilerde de görülmüş, ancak kalsine marn içeren numuneler bu kaybı sınırlamada daha başarılı olmuştur. Suda soğutmanın yarattığı bu ek yıkım, ani sıcaklık düşüşünün beton matrisinde şiddetli termal gerilmeler (termal şok) üretmesinden kaynaklanmaktadır. Eğilme dayanımı, yapısı gereği mikroskobik çatlak

ilerlemelerine karşı basınç dayanımından çok daha hassastır. Dolayısıyla, suda ani soğutma esnasında matris ile agrega arayüzünde oluşan mikro çatlak şebekeleri, suda soğutulan serilerin eğilme dayanımını doğrudan ve keskin bir biçimde aşağı çekmiştir.

Şekil 7. Mikro-Betonların Yangın Deneyleri Sonrası Basınç Dayanımları (Havada Soğutma)

Yüksek sıcaklık maruziyeti sonrası havada soğutulan numunelerin basınç dayanımı sonuçları incelendiğinde; kalsine marn katkısının betonun eksenel yük taşıma kapasitesi üzerindeki olumlu etkisi, oda sıcaklığından itibaren kendini göstermiştir. Oda sıcaklığında en yüksek basınç dayanımı 52.40 MPa ile %20 kalsine marn içeren CM20 serisinde elde edilmiş; bu seriyi 50.81 MPa ile CM10 takip ederek şreferans (PC) numunesini (49.31 MPa) geride bırakmıştır. Bu durum, literatürde de belirtildiği gibi (Danner ve ark., 2018), kalsine marnın yüksek puzolanik aktivitesi sayesinde mikro boşlukları doldurarak daha yoğun bir jel (C-S-H) yapısı meydana getirmesinin doğrudan bir sonucudur.
Sıcaklık artışıyla birlikte tüm serilerde dayanım kayıpları gözlenmiş, ancak bu kayıpların oranları seriler arasında farklılık göstermiştir. 300 °C ve özellikle 600 °C maruziyetlerinde CM10 ve CM20 serileri, referans PC numunesine kıyasla dikkate değer ölçüde daha iyi korumuştur. 600 °C'de PC numunesinin dayanımı %62.3 oranında radikal bir kayıpla 18.56 MPa'ya gerilerken; CM20 serisi 25.38 MPa, CM10 serisi ise 21.20 MPa değerlerini korumayı başarmıştır. Bu kritik aşamadaki puzolanik avantaj, literatürde de belirtildiği gibi (Danner ve ark., 2018), kalsine killerin matristeki termal olarak kararsız kalsiyum hidroksit ($Ca(OH)_2$) kristallerini erkenden tüketerek yapıyı 400°C – 600°C aralığındaki dehidrasyon çatlaklarından koruması ile açıklanmaktadır. Ancak 800 °C sınırına ulaşıldığında, tüm serilerin basınç dayanımlarında tam bir yapısal çöküş (yıkım) kaydedilmiştir. Bu aşamada PC, CM10 ve CM20 serileri 2.01 ile 2.32 MPa arasında değişen sembolik dayanım değerlerine düşerken, %30 kalsine marn içeren CM30 serisi yük taşıma kabiliyetini tamamen kaybederek 0 MPa değerini almıştır. Literatürle tam bir uyum gösteren bu ileri düzey yıkım (Lublóy ve ark., 2017); 700 °C'nin üzerinde ana bağlayıcı faz olan C-S-H jellerinin kimyasal yapısının tamamen bozulması, matris bütünlüğünün yok olması ve agreganın gösterdiği şiddetli termal genleşmeler sonucu oluşan makro çatlaklar ile ilişkilendirilmektedir. Ayrıca aşırı puzolan ikamesine sahip CM30 serisinin yüksek sıcaklık kararsızlığı, optimize edilmemiş yüksek mineral katkı oranlarının ısıl gerilmeler altındaki kırılganlığını net bir şekilde ortaya koymaktadır.

Şekil 8. Mikro-Betonların Yangın Deneyleri Sonrası Basınç Dayanımları (Suda Soğutma)

Yüksek sıcaklık maruziyeti sonrasında suda soğutulan numunelerin basınç dayanımı performansları incelendiğinde; ani sıcaklık düşüşünün (termal şok) yarattığı yapısal tahribat tüm serilerde kendisini net bir şekilde göstermiştir. 300 °C ve 600 °C sıcaklık aşamalarında, %10 (CM10) ve %20 (CM20) kalsine marn içeren seriler, referans (PC) numunesine kıyasla daha yüksek bir eksenel yük taşıma kapasitesi sergilemiştir. Özellikle 600 °C maruziyetinde PC numunesinin dayanımı 12.51 MPa'ya gerilerken, CM20 serisi 15.25 MPa değerini koruyarak en yüksek kararlılığı ortaya koymuştur. Bu sıcaklık kademelerindeki puzolanik avantaj, literatürde (Barauskas, 2020), kalsine killerin boşluk doldurma (mikrodolgu) kabiliyeti ve matrisi daha kompakt hale getiren ikincil C-S-H jelleri sayesinde, su temasıyla oluşan ani çekme gerilmelerine karşı iç yapının daha dirençli kalabilmesi ile açıklanmaktadır. Ancak 800 °C sınırına gelindiğinde, suda soğutma rejiminin yıkıcı etkisi numune matrisini tamamen işlevsiz hale getirmiştir. Bu ileri sıcaklık derecesinde PC (1.27 MPa) ve CM10 (1.38 MPa) serileri sembolik dayanım değerlerinde kalırken; %20 ve %30 kalsine marn içeren CM20 ve CM30 serileri yük taşıma kabiliyetlerini tamamen yitirerek 0 MPa değerini almıştır. Literatür verileriyle desteklenen bu durum (Morsy ve ark., 2007); 800 °C'de zaten kimyasal ve fiziksel olarak bağlayıcılığını bütünüyle yitirmiş, C-S-H yapısı bozunmuş olan beton matrisinin, suyla temas ettiği anda şiddetli bir buhar basıncına ve ısıl gerilmeye maruz kalmasından kaynaklanmaktadır. Yüksek mineral katkı oranına sahip CM20 ve CM30 serilerinin daha gevrek yapısı, bu ani faz değişimi ve termal şok altında mikro/makro çatlakların hızla ilerlemesine yol açarak numunelerin bütünlüğünü tamamen kaybetmesine neden olmuştur.

Soğutma rejimlerinin basınç dayanımı üzerindeki etkileri karşılaştırıldığında; suda soğutma tekniğinin, havada soğutmaya kıyasla tüm serilerde ve sıcaklıklarda çok daha agresif bir dayanım kaybına yol açtığı görülmüştür. Örneğin, 300 °C'de havada soğutulan PC numunesi 43.94 MPa değerini koruyabilirken, suda soğutulduğunda bu değer %33.4'lük bir düşüşle 29.25 MPa'ya gerilemiştir. Benzer şekilde 600 °C'de havada 25.38 MPa basınç dayanımı gösteren CM20 serisi, suda soğutulduğunda 15.25 MPa değerine düşmüştür. Basınç dayanımındaki bu radikal farklar; sıcak beton matrisinin suyla ani teması esnasında oluşan yüksek termal gradyanların, betonun dış kabuğu ile çekirdeği arasında şiddetli gerilmelere (termal şok) neden olmasından kaynaklanmaktadır. Bu fiziksel gerilmeler, matris genelinde yoğun bir mikro çatlak ağı oluşturarak eksenel yük taşıma kapasitesini doğrudan aşağı çekmiştir.

SONUÇLAR

Bu çalışma kapsamında, yerel ve doğal puzolan rezervlerinin aktif hale getirilerek çimento-beton sektöründe kullanımının yaygınlaştırılması ve kalsine marn katkılı betonların yüksek sıcaklık/yangın

altındaki performans sınırlarının belirlenmesi hedeflenmiştir. Deneysel veriler ve yapılan analizler doğrultusunda aşağıdaki temel sonuçlara ulaşılmıştır:

- Kalsine marnın çimento matrisindeki optimum kullanım oranının %20 (CM20) olduğu belirlenmiştir. Hem oda sıcaklığında (52.40 MPa basınç ve 9.84 MPa eğilme dayanımları olarak) hem de yüksek sıcaklık maruziyetlerinde en yüksek mekanik performans CM20 serisinde elde edilmiştir.
- 300 °C ve özellikle 600 °C sıcaklık kademelerinde CM10 ve CM20 serileri, referans (PC) numunesine göre daha yüksek bir kararlılık sergilemiştir. Bu durum, kalsine marnın puzolanik reaksiyonu sayesinde termal olarak kararsız olan ($Ca(OH)_2$) (kalsiyum hidroksit) kristallerini erkenden tüketmesi ve daha kararlı ikincil C-S-H jelleri oluşturması ile açıklanmaktadır.
- Suda soğutma (termal şok) rejimi, havada soğutmaya kıyasla tüm serilerde ve sıcaklıklarda çok daha agresif mekanik performans kayıplarına yol açmıştır. Su temasıyla oluşan ani termal gradyanlar, matris genelinde yoğun bir mikro çatlak dağılımının meydana geldiği düşünülmektedir.
- Yangın söndürme senaryolarını simüle eden 800 °C suda soğutma koşullarında; şahit (PC) numunesi 2.10 MPa eğilme dayanımına gerilerken, CM20 serisi 3.37 MPa değerini koruyarak referansa göre yaklaşık %60 daha yüksek performans göstermiş ve kalsine marnın çatlak ilerlemesini sınırlandırmadaki başarısını kanıtlamıştır.
- 800 °C sınırına ulaşıldığında, beton matrisindeki ana bağlayıcı faz olan C-S-H jellerinin kimyasal olarak tamamen dehidrasyona uğraması ve agreganın kuvars faz dönüşümü kaynaklı genleşmesi nedeniyle genel bir yapısal çöküş kaydedilmiştir. Bu ileri sıcaklık aşamasında, yüksek kalsine marn katkı oranına sahip CM30 serisi her iki soğutma rejiminde de, CM20 serisi ise suda soğutma altında yük taşıma kabiliyetini tamamen yitirerek "0" MPa basınç dayanımı değeri almıştır.
- Geleneksel çimento klinkerine kıyasla oldukça düşük bir sıcaklıkta (yaklaşık 800 °C) kalsine edilerek puzolanik aktivite kazanan yerel kalsine marnın beton endüstrisinde kullanımı; hem küresel enerji tasarrufu ve düşük karbon emisyonu hedeflerini desteklemekte hem de yüksek yangın riskli yapılar için optimize edilmiş, ekonomik ve güvenli bir tasarım alternatifi sunmaktadır.

Abstract
High turbine inlet temperatures place severe thermal demands on gas-turbine hot-section components, while the compressor bleed required for cooling reduces cycle performance. This study develops a physics-constrained reduced-order model (ROM) for a tafoni-inspired graded gyroid triply periodic minimal surface (TPMS) cooling concept. The aim is to provide a conservative, literature-benchmarked screening method for use before high-fidelity CFD or experiments. A thresholded Gray-Scott morphology is quantified using void fraction, local feature width, and interface density, and these descriptors are mapped to gyroid cell size and level-set threshold. The sheet-gyroid solid and its two complementary fluid labyrinths are defined explicitly so that porosity, specific area, hydraulic diameter, mass flow, and energy balances remain consistent. Internal heat transfer is represented with an experimental sheet-gyroid Nusselt correlation, while low-Reynolds-number pressure-loss trends are compared with published TPMS data. Film extraction is treated with explicit coolant mass and enthalpy conservation, and film and porous-effusion modes are not used together on the same surface element.
The ROM was checked against analytical solutions. The axial energy solution shows first-order convergence, the normalized energy residual remains at machine precision, and the expected limits are recovered for vanishing and large coolant flow, vanishing TBC resistance, and zero blowing. Sensitivity and uncertainty analyses identify gyroid cell size, gas-side heat-transfer coefficient, and the transferred gyroid Nusselt level as the main sources of local response variation; together they account for approximately 91% of the variance in the screening surrogate. The nominal coolant requirement of 0.768 g/s increases to about 1.12 g/s at the 95th percentile when independent ±20% epistemic uncertainties are imposed. In a controlled load-matched graded-gyroid surrogate with approximately equal porosity and internal area, the model hotspot falls by 18.7 K and the required coolant decreases by 8.3% relative to a uniform gyroid. This controlled comparison is interpreted as a ROM mechanism test. The operating state is classified as mixed heat-transfer/coolant-capacity controlled, with hydraulic loss providing an additional design constraint.
Keywords: tafoni; gyroid; TPMS; turbine-blade cooling; reduced-order model; transpiration cooling; film cooling; robust design; biomimetic design.

1. Introduction
Higher turbine inlet temperatures can increase specific work and cycle efficiency, but they also raise the thermal load on metallic hot-section components. Current cooling systems therefore combine internal convection, thermal-barrier coatings (TBCs), film cooling, double-wall cooling, and increasingly complex additively manufactured internal geometries [1-5]. Because the coolant is usually extracted from the compressor, additional cooling increases the aerodynamic and thermodynamic burden on the engine. The design problem is thus to keep the metal below a prescribed temperature while limiting both coolant consumption and pressure loss [1,4].
Film cooling remains a major external-cooling method, but its performance depends on jet-in-crossflow behavior, density and momentum ratios, hole geometry, pressure gradients, surface curvature, turbulence, and downstream mixing [2,3,28,29]. Shaped holes can improve surface coverage and reduce jet lift-off [3]. Conventional discrete-hole systems, however, provide cooling at separated locations, and the resulting distribution need not follow the non-uniform heat load of a turbine airfoil.
Additive manufacturing has enlarged the range of internal-cooling geometries that can be produced. Triply periodic minimal surfaces (TPMS), in particular, provide continuous bicontinuous pathways, high interfacial area per unit volume, and adjustable porosity [6-10]. Gyroid and related TPMS structures can increase heat transfer relative to conventional channels, but the gain is accompanied by a pressure-loss penalty that becomes important at low Reynolds number [7-10]. Recent turbine studies have applied

TPMS concepts to trailing-edge lattices, leading-edge effusion, and double-wall cooling [13-15]. These studies also indicate that topology, porosity, wall thickness, and pressure loss need to be considered together.

Transpiration cooling provides another way to distribute coolant over a heated surface. In a porous wall, the coolant absorbs heat within the structure before reaching the external surface, reducing the heat load imposed on the wall [11,12,25-27]. Experiments with gyroid transpiration coupons show that injection ratio is a useful comparison parameter and that increasing porosity does not necessarily improve area-averaged effectiveness at a fixed injection ratio [11]. Numerical and experimental work on non-uniform permeability also shows that directing more coolant toward regions of higher heat load can improve thermal uniformity [12,25]. These findings provide a basis for considering graded architectures rather than simply increasing porosity.

The biomimetic basis for the geometry is tafoni, a class of cavernous weathering forms containing spatially varying cavities, ribs, and connected voids. Previous studies have related tafoni development to salt weathering, moisture transport, dynamical instability, and self-organization [20-23]. Computational biomimetic work has also used tafoni morphology as an input for generative architectural design [24]. There is, however, no established evidence that a tafoni-derived turbine-cooling structure outperforms a conventional TPMS. The geometry is therefore described here as tafoni-inspired, and the synthetic morphology is treated as a design input rather than a reproduction of natural rock-weathering physics.

The framework links morphology generation and measurement with a phase-consistent sheet-gyroid definition, literature-based TPMS heat-transfer and pressure-loss relations, and explicit coolant mass and enthalpy balances. Film and porous-effusion boundary modes are kept separate, while sensitivity, epistemic uncertainty, regime mapping, and analytical code checks are used to identify physically credible screening states. Quantitative findings are labeled by evidence source—verification, literature benchmark, ROM prediction, or hypothesis—so that preliminary screening is not confused with CFD or experimental validation.

2. Methodology

2.1. Tafoni-inspired morphology generation

The Gray-Scott reaction-diffusion system is used as a *morphology generator*, not as a complete physical model of tafoni weathering. The two interacting scalar fields are governed by

$$\frac{\partial u}{\partial t} = D_u \nabla^2 u - uv^2 + F(1-u) \qquad (1)$$

$$\frac{\partial v}{\partial t} = D_v \nabla^2 v + uv^2 - (F+k)v \qquad (2)$$

The Gray-Scott family is a well-established pattern-forming reaction-diffusion model [16-19]. Here it serves as a controllable generator of labyrinthine patterns with spatial variation resembling the selected tafoni features.

Figure 1 presents the thresholded morphology used for the screening analysis, the local two-dimensional void-fraction map, and a representative sheet-gyroid section obtained after morphology matching. The pattern is used quantitatively: its measured descriptors provide the inputs for the subsequent geometry mapping.

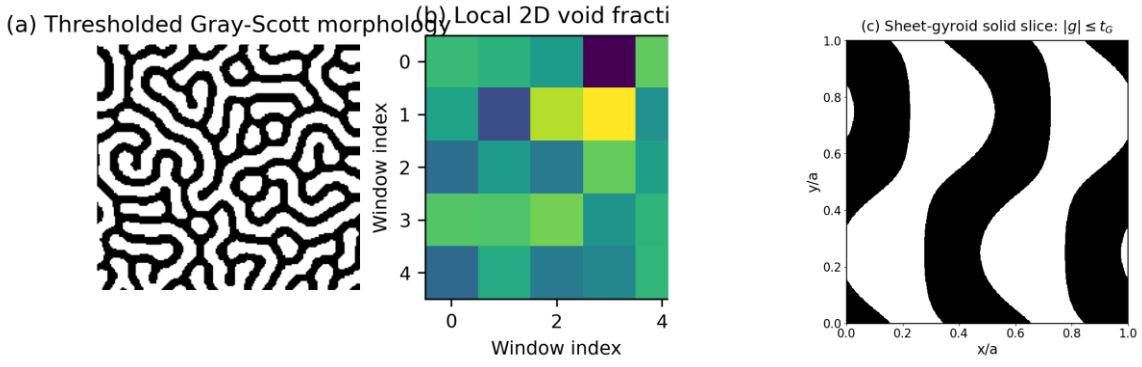

Figure 1. Quantified morphology-to-gyroid mapping. (a) Thresholded Gray–Scott pattern used as a tafoni-inspired morphology generator, (b) local two-dimensional void fraction, and (c) a representative

sheet-gyroid solid section at the morphology-matched threshold. In panel (c), black denotes the solid sheet $|g| \leq tG$ and white denotes the two complementary fluid labyrinths.

The two-dimensional void-area fraction is

$$A_A = \frac{A_{void}}{A_{total}} \qquad (3)$$

The measure in Eq. (3) refers to the two-dimensional morphology and should not be interpreted as a three-dimensional porosity measure. For the selected thresholded pattern, the value is approximately 0.46. Sampling with local 5×5 windows gives a coefficient of variation of approximately 6%, while the distance-transform/skeleton analysis gives a mean local void width of about 6.4 pixels, a median of 6.3 pixels, and an approximate 10th–90th percentile range of 5.7–8.0 pixels. These quantities are used for relative mapping only.

2.2. Gyroid definition and phase consistency

The physical gyroid coordinates are scaled through the unit-cell length a_G:

$$X = \frac{2\pi x}{a_G}, \qquad Y = \frac{2\pi y}{a_G}, \qquad Z = \frac{2\pi z}{a_G} \qquad (4)$$

The nodal gyroid approximation is [6]

$$g(X,Y,Z) = \cos X \sin Y + \cos Y \sin Z + \cos Z \sin X \qquad (5)$$

For a sheet thickness controlled by a level-set threshold tG, the solid sheet is defined by $|g| \leq tG$, while the two complementary fluid labyrinths occupy $g > tG$ and $g < -tG$, respectively.

$\Omega_s = \{|g| \leq t_G\}, \quad \Omega_{f+} = \{g > t_G\}, \quad \Omega_{f-} = \{g < -t_G\}$ (6)

The phase definition keeps the solid sheet and the two complementary fluid labyrinths mutually exclusive. Porosity and flow area are computed from the fluid domain actually used in the calculation. A single-labyrinth design therefore uses only one fluid region, whereas a dual-labyrinth sheet-gyroid design uses their combined fluid volume.

For the selected fluid domain, the geometric descriptors are

$$\varepsilon = \frac{V_f}{V_{tot}}, \qquad S_v = \frac{A_{sf}}{V_{tot}}, \qquad D_h = \frac{4\varepsilon}{S_v} \qquad (7)$$

The 2D-to-3D conversion is treated as a morphology-matching rule rather than a stereological validation. Numerical integration of the gyroid field with the sheet definition in Eq. (6) gives a combined dual-labyrinth void fraction $\varepsilon_{map} \approx 0.457$ at $tG \approx 0.830$, matching the present 2D target $AA \approx 0.457$. The local morphology envelope corresponds approximately to $tG \approx 0.75$–0.89.

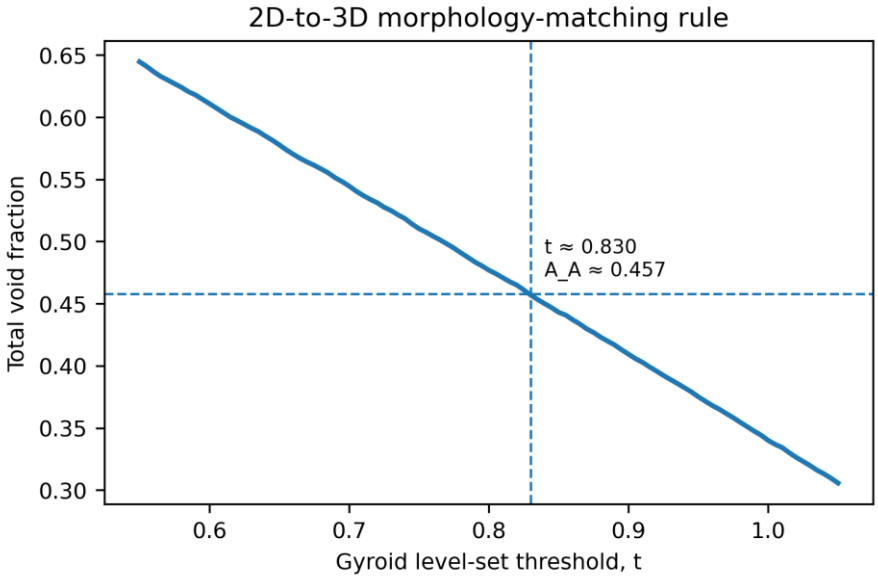

Figure 2. Numerical morphology-matching relation between the sheet-gyroid level-set threshold and the total void fraction. The dashed lines show the present 2D design target and the corresponding 3D gyroid threshold.

The local characteristic morphology width $d_T(\mathbf{x})$ is mapped to a graded gyroid cell size through

$$a_G(\mathbf{x}) = a_0 \frac{d_T(\mathbf{x})}{\overline{d}_T} \qquad (8)$$

The local-width mapping transfers relative spatial scale while preserving the morphology-mapping mean cell size aG,0 = 2.5 mm. For the present synthetic pattern, the resulting local cell-size range is approximately 2.28–2.78 mm; this modest variation does not support a claim of strongly multiscale grading.

Reference geometry convention. Three geometry levels are kept distinct. (i) The morphology-matched geometry uses aG,0 = 2.5 mm, tG ≈ 0.830, and εmap ≈ 0.457 for the two fluid labyrinths combined, with aG ≈ 2.28–2.78 mm. (ii) The generic ROM screening uses ε0 = 0.50 and aG = 2.0–2.5 mm as independent screening assumptions rather than morphology-derived values. (iii) The controlled grading mechanism test uses aG,0 = 2.5 mm with γ = 0.20, producing aG ≈ 2.08–3.04 mm at nearly fixed porosity and integrated internal area. Unless otherwise stated, ε denotes the combined fluid fraction of the two complementary labyrinths; a single-labyrinth implementation must recompute ε and the corresponding flow area.

2.3. Flow variables

For a reference cross-sectional envelope WH, the superficial and interstitial velocities are distinguished as

$$u_{sf} = \frac{\dot{m}}{\rho WH}, \qquad U_i = \frac{u_{sf}}{\varepsilon} \qquad (9)$$

The hydraulic Reynolds and Prandtl numbers are

$$Re_H = \frac{\rho U_i D_h}{\mu}, \qquad Pr = \frac{\mu c_p}{k_f} \qquad (10)$$

2.4. Thermal-resistance and coolant-energy model

The external gas convection, TBC conduction, metal conduction, and internal convection are represented by a series ROM:

$$R_g = \frac{1}{h_g A_e}, \quad R_{TBC} = \frac{t_{TBC}}{k_{TBC} A_e}, \quad R_m = \frac{t_m}{k_m A_c}, \quad R_i = \frac{1}{h_i A_i} \qquad (11)$$

This one-dimensional resistance network is a screening approximation and does not replace three-dimensional conjugate heat conduction in an actual blade.

The nodal heat transfer and coolant update are

$$q_i = \frac{T_{g,eff,i} - T_{c,i}}{R_g + R_{TBC} + R_m + R_i} \qquad (12)$$

$$h_{c,i+1} = h_{c,i} + \frac{q_i}{\dot{m}_i} \qquad (13)$$

With constant coolant heat capacity for verification, the enthalpy update reduces to the corresponding temperature-increment form.

2.5. Literature-informed internal heat-transfer closure

The primary gyroid heat-transfer closure is the experimental sheet-gyroid correlation of Reynolds et al. [9]:

$$Nu_G = 0.49 Re_H^{0.62} Pr^{0.4}, \qquad 100 < Re_H < 2500 \qquad (14)$$

The Reynolds et al. correlation is the primary literature-based internal heat-transfer relation used in the ROM; it was obtained from experimental TPMS heat-exchanger measurements over 100 < ReH < 2500 [9].

Iyer et al. [10] reported a lower-Reynolds-number gyroid trend at a substantially different Prandtl number. Its exponent is consequently retained for trend comparison, while its absolute correlation is not transferred to the present case:

$Nu_{I,*} = Nu_G(Re_0)\,(Re_H/Re_0)^{0.57}$, $Re_0 = 200$ (15)

For the low-Re comparison, only the published Reynolds-number exponent is retained, while the magnitude is anchored to the experimental air-side relation at the reference point.

For pressure-loss screening, the Iyer low-Re gyroid Fanning relation is converted to a Darcy factor:

$$f_D = 4 f_F = 62 Re_H^{-0.58} \qquad (16)$$

The Iyer pressure-loss relation is used only within its reported Reynolds-number range and for relative screening.
The corresponding pressure drop is

$$\Delta p = f_D \frac{L}{D_h} \frac{\rho U_i^2}{2} \qquad (17)$$

Figure 3 compares the three relations used in the thermal screening. The Reynolds correlation is the primary experimental relation, the Iyer curve provides a low-Reynolds-number trend check, and the Hausen relation is included only as a straight-channel reference.

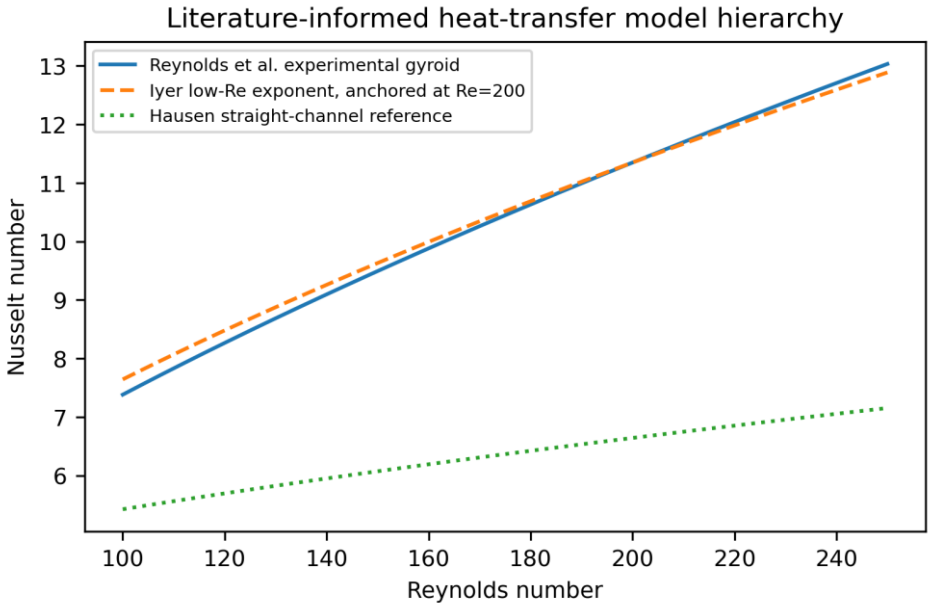

Figure 3. Heat-transfer model hierarchy. Reynolds et al. is the primary experimental gyroid relation; the anchored Iyer curve tests low-Re trend sensitivity; Hausen [30] is shown only as a straight-channel reference.

2.6. Energy-consistent discrete film model

Film extraction must remove mass from the internal coolant path:

$$\dot{m}_{i+1} = \dot{m}_i - \dot{m}_{f,i} \qquad (18)$$

The adiabatic wall temperature is represented by

$$T_{aw} = T_g - \eta_f (T_g - T_f), \qquad 0 \le \eta_f \le 1 \qquad (19)$$

The adiabatic-wall relation in Eq. (19) enforces $T_f \le T_{aw} \le T_g$.
In the current screening ROM, the film-side heat flux is written as

$$q''_{g,f} = h_{g0}(T_{aw} - T_w) \qquad (20)$$

In Eq. (20), the baseline gas-side coefficient is retained because an independently validated h_f/h_g model is unavailable. Film effectiveness is consequently an imposed boundary parameter in the ROM, rather than a prediction of detailed film-cooling behavior.

2.7. Porous effusion/transpiration mode

Film and porous-effusion modes are not applied simultaneously to the same surface element. For the porous mode, a blowing parameter is

$$B = \frac{\dot{m}'' c_{p,c}}{h_{g0}} \qquad (21)$$

The blowing parameter uses coolant heat capacity separately from the hot-gas property.
The screening blowing correction is

$$\frac{h_g(B)}{h_{g0}} = \frac{B}{e^B - 1} \qquad (22)$$

The blowing correction approaches the no-blowing limit as B → 0 and decreases monotonically with blowing.

An idealized coolant-enthalpy reference is defined as

$\dot{m}_{H,ref} = Q_{req} / [h_c(T_{lim}) - h_c(T_{in})]$ (23)

This coolant-enthalpy reference is based on the prescribed thermal load and the available coolant enthalpy rise and is used only as a screening reference.

2.8. Dimensionless screening metrics

Three dimensionless quantities are used to separate coolant-capacity, thermal-conductance, and hydraulic constraints:

$\Pi_H = \dot{m}_c [h_c(T_{lim}) - h_c(T_{in})] / Q_{req} = \dot{m}_c / \dot{m}_{H,ref}$ (24)

The enthalpy-sufficiency ratio is below unity when the available coolant enthalpy rise is insufficient for the prescribed thermal load.

$$\Pi_U = \frac{UA}{\dot{m}_c c_p} \qquad (25)$$

ΠU is an NTU-like ratio of thermal conductance to coolant heat-capacity rate.

$$\Pi_P = \frac{\Delta p}{\Delta p_{ref}} \qquad (26)$$

ΠP is retained as a relative hydraulic penalty because a validated turbine plenum-to-surface pressure budget is not available.

2.9. Baseline screening conditions

Table 1 summarizes the baseline quantities used in the ROM calculations. Values that are not established directly by experimental or literature evidence are identified as screening assumptions.

Table 1. Baseline screening conditions and assumptions.

Parameter	Value	Status
Hot-gas temperature, Tg	1700 K	nominal screening condition
Coolant inlet temperature, Tc,in	700 K	nominal screening condition
Gas-side coefficient, hg	2000 W m^-2 K^-1	screening assumption; sensitivity tested
Metal conductivity, km	22 W m^-1 K^-1	screening assumption; sensitivity tested
TBC conductivity, kTBC	1.1 W m^-1 K^-1	screening assumption; sensitivity tested
TBC thickness, tTBC	100 µm	screening assumption
Metal thickness, tm	1.0 mm	screening assumption
Mean gyroid cell size	2.5 mm nominal; 2.0–2.5 mm generic screening range	screening reference; morphology mapping uses 2.5 mm mean
Reference porosity, ε	0.50	generic dual-labyrinth screening reference; morphology match εmap ≈ 0.457
Reference Prandtl number	0.70	hot-air benchmark
Reference Reynolds number	200	common low-Re benchmark point
Initial coolant flow	0.600 g/s	reference input flow
Metal temperature limit	1300 K	screening constraint

The gas-side coefficient and the listed conductivity values are screening assumptions rather than measured blade properties; their influence is explicitly examined in the sensitivity analysis. The 0.600 g/s value is a reference input flow used for verification and regime assessment, whereas 0.768 g/s is the nominal coolant requirement obtained later from the screening calculation.

3. Verification and Evidence Controls

3.1. Exact mass and enthalpy conservation

The global mass residual is

$$R_m = \dot{m}_{in} - \dot{m}_{out} - \sum_j \dot{m}_{f,j} \qquad (27)$$

The mass residual in Eq. (27) checks that every discrete film extraction is removed from the internal coolant circuit.

The global coolant-energy residual is

$$R_E = \dot{m}_{in} h_{in} + \sum_i q_i - \dot{m}_{out} h_{out} - \sum_j \dot{m}_{f,j}\, h_{f,j} \qquad (28)$$

The energy residual in Eq. (28) checks the enthalpy balance for the remaining coolant and the extracted film stream. In the representative verification case, 0.600 g/s enters the domain and 0.150 g/s is extracted, leaving 0.450 g/s at the outlet. The residual is at numerical roundoff level, verifying the bookkeeping equations independently of the external film-cooling closure.

3.2. Analytical axial-solution verification

For constant UA, constant hot-gas temperature, and constant coolant heat capacity, the exact one-dimensional solution is

$T_{c,out} = T_g - (T_g - T_{c,in}) \exp[-UA/(\dot{m}\, c_p)]$ (29)

Using Tg = 1700 K, Tc,in = 700 K, ṁ = 0.600 g/s, cp = 1100 J kg^{-1} K^{-1}, and a verification-only UA = 0.12 W/K gives Tc,out = 866.247 K. The ROM error decreases approximately in proportion to Nx^{-1}, consistent with the first-order axial update. At Nx = 200, the outlet-temperature error is about 0.069 K (0.008%), while the associated maximum-wall-temperature difference is about 0.029 K.

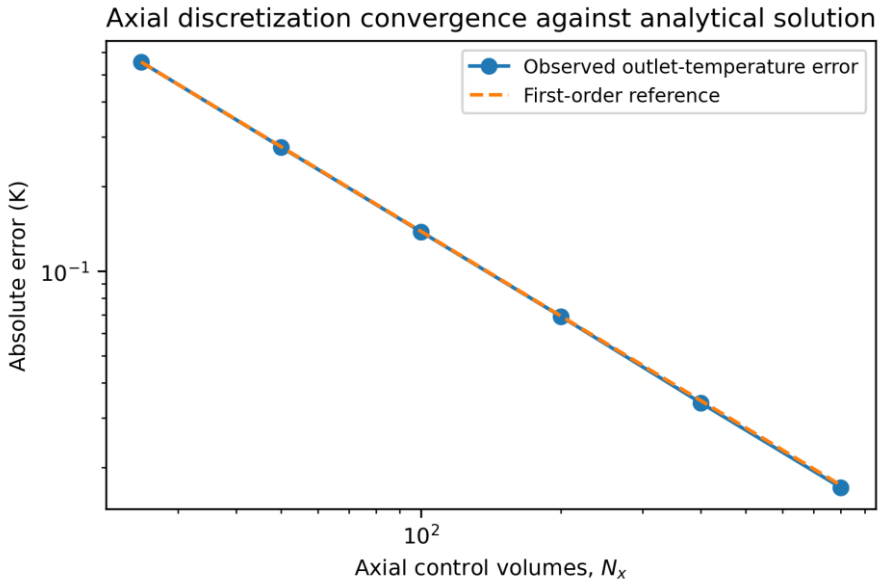

Figure 4. Axial discretization convergence against the analytical constant-UA solution. The observed slope is consistent with first-order convergence.

The same analytical model also recovers the physically required limiting behavior. As ṁ → 0, the coolant approaches the hot-gas temperature and heat removal becomes coolant-capacity limited; as ṁ → ∞, the outlet approaches the inlet temperature and total heat transfer approaches UA(Tg − Tc,in).

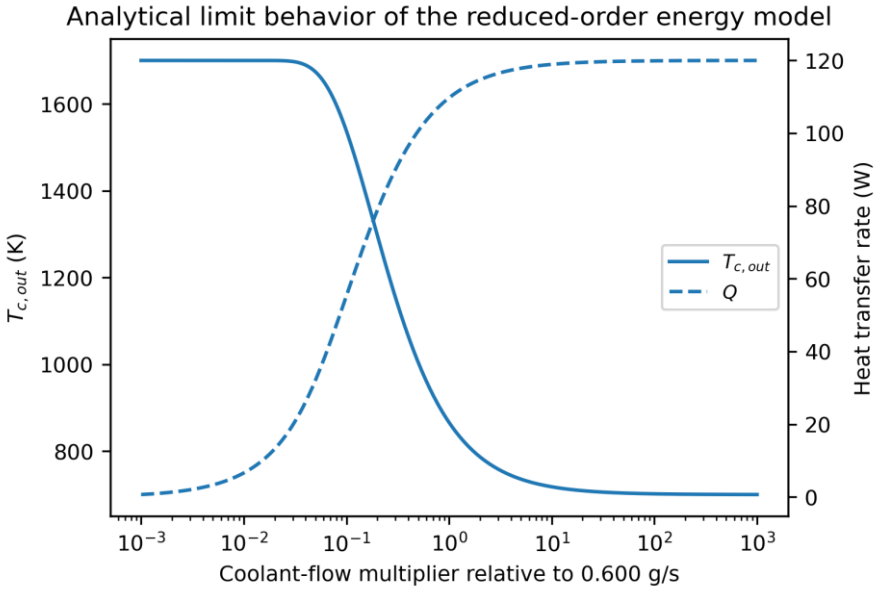

Figure 5. Analytical limiting behavior of the reduced-order energy model as coolant flow is varied over six decades.

These limits lead directly to

$$Q = \dot{m}\, c_p\, (T_g - T_{c,in})\, [1 - \exp(-\Pi_U)] \quad (30)$$

The analytical limits show that $\Pi U \ll 1$ corresponds to heat-transfer control, whereas $\Pi U \gg 1$ approaches coolant-capacity control. The transition is continuous rather than universally enthalpy-limited.

4. Results and Discussion

4.1. Literature benchmark at the reference operating point

At $Re_H = 200$ and Pr = 0.70, Eq. (14) gives $Nu_G \approx 11.35$. The Hausen straight-channel reference [30], evaluated at the same reference operating point, is approximately 6.64, so the Reynolds gyroid relation is about 1.71 times higher under the definitions adopted here. This agrees in direction with the experimental enhancement reported for gyroid TPMS relative to straight channels [9] and is used as a literature benchmark for the ROM.

The absolute Iyer gyroid correlation is not applied to the hot-air case because its Prandtl-number range differs substantially from that considered here. Retaining only its Reynolds exponent and anchoring the curve at ReH = 200, the difference from the Reynolds experimental relation is only a few percent over the common $100 \leq ReH \leq 250$ interval. The larger uncertainty is associated with transferring an absolute correlation across geometry, temperature field, wall condition, and manufactured surface rather than with the exponent difference of 0.57 versus 0.62.

Table 2. Literature-model hierarchy used by the ROM.

Source/model	Role in present study	Directly used as absolute turbine correlation?
Reynolds et al. [9]	Primary experimental sheet-gyroid Nu closure	Yes, for literature-informed screening within range
Iyer et al. [10]	Low-Re exponent and friction-factor trend	No for absolute Nu at hot-air Pr
Hausen laminar channel form [30]	Straight-channel reference only	No

Source/model	Role in present study	Directly used as absolute turbine correlation?
Brimacombe et al. [11]	Gyroid transpiration behavior benchmark	No direct coefficient transfer

4.2. Single-parameter sensitivity

A ±20% one-at-a-time analysis was used to identify the inputs with the largest influence on required coolant flow and maximum wall temperature. Gyroid cell size, the gas-side heat-transfer coefficient, and the transferred gyroid Nusselt level dominate the response. Cell size shows the clearest geometry trade-off: reducing it increases area density and shortens the hydraulic length scale, which lowers temperature, while the hydraulic penalty rises. Coolant flow is also varied in this OAT sweep as a control/design variable, but it is not treated as an independent epistemic input in the uncertainty propagation because the required coolant flow is the solved response.

Table 3. Selected ±20% screening responses for maximum metal temperature.

Variable	Low-side Tmax (K)	High-side Tmax (K)	Interpretation
Cell size aG	1295.8	1368.9	strongest geometry effect; smaller is cooler but hydraulically costly
Gas-side hg	1296.3	1365.3	strong imposed-load uncertainty
Coolant flow m-dot	1367.3	1309.4	more coolant reduces temperature but increases pressure loss
Gyroid Nu level	1365.2	1312.0	major correlation-transfer uncertainty
Film effectiveness ηf	1347.9	1323.8	moderate local effect
Porosity ε	1347.1	1326.8	moderate effect in current setup
kTBC	1328.3	1341.0	smaller effect than dominant variables
tTBC	1342.1	1329.8	smaller effect than dominant variables

The local uncertainty surrogate attributes about 91% of the response variance to the first three inputs. This result identifies the variables that should receive priority in subsequent CFD or experimental work.

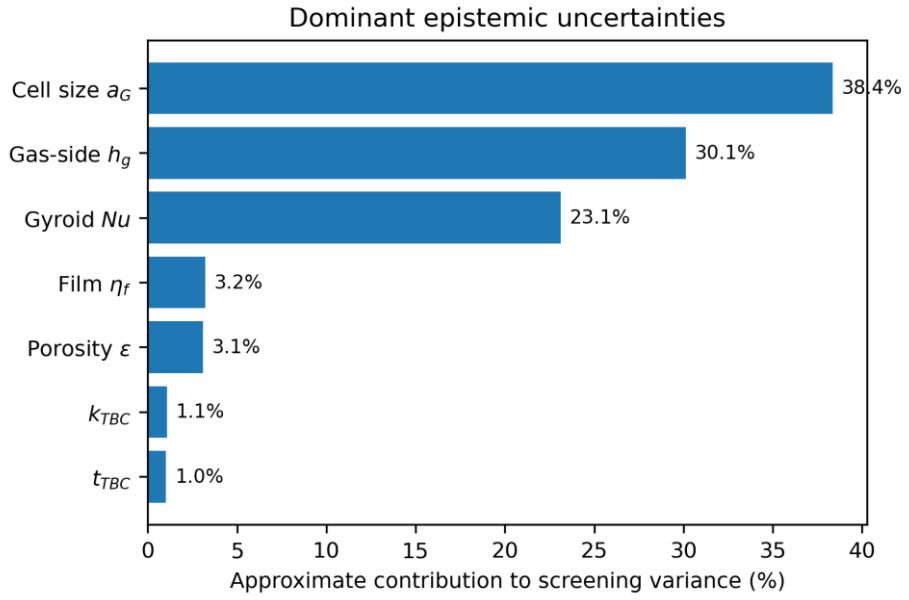

Figure 6. Approximate contribution of each epistemic input to the local coolant-requirement variance.

4.3. Epistemic uncertainty and robust screening

A local quadratic response surface was fitted through the -20%, nominal, and +20% points for each uncertain variable:

$$\dot{m}_{req} = \dot{m}_{req,0} + \sum_i \left(A_i \delta_i + B_i \delta_i^2\right) \qquad (31)$$

With seven independent uniform epistemic model inputs over ±20% and 200,000 random combinations, the solved nominal coolant requirement $\dot{m}_{req,0} = 0.768$ g/s broadens into the distribution summarized in Table 4. Coolant flow itself is not sampled as an eighth epistemic input; it is the response solved from each uncertainty realization. The 95th-percentile screening value is approximately 1.12 g/s, showing that a single nominal flow is not robust to the adopted epistemic uncertainty range.

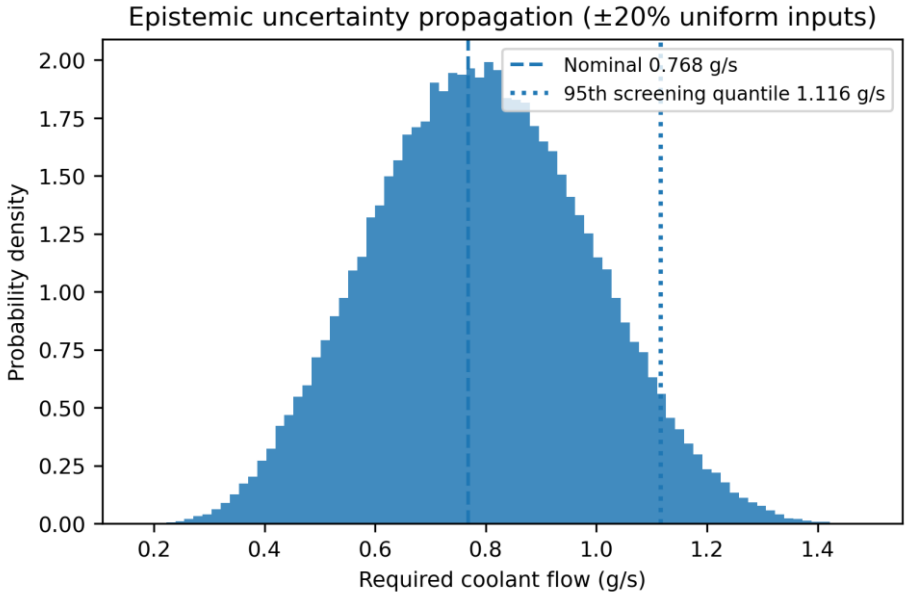

Figure 7. Distribution of the required coolant flow obtained by propagating independent ±20% epistemic uncertainties through the local ROM surrogate.

Table 4. Epistemic uncertainty summary.

Quantity	Screening result
Nominal required coolant	0.768 g/s
Mean required coolant	0.792 g/s
Median required coolant	0.789 g/s
5th percentile	0.476 g/s
95th percentile	1.116 g/s
99th percentile	1.239 g/s
Coverage at 0.768 g/s	≈46% of epistemic box
Coverage at 1.12 g/s	≈95% of epistemic box
Interpretation	screening quantiles, not engine reliability probabilities

A deterministic optimum coolant flow is therefore insufficient when the input uncertainty is appreciable.

4.4. Thermal-capacity and pressure-loss regime map

At fixed fluid properties and cross-sectional envelope, the mass flow scales as

$$\frac{\dot{m}}{\dot{m}_0} = \frac{Re_H}{Re_0}\frac{\varepsilon}{\varepsilon_0}\frac{a_{G,0}}{a_G} \qquad (32)$$

Using the nominal coolant requirement as the capacity threshold gives, for the adopted normalization,

$$Re_T = 64\frac{a_G[\mathrm{mm}]}{\varepsilon} \qquad (33)$$

The thermal-capacity boundary is relative to the adopted normalization and is not a universal transition Reynolds number.

Combining Eq. (16) with $D_h \propto a_G$ gives the approximate pressure scaling

$$\frac{\Delta p}{\Delta p_0} = \left(\frac{Re_H}{200}\right)^{1.42}\left(\frac{2}{a_G[\mathrm{mm}]}\right)^{3} \qquad (34)$$

This scaling highlights the strong hydraulic penalty associated with reducing cell size under the low-Reynolds-number pressure-loss model.

A relative pressure threshold $\Pi_P = 1$ defines the screening boundary $Re_P(a_G)$. Figure 8 shows that very small cells may leave little feasible operating range because the required coolant flow is reached only after the pressure penalty has become large. The key observation is the separation between the thermal-capacity and hydraulic boundaries rather than a unique optimum cell size.

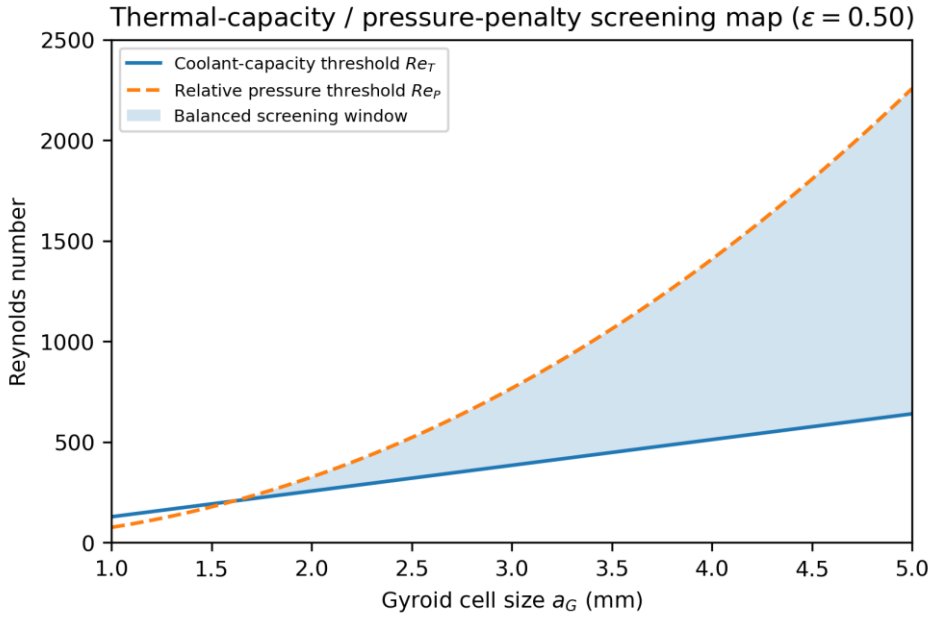

Figure 8. Thermal-capacity and pressure-penalty screening map at ε = 0.50. The shaded region denotes the relative design window under the generic screening assumptions.

4.5. Mixed heat-transfer/coolant-capacity control

The enthalpy-sufficiency ratio is evaluated from Eq. (24) as $\Pi_H = \dot{m}_c / \dot{m}_{H,ref}$, where $\dot{m}_{H,ref}$ is defined by Eq. (23) from the prescribed thermal load and available coolant enthalpy rise. The solved ROM requirement of 0.768 g/s is not the enthalpy-reference flow and is therefore not used as the denominator of Π_H. No numerical Π_H is inferred from 0.600/0.768. The strong sensitivity of required flow to the Nusselt level, together with the analytical Π_U limiting behavior, supports a mixed heat-transfer/coolant-capacity interpretation.

The screening state is therefore described as mixed heat-transfer/coolant-capacity controlled, with an additional hydraulic constraint.

4.6. Uniform versus load-matched graded surrogate

A separate mechanism test compares a uniform gyroid with a load-matched graded surrogate at nearly equal porosity and integrated internal area. The 1300 K value is used only as the temperature constraint in the separate nominal-flow screening calculation. In the grading mechanism test, 0.768 g/s is carried over only as a common reference flow and the wall temperature is allowed to emerge from the surrogate comparison; it is not forced to 1300 K. The grading rule is

$$\frac{1}{a_G(x)} = \frac{1}{a_0}[1 + \gamma\psi(x)], \qquad \left\langle \frac{1}{a_G} \right\rangle = \frac{1}{a_0} \qquad (35)$$

For γ = 0.20 and aG,0 = 2.5 mm, the controlled surrogate spans approximately 2.08–3.04 mm. At the common reference flow of 0.768 g/s, the uniform surrogate settles at 1107.2 K and the graded surrogate at 1088.5 K. The difference from the 1300 K screening constraint is expected because that constraint is not imposed in this mechanism test; 0.768 g/s is used only to place both surrogate geometries at the same flow for comparison. Using the uniform-case temperature of 1107.2 K as the matching target, the graded case requires about 0.704 g/s, corresponding to an 8.3% ROM-level reduction. The associated relative pressure measure is approximately 0.888 because the lower flow also reduces the hydraulic penalty.

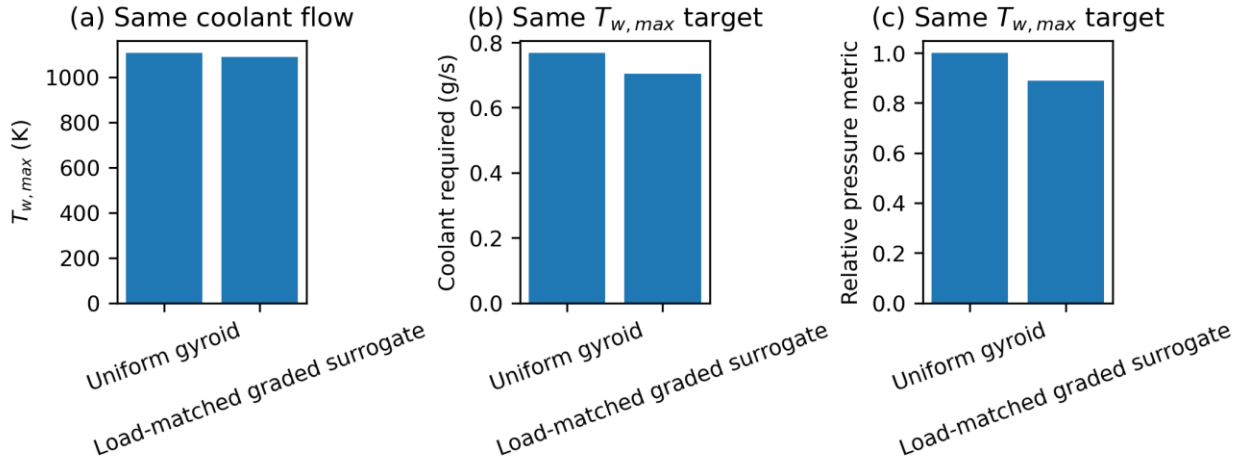

Figure 9. Comparison of the uniform and load-matched graded gyroid surrogates in the controlled ROM mechanism test.

The comparison indicates that spatial redistribution can be beneficial within the ROM, but the same gain cannot be assigned directly to the measured Gray-Scott morphology. The measured pattern varies by only about ±10% around a 2.5 mm mean cell size, whereas the controlled mechanism test uses ±20% grading. The mechanism-test result is therefore retained as a surrogate finding rather than a performance claim for the tafoni-inspired geometry.

4.7. Morphology-derived grading range and interpretation

The measured synthetic pattern shows moderate local variability. These measurements support the term tafoni-inspired morphology-derived gyroid, but they do not imply that a natural tafoni structure has been reconstructed. The mapping chain used here is

$$\text{Gray-Scott morphology} \rightarrow \{A_A, d_T, L_A\} \rightarrow \{a_G(\mathbf{x}), t_G(\mathbf{x})\} \qquad (36)$$

This mapping converts the morphology measurements into a quantitative geometry rule while retaining the limitations of the 2D-to-3D conversion.

4.8. External-cooling physical admissibility

Three mutually exclusive wall modes are enforced: internal-only, discrete-film, and porous-effusion/transpiration. This rule prevents the same external heat-flux reduction from being counted simultaneously through both T_{aw} and a transpiration blowing correction. All accepted screening states must also satisfy

$T_{c,in} \le T_c(x) \le T_w(x) \le T_{aw}(x) \le T_g$ (37)

The admissibility filter excludes states that violate the prescribed temperature ordering.

In a future pressure-coupled film model, film flow should depend on local hole geometry and pressure difference rather than being treated as an independent design variable. A low-Mach screening relation is

$$\dot{m}_f = C_d A_h \sqrt{2\rho_c(p_{pl} - p_s)} \qquad (38)$$

The low-Mach relation is used only for screening; compressibility and possible choking must be included for high-pressure turbine conditions.

5. Evidence Level, Limitations, and Scope

Table 5 distinguishes mathematical verification, literature-supported benchmarks, ROM-level mechanism tests, and hypotheses.

Table 5. Evidence and claim hierarchy of the present manuscript.

Statement	Evidence level	Allowed interpretation
Internal coolant mass/enthalpy balance closes	Mathematical/code verification	Demonstrated within ROM equations
Axial solution converges at first order	Analytical verification	Demonstrated
Gyroid Nu is higher than straight-channel reference	Literature benchmark	Supported for published sheet-gyroid range
Gyroid pressure loss can be much higher than laminar pipe flow	Literature benchmark	Supported, regime dependent
Load-matched graded surrogate reduces coolant requirement in ROM	Controlled ROM mechanism test	Supported as screening-level finding
Current Gray–Scott morphology is strongly multiscale	Morphology measurement	Not supported; variability is modest
Tafoni-inspired graded geometry has real-engine advantage	Hypothesis	CFD/experiment required
Effusion reaches a universal thermodynamic lower bound	Not supported	Use idealized coolant-enthalpy reference instead
Model predicts validated engine performance	Not supported	Use verified/literature-benchmarked ROM terminology

The main limitations arise from the screening-level boundary conditions and from transferring published gyroid heat-transfer data to a turbine context. Surface roughness, compressibility, rotation, curvature, and the higher temperature levels of an actual turbine have not been independently validated here. The morphology is a synthetic Gray-Scott pattern rather than a three-dimensional scan of natural tafoni, and the sheet-gyroid geometry has not yet been assessed for minimum printable wall thickness, stress concentration, centrifugal loading, oxidation, or TBC compatibility. The porous-effusion pressure budget is therefore reported only in relative form, and the present study contains no new CFD or experimental measurements.

Accordingly, the present results define a physics-constrained preliminary-design screening framework for subsequent CFD and experimental assessment.

6. Conclusions

The reduced-order model provides a preliminary assessment of a tafoni-inspired graded gyroid TPMS concept for turbine-blade cooling. The main conclusions are:

1. A quantitative morphology-to-gyroid mapping replaces a purely visual analogy. The selected Gray–Scott pattern is represented by void fraction, local width, and interface density, and the sheet-gyroid definition uses the mutually exclusive regions $|g| \leq tG$, $g > tG$, and $g < -tG$. The morphology-matched case uses $aG,0 = 2.5$ mm, $tG \approx 0.830$, and $\varepsilon map \approx 0.457$, with local $aG \approx 2.28$–2.78 mm.
2. Published sheet-gyroid data provide the primary internal heat-transfer benchmark. At $ReH = 200$ and $Pr = 0.70$, the Reynolds correlation gives $NuG \approx 11.35$, compared with about 6.64 for the Hausen straight-channel reference. The Iyer low-Re relation is retained for trend and pressure-loss screening rather than transferred as an absolute hot-air correlation.
3. The ROM conserves coolant mass and enthalpy, separates discrete-film and porous-effusion boundary modes, and reproduces the expected analytical limits. The axial discretization exhibits first-order convergence, with the 200-control-volume verification error below 0.01%.

4. The screening state is mixed heat-transfer/coolant-capacity controlled and is additionally constrained by hydraulic loss. The enthalpy-sufficiency metric must be referenced to $\dot{m}_{H,ref}$ from Eq. (23), not to the solved 0.768 g/s ROM requirement.
5. Epistemic uncertainty substantially broadens the coolant requirement. Cell size, gas-side heat-transfer coefficient, and the transferred gyroid Nusselt level account for most of the local response variance and should receive priority in subsequent CFD and experiments.
6. In the controlled grading mechanism test, the graded surrogate lowers the hotspot from 1107.2 K to 1088.5 K at the common 0.768 g/s reference flow and reduces the flow required to match the uniform-case 1107.2 K target from 0.768 to 0.704 g/s. This result applies to the controlled surrogate comparison and should not be assigned directly to the measured tafoni-inspired morphology.

The next stage should be a morphology-specific RVE or full conjugate CFD study to determine heat-transfer coefficients, pressure drop/permeability, and local thermal fields for the mapped gyroid. The same uniform and graded architectures can then be tested experimentally under matched coolant-flow and pressure conditions. Until such evidence is available, the ROM is best used to identify promising design regions, quantify uncertainty, and exclude physically inconsistent cooling concepts.

RARE-EARTH-DOPED YSZ SMART OPTICAL SENSOR COATINGS FOR GAS-TURBINE AND JET-ENGINE TURBINE BLADES: A LITERATURE-BASED MULTI-CRITERIA FRAMEWORK WITH DATA-SUFFICIENCY SCREENING FOR TEMPERATURE AND STRUCTURAL HEALTH MONITORING

Abstract
The primary function of thermal barrier coatings (TBCs) used in the hot sections of gas turbines and aviation jet engines is to protect metallic turbine blades from high temperatures. In next-generation engines, however, thermal insulation alone is not sufficient; non-contact monitoring of coating temperature, thermal history, and, where possible, damage indicators such as stress, deformation, cracking, and delamination is also desirable. Yttria-stabilized zirconia (YSZ) doped with rare-earth ions is attractive for this purpose because it can combine the well-established thermal-barrier behavior of YSZ with the photoluminescence properties of rare-earth ions within the same material family. In this study, six optically active ions—Tm^{3+}, Ho^{3+}, Nd^{3+}, Er^{3+}, Eu^{3+}, and Dy^{3+}—were evaluated as alternative or architecture-dependent sensor activators for YSZ rather than as a mixture to be incorporated simultaneously into a single coating.
The aim of this study is to evaluate the available experimental evidence for Tm^{3+}, Ho^{3+}, Nd^{3+}, Er^{3+}, Eu^{3+}, and Dy^{3+} within a common data structure, identify missing data, and establish a MATLAB framework to guide subsequent experiments. Concentration-dependent photoluminescence intensity I(c), fluorescence intensity ratio FIR(T), fluorescence lifetime τ(T), and thermal conductivity k(c,T) were treated as the principal data groups. The literature reports photoluminescence peak concentrations of approximately 0.50 mol% for Tm^{3+}, approximately 0.50–0.75 mol% for Ho^{3+} depending on the study, and approximately 0.75 mol% for Nd^{3+}. Er^{3+} provides strong evidence for high-temperature thermal-history sensing, while coating-scale thermometry studies are available for Eu^{3+} and Dy^{3+}; experimental studies on stress and delamination monitoring are also available for Eu^{3+}- and Er^{3+}-based systems.
Absolute photoluminescence intensities were not compared directly because the host phase, processing method, excitation power, optical collection geometry, and specimen configuration differ among studies. For Tm^{3+}, the distinct PL peak at approximately 0.50 mol% and the blue emission near 458 nm provide a practical starting point for subsequent concentration scans. Curve fitting of six digitized Ho^{3+} data points from Yang et al. [7] yielded c_{peak} = 0.475 mol%, R^2 = 0.874, and RMSE = 0.068. Because high-temperature optical calibration, low-dopant k(c,T) data, and SHM calibration are not available together for the same candidate under comparable coating conditions, multi-criteria ranking and PSO were not applied.
At this stage, the study defines an experimental roadmap for generating comparable data rather than producing a material ranking. The main requirements are high-temperature FIR(T)/τ(T) calibration, photoluminescence–stress calibration, controlled crack/delamination imaging, thermal-cycling durability, and k(c,T) measurements. Once these data sets are completed, the multi-criteria QPI and PSO approach can be used to support material, concentration, and coating-architecture selection.
Keywords: thermal barrier coating; YSZ; rare-earth doping; photoluminescence; optical thermometry; structural health monitoring

Highlights
- Six rare-earth ions were compared as separate candidate systems for YSZ-based optical sensor coatings.
- The PL peak near 0.50 mol% for Tm^{3+} provides a practical starting point for subsequent comparative experiments.
- Er^{3+} provides strong evidence for high-temperature thermal-history sensing; direct experimental evidence exists for stress and delamination monitoring with Eu^{3+}, and related evidence for delamination monitoring with Er^{3+}/Yb^{3+}- and Er^{3+}-based systems.
- The Ho^{3+} curve-fitting test yielded c_{peak} = 0.475 mol%, R^2 = 0.874, and RMSE = 0.068.

- The current data set is insufficient for full QPI/PSO comparison; the missing data groups should be completed through targeted experiments.

1. Introduction

Gas turbines and jet engines operate at increasingly high turbine inlet temperatures to achieve higher efficiency. Under these conditions, direct exposure of nickel-based superalloy turbine blades to hot gases would impose unacceptable thermal loads and oxidation. Ceramic thermal barrier coatings are therefore used on hot-section components such as turbine blades, vanes, and combustion chambers. YSZ-based TBCs have long been a key industrial solution because of their low thermal conductivity, compatible thermal expansion, and mature coating technologies [1]. At operating temperatures above 1200 °C, however, phase transformation, sintering, thermal radiation, interfacial stresses, thermally grown oxide (TGO) formation, and crack/delamination growth can limit coating life [1,2,13].

The central approach of this study is to add optical interrogation capability to the thermal-protection function of the TBC. A coating containing an appropriate amount of optically active rare-earth ions can be excited by a laser or another light source at a suitable wavelength; the intensity, spectral ratio, or decay lifetime of the emitted photoluminescence signal can then be measured remotely. This enables temperature and thermal-history information to be obtained without embedding wires or conventional contact sensors in the coating [3,4,14–16].

A further objective is to enable structural health monitoring (SHM) through the coating. Stress, strain, microcracking, delamination, or partial separation within the coating can alter the photoluminescence peak position, linewidth, intensity, or the optical reflection/scattering path. Experimental studies have shown that residual-stress distributions and their evolution during thermal cycling can be measured in Eu^{3+}-doped YSZ coatings by photoluminescence piezospectroscopy; delamination can be detected with high contrast using YSZ:Eu luminescent sublayers; and subcritical delamination-crack growth can be monitored by luminescence imaging in Er^{3+}/Yb^{3+}-doped YSZ [17–20]. Rare-earth-doped YSZ sensor coatings have also been reported to exhibit high-temperature strain/stress behavior close to that of conventional YSZ [21]. These studies show that the smart-TBC concept is supported by experimental evidence rather than being solely a theoretical proposal.

A critical scientific distinction is nevertheless required. Strong photoluminescence from a given ion does not necessarily mean that the same ion is also the best high-temperature thermometer, stress sensor, or crack indicator. Likewise, the dopant concentration that gives the highest room-temperature luminescence intensity may not provide the highest thermometric sensitivity or the lowest thermal conductivity in the 1200–1500 K range. Processing route, Y_2O_3 content, crystal phase, porosity, grain structure, excitation wavelength, optical collection geometry, and coating thickness can substantially affect the results [2,3,13]. This variability makes it unreliable to select a single “best ion” directly from absolute luminescence intensities reported in different studies.

This study evaluates concentration–photoluminescence data for Tm^{3+}, Ho^{3+}, and Nd^{3+}; high-temperature thermal-history data for Er^{3+}; and coating-scale thermometry evidence for Eu^{3+} and Dy^{3+}. The six ions are treated as separate sensor candidates rather than as a formulation to be added simultaneously to one coating. Specific multilayer or multi-activator architectures may be investigated separately in future work.

The main contributions of the study are the separation of different experimental data types within a common record structure, withholding multi-criteria ranking when data are incomplete, demonstration of curve fitting and peak-position reproduction using Ho^{3+} data, and inclusion of stress/damage-monitoring requirements in the experimental roadmap in addition to temperature sensing.

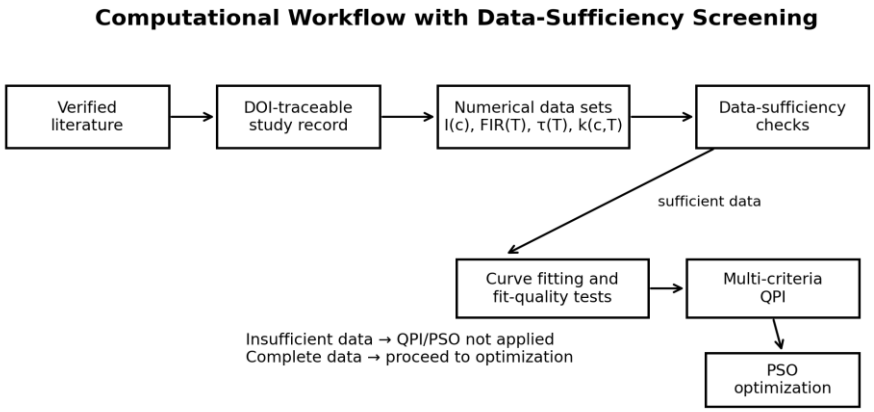

Figure 1. Computational workflow with data-sufficiency screening. The QPI/PSO stage is not entered until the required experimental data groups are available.

2. Literature-Based Experimental Evidence

2.1. Literature search and evidence selection

Candidate studies were identified in Web of Science, Scopus, ScienceDirect, SpringerLink, and Google Scholar using combinations of the keywords YSZ, stabilized zirconia, Tm^{3+}, Ho^{3+}, Nd^{3+}, Er^{3+}, Eu^{3+}, Dy^{3+}, photoluminescence, fluorescence intensity ratio, lifetime thermometry, thermal-history sensor, thermal barrier coating, thermal conductivity, photoluminescence piezospectroscopy, stress, and delamination. Studies were entered into the data record if they used YSZ or a closely related stabilized-zirconia host, provided at least one quantitative data set or experimental reference point, and were bibliographically verifiable.

The search was not designed as a complete PRISMA-type systematic review, but as a source-verified data-selection process for the computational framework. PL peak values, high-temperature results, and measurement modes from different studies were not merged into a single material curve; each study was retained separately with its host phase, processing route, concentration range, excitation–emission conditions, and measurement mode.

2.2. Tm^{3+}-doped YSZ

Xu et al. produced cubic YSZ single crystals containing 0.2–3.0 mol% Tm_2O_3 by the optical floating-zone method [5]. Under 356 nm excitation, strong blue emission near 458 nm and weaker emission bands at longer wavelengths were reported. Luminescence intensity increased at low Tm_2O_3 concentrations, reached a maximum at approximately 0.50 mol%, and then decreased at higher dopant levels because of concentration quenching.

The approximately 0.50 mol% peak reported by Xu et al. [5] is an experimental PL maximum for Tm^{3+} and provides a reference value for subsequent concentration scans. It is not interpreted here as an optimum for high-temperature thermometry, stress measurement, or crack detection.

2.3. Ho^{3+}-doped YSZ

Tan et al. reported strong emission near 553.5 nm under 448 nm excitation in Ho^{3+}-doped YSZ single crystals [6]. Ho_2O_3 contents of 0.20, 0.50, 0.75, 1.00, 1.50, and 2.00 mol% were evaluated, and the strongest fluorescence was observed at approximately 0.75 mol%.

Yang et al. investigated 0–1.20 mol% Ho_2O_3 in a related Y_2O_3-stabilized ZrO_2 system, reported emission bands near 540, 551, 670, and 757 nm under 446 nm excitation, and found maximum luminescence at approximately 0.50 mol% [7]. The quenching observed at higher concentrations was attributed to electric dipole–dipole interactions.

The different Ho^{3+} peak concentrations reported in the two studies, 0.75 and 0.50 mol%, show that the optimum dopant level does not depend on ion identity alone. Because the host phase, Y_2O_3 content, crystal phase, processing method, and measurement protocol differ, these results were retained as separate experimental reference values.

2.4. Nd^{3+}-doped YSZ

Zhang et al. produced YSZ single crystals containing 0.30–1.50 mol% Nd_2O_3 by the optical floating-zone method and evaluated both up-conversion luminescence and Judd–Ofelt analysis [8]. The maximum emission intensity reported near 0.75 mol% Nd_2O_3 was retained in the record as the reference peak value, while excitation/emission conditions and the concentration-quenching mechanism were stored as study metadata.

As with Tm^{3+} and Ho^{3+}, the 0.75 mol% value for Nd^{3+} is only the photoluminescence optimum under the specific experimental conditions of the source study. Real-time temperature or damage monitoring on a turbine blade requires high-temperature calibration for the intended measurement mode.

2.5. Er^{3+}-doped YSZ

Among the six selected candidates, Er^{3+} has the strongest direct evidence for high-temperature thermal-history sensing. Copin et al. prepared a YSZ system containing 8.3 mol% $YO_{1.5}$ and 1.5 mol% $ErO_{1.5}$ (0.75 mol% Er_2O_3-equivalent) by a sol–gel route and applied 15 min isothermal exposures between 1173 and 1423 K [9]. Permanent changes in emission intensity and fluorescence lifetime were used to estimate the temperature to which the specimen had previously been exposed. This was not instantaneous/in-situ thermometry, and the 1.5 mol% Er composition was not presented as a concentration optimum.

Amiel et al. compared intensity-ratio and lifetime-based methods in a YSZ:Er^{3+}/YSZ:Eu^{3+} fluorescent thermal-history sensor and reported good thermal sensitivity over 1223–1423 K [10]. Er^{3+} records were therefore retained separately as thermal-history-sensing data.

Er^{3+} is also relevant to delamination detection. Eldridge and Wolfe monitored subcritical delamination-crack growth in Er^{3+}/Yb^{3+}-doped YSZ by up-conversion luminescence imaging [18]. Fouliard et al. modeled and experimentally quantified delamination contrast in TBC configurations containing an Er^{3+}-doped YSZ luminescent layer [19]. These studies support delamination monitoring within the Er^{3+} family; their compositions and measurement modes were not combined with the thermal-history data into a single numerical curve.

2.6. Eu^{3+}-doped YSZ

For Eu^{3+}, direct YSZ:Eu evidence was evaluated separately from evidence obtained using a different-host phosphor beneath a YSZ top coat. Feist and Heyes showed that the emission decay lifetime of YSZ:Eu is temperature dependent over approximately 299–1073 K (26–800 °C) and that the 591 and 607 nm emission lines can be used for thermometry [14]. Yang et al. demonstrated direct YSZ:Eu sensor-TBC operation over approximately 400–800 °C [11]. Abou Nada et al. used a Y_2O_3:Eu luminescent layer beneath an APS YSZ top coat to perform remote temperature measurement through the YSZ [3]. Because Y_2O_3:Eu is not the same host as YSZ:Eu, this study was retained as related coating-scale optical-access evidence and was not included directly in the YSZ:Eu temperature-window calculation.

A second important role of Eu^{3+} in this study is the evidence for stress and damage sensing. Eldridge et al. experimentally demonstrated a self-indicating coating concept using a YSZ:Eu luminescent sublayer, observing a pronounced emission increase in TBC delamination regions [17]. Zhao et al. used the relationship between the peak position of the $^5D_0 \rightarrow {}^7F_2$ transition and stress in an 8YSZ:Eu coating to monitor residual-stress distribution and its evolution during thermal cycling at 1300 °C by photoluminescence piezospectroscopy [20]. These studies provide positive experimental evidence that the coating can act as a sensor of mechanical condition as well as temperature.

The selected direct YSZ:Eu in-situ thermometry evidence nevertheless has an upper limit of approximately 1073 K, below the 1200–1500 K engineering window. Thus, although Eu^{3+} is a strong SHM reference, additional high-temperature validation is required for thermometry in the turbine-relevant window.

2.7. Dy^{3+}-doped YSZ

Dy^{3+}-doped YSZ is an important high-temperature reference for intensity-ratio and lifetime-based thermometry. Abou Nada et al. evaluated 10 wt.% DySZ as a temperature sensor over approximately 400–1000 °C, while Yang et al. demonstrated temperature sensing in APS YSZ:Dy sensor coatings over approximately 500–900 °C and through top coats up to 300 µm thick [3,11]. Heyes et al. established the basic principles of two-color phosphor thermometry for surface-temperature measurement [16].

Because Dy_2O_3 at high loadings can also contribute to the thermal-barrier composition of YSZ, Dy^{3+} occupies a distinctive position in considering sensing and thermal-barrier functions together. However, the data set used here does not provide a low-concentration PL-peak optimization for Dy^{3+}.

2.8. Literature basis for stress, crack, and delamination monitoring with rare-earth-doped YSZ

The smart-TBC concept should not be reduced to temperature measurement alone. TBC damage commonly develops through thermal-expansion mismatch, TGO growth, sintering, phase transformation, and local stress concentrations. These processes promote microcrack growth, interfacial delamination, and eventual top-coat spallation [1]. A truly smart coating would therefore benefit from providing an indicator of mechanical integrity in addition to temperature information.

In photoluminescence piezospectroscopy, the peak wavelength or wavenumber of an optical transition changes with stress because of crystal-field and elastic-strain effects. Once calibrated, the emission-peak shift can serve as a stress indicator. The fact that residual-stress distribution and its evolution during thermal cycling have been measured in Eu^{3+}-doped 8YSZ using this approach [20] shows that optically active ions in YSZ can carry mechanical information.

The mechanism can differ for crack and delamination detection. A crack or separated interface can alter the reflection/scattering paths of excitation and emission light and produce high contrast in luminescence intensity. Demonstration of delamination using YSZ:Eu sublayers [17], monitoring of early-stage subcritical delamination-crack growth in Er^{3+}/Yb^{3+}-doped YSZ by up-conversion luminescence imaging [18], and experimental/model-based quantification of delamination contrast in Er^{3+}-based layers [19] support the applicability of this mechanism.

Existing studies show that stress and delamination can be monitored by optical methods [17–20]. The evidence is not equally distributed among the candidates: strong direct evidence for stress and delamination is available for Eu^{3+}, while related/partial evidence for delamination is available for the Er^{3+} family. Comparable SHM calibrations for Tm^{3+}, Ho^{3+}, Nd^{3+}, and Dy^{3+} are not available in the selected source set.

2.9. Rationale for prioritizing Tm^{3+} in experimental work

For Tm^{3+}, a distinct PL maximum near 0.50 mol%, blue emission near 458 nm under 356 nm excitation, and a broad tested concentration range of 0.2–3.0 mol% have been reported [5]. Once the full ordinates are digitized, this broad concentration range will allow the concentration-quenching curve to be modeled.

These features justify prioritizing Tm^{3+} in comparative experiments performed under identical conditions [5]. However, because the Ho^{3+} and Nd^{3+} studies used different excitation powers, optical collection systems, specimen thicknesses, and crystal structures, the absolute brightness of the candidates cannot be compared directly across the existing studies.

RE_2O_3-equivalent mol% was adopted as the common notation for concentration comparisons. Values reported directly as RE_2O_3 for Tm, Ho, and Nd were retained unchanged; 1.5 mol% $ErO_{1.5}$ was converted stoichiometrically to 0.75 mol% Er_2O_3-equivalent. No reliable PL-peak mol% conversion was performed for Dy data reported in wt.% or host-composition form, and these values were not compared on the same numerical axis.

Table 1. Main literature reference data included in the MATLAB record structure.

Ion / key source	Concentration / PL evidence	High-temperature evidence	SHM / damage evidence	Role in this study
Tm^{3+} [5]	0.2–3.0 mol% Tm_2O_3; PL peak ~0.50 mol%; 356/458 nm	Sensor calibration missing in the turbine window	No direct evidence in the selected set	PL / quenching reference
Ho^{3+} [6,7]	Ho_2O_3; two separate studies; PL peaks ~0.75 and ~0.50 mol%	Thermometry calibration missing in the turbine window	No direct evidence in the selected set	Key example of study-dependent PL peak

Ion / key source	Concentration / PL evidence	High-temperature evidence	SHM / damage evidence	Role in this study
Nd^{3+} [8]	0.30–1.50 mol% Nd_2O_3; PL peak ~0.75 mol%	Thermometry calibration missing in the turbine window	No direct evidence in the selected set	PL / Judd–Ofelt / quenching reference
Er^{3+} [9,10,18,19]	1.5 mol% $ErO_{1.5}$ = 0.75 mol% Er_2O_3-equivalent; not an optimum	1173–1423 K and 1223–1423 K thermal-history sensing	Related/partial delamination evidence [18,19]	High-T thermal history + delamination monitoring
Eu^{3+} [3,11,14,17,20]	Fixed compositions; YSZ:Eu and related Y_2O_3:Eu/YSZ evidence kept separate; no PL optimum	Direct YSZ:Eu: 299–1073 K; Y_2O_3:Eu/YSZ [3] retained as related optical-access evidence	Strong direct evidence for stress + delamination [17,20]	Thermometry + SHM reference
Dy^{3+} [3,11,16]	Fixed sensor/host compositions; some sources use wt.%; no common mol% PL-peak value	Approximately 673–1273 K; in-situ thermometry	No direct SHM calibration in the selected set	High-T in-situ thermometry reference

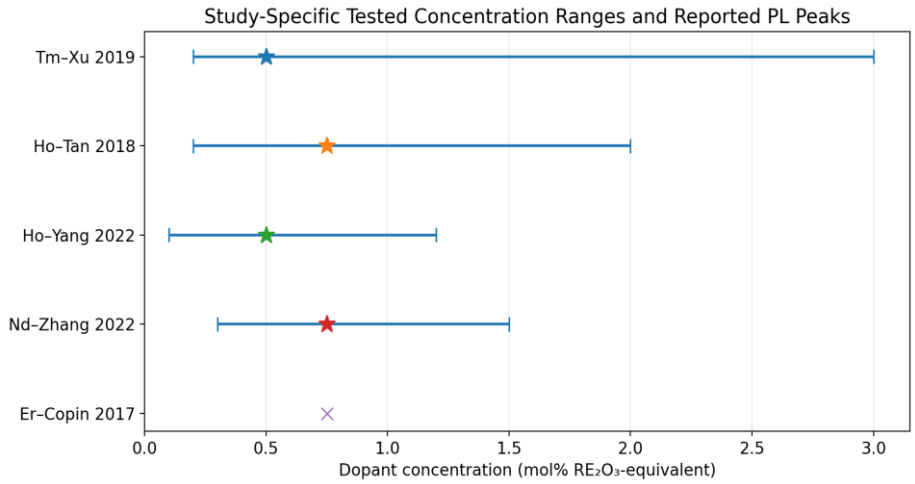

Figure 2. Tested dopant concentration ranges and reported photoluminescence peak positions for the selected studies, shown on an RE_2O_3-equivalent mol% basis. The Er^{3+} entry, 1.5 mol% $ErO_{1.5}$ = 0.75 mol% Er_2O_3-equivalent, is a fixed-composition high-temperature study and not a concentration optimum.

3. Computational Method

3.1. DOI-traceable records and data classes

Each experimental study is stored as an independent record in the MATLAB framework. The record includes study identity, ion, DOI, host phase, synthesis/coating method, concentration range, PL peak value, excitation/emission wavelengths, valid temperature range, measurement mode, and, where available, the concentration-quenching mechanism. This structure prevents data from different processes from being combined inadvertently into a single "virtual material."

The computational framework uses four main quantitative data groups: (i) concentration-dependent luminescence intensity I(c), (ii) fluorescence intensity ratio FIR(T), (iii) fluorescence lifetime τ(T), and (iv) thermal conductivity k(c,T). Temperature-sensing modes are also separated into "in-situ

thermometry" and "thermal-history sensing." A thermal-history data set is not assumed to provide the FIR(T) or τ(T) calibration required for in-situ thermometry.
Two additional data groups were defined for SHM assessment: (v) stress/strain-dependent optical peak shift or piezospectroscopic sensitivity and (vi) crack/delamination luminescence contrast. They were not included in the current QPI/PSO calculation because sufficiently complete and comparable data are not available for the six candidates.

3.2. Data-sufficiency check

The reference data-sufficiency criterion requires at least four I(c) points, at least four FIR(T) or τ(T) points compatible with the target measurement mode, and at least six k(c,T) points. Thermal-conductivity data are also expected to cover at least two temperatures and three concentration levels, while the measurement mode must be compatible with the intended application:

$$G = (N_I \geq 4) \wedge [(N_{FIR} \geq 4) \vee (N_\tau \geq 4)] \wedge (N_k \geq 6) \wedge (N_{T,k} \geq 2) \wedge (N_{c,k} \geq 3) \wedge (M_{mode} = 1) \quad (1)$$

These thresholds are not physical constants; they are data-sufficiency criteria intended to make curve fitting and candidate comparison minimally identifiable under sparse-literature conditions. Threshold sensitivity was examined using relaxed (3/3/3/4), reference (4/4/4/6), and strict (5/5/5/9) scenarios.
The engineering temperature window for the turbine application was defined as T_{gate} = 1200–1500 K. The fraction of a source range overlapping this window is expressed as $C_T = 100 \cdot \Delta T_{overlap}/300$. C_T quantifies only temperature-range overlap and does not make different measurement modes equivalent.

3.3. Optical response models

For two thermally coupled luminescence levels, the fluorescence intensity ratio can be written in Boltzmann form:

$$FIR(T) = B \cdot \exp[-C_2 \Delta E/T], \quad C_2 = hc/k_B = 1.438776877\ K \cdot cm \quad (2)$$

The corresponding relative temperature sensitivity is:

$$S_r(T) = (100/FIR) \cdot (dFIR/dT) = 100 \cdot C_2 \Delta E/T^2 \quad [\% \cdot K^{-1}] \quad (3)$$

A positive, single-peaked surrogate model was used to represent concentration quenching:

$$I(c) = A \cdot c \cdot \exp[-(c/c_q)^m] \quad (4)$$

Here, c is the dopant concentration, c_q is the characteristic concentration scale, m is the exponent controlling the post-peak decay, and A is the amplitude parameter. The analytical peak position is obtained from $c_{peak} = c_q \cdot m^{(-1/m)}$. The fitted peak is compared with the reference PL peak reported in the same source.

3.4. Thermal surrogate model and multi-criteria quality-performance index

When sufficient k(c,T) and optical data are available, MATLAB fits a low-order concentration–temperature surrogate model. Model parameters are required to be derived from source-verified experimental data rather than assumed constants.
For a future data-complete stage, the basic multi-criteria quality-performance index (QPI) combines normalized temperature sensitivity for the target measurement mode, luminescence intensity, lifetime, the contribution of low thermal conductivity, and evidence quality:

$$QPI = w_1 S_T^* + w_2 I^* + w_3 \tau^* + w_4 (1 - k^*) + w_5 E \quad (5)$$

For Eq. (5), nominal weights were defined as $w_1 = 0.25$, $w_2 = 0.30$, $w_3 = 0.15$, $w_4 = 0.20$, and $w_5 = 0.10$. Because the data-sufficiency criteria are not satisfied, these weights do not produce a material ranking in the present study. Weight sensitivity and ranking stability should be tested at the data-complete stage.
A robustness score that penalizes uncertainty is defined as:

$$R(c) = (1/N_T) \cdot \Sigma_i\ QPI(c,T_i) - \lambda \cdot \sigma_{QPI}(c) \quad (6)$$

In the present study, λ is not an active physical parameter; it should be evaluated by sensitivity analysis at the data-complete stage.

3.5. Particle swarm optimization

For concentration optimization, the classical PSO update follows the approach of Kennedy and Eberhart [12]:

$$v_i(t+1) = \omega v_i(t) + c_1 r_1[p_i - x_i(t)] + c_2 r_2[g - x_i(t)], \quad x_i(t+1) = x_i(t) + v_i(t+1) \tag{7}$$

In the current MATLAB implementation, 50 particles and 150 iterations were defined, with $\omega = 0.90 \rightarrow 0.35$, $c_1 = 1.70$, $c_2 = 1.90$, and a maximum particle velocity equal to 18% of the allowed concentration range. Because the system-level data-sufficiency gate was not passed, these settings do not affect the physical results reported here.

3.6. Proposed extended metrics for structural health monitoring

One of the most direct optical quantities for stress sensing is the sensitivity of the emission-peak position to stress. The piezospectroscopic sensitivity that should be calibrated in future for the same ion and coating can be expressed as:

$$S_\sigma = \partial\lambda_p/\partial\sigma \tag{8}$$

where λ_p is the selected emission-peak wavelength and σ is the mechanical/thermal stress. To generate a stress map, the effect of temperature on the spectral peak must be separated from the stress contribution.

For cracks or delamination, the optical contrast can, for example, be defined as:

$$C_d = (I_d - I_0)/I_0 \tag{9}$$

where I_d is the luminescence intensity in the damaged region and I_0 is the intensity in the intact reference region. This metric depends on delamination geometry, sensing-layer depth, scattering, porosity, and optical collection geometry; experimental calibration is therefore required for each coating architecture [17–19].

When sufficient data are available, the extended quality index including structural health monitoring can be written as:

$$QPI_{SHM} = w_1 S_T^* + w_2 I^* + w_3 \tau^* + w_4(1 - k^*) + w_5 S_\sigma^* + w_6 C_d^* + w_7 E \tag{10}$$

Equation (10) was not used in this study to generate a material ranking. The weights w_1–w_7 are to be redefined in future for the extended SHM index; the nominal five-weight set in Eq. (5) was not transferred directly to Eq. (10). The purpose is to define explicitly which measurable quantities must be obtained from future experiments.

Table 2. Data-sufficiency threshold sensitivity and nominal QPI/PSO settings. QPI and PSO are inactive in the present results.

Category	Parameter	Value
Threshold sensitivity	Relaxed N_I / N_{FIR} / N_τ / N_k	3 / 3 / 3 / 4
Threshold sensitivity	Reference N_I / N_{FIR} / N_τ / N_k	4 / 4 / 4 / 6
Threshold sensitivity	Strict N_I / N_{FIR} / N_τ / N_k	5 / 5 / 5 / 9
Threshold sensitivity	Min. T × c (relaxed / ref. / strict)	2×2 / 2×3 / 3×3
Data-sufficiency check	Current system outcome	PSO not applied in any of the three scenarios
QPI	Nominal weights (inactive)	0.25 / 0.30 / 0.15 / 0.20 / 0.10
PSO	Particles / iterations	50 / 150
PSO	Inertia weight	0.90 → 0.35
PSO	c_1 / c_2	1.70 / 1.90
PSO	v_{max}	0.18 × search range

4. Results

4.1. Study-specific concentration evidence

The verified record shows that the PL peak concentration is not a universal material constant independent of experimental conditions. Peak values of approximately 0.50 mol% for Tm^{3+} [5], 0.75 mol% [6] and 0.50 mol% [7] for Ho^{3+}, and approximately 0.75 mol% for Nd^{3+} [8] have been reported. Because a fixed composition was used in the high-temperature Er^{3+} studies, the 1.5 mol% Er value was not interpreted as an "optimum" [9,10].

The reported peak concentrations for Tm^{3+}, Ho^{3+}, and Nd^{3+} fall within a similar low-mol% range; however, they were obtained using different host phases, excitation conditions, and optical setups. In addition, the Nd^{3+} data are based on up-conversion luminescence, whereas the Tm^{3+} and Ho^{3+} values originate from different photoluminescence measurement conditions. These differences were taken into account by treating the peak concentrations as source-specific reference values.

4.2. Spectral behavior and concentration quenching

Tm^{3+} produces blue emission near 458 nm, while Ho^{3+} produces strong green emission near 551–553.5 nm [5–7]. The Nd^{3+} study includes up-conversion luminescence and Judd–Ofelt analysis [8]. Different spectral regions impose different requirements on the laser/LED source, optical filters, and detector. System design should therefore consider the applicability of the optical hardware in the turbine environment as well as the material itself.

Concentration quenching is a physical design constraint. As dopant content increases, the signal initially strengthens because the number of optically active centers increases; beyond a certain level, however, energy transfer and ion–ion interactions increase non-radiative losses and reduce luminescence. Accordingly, the assumption that "more rare earth = a better sensor" is not valid. A separate I(c) curve is required for each ion.

4.3. High-temperature evidence and turbine relevance

The selected Er^{3+} thermal-history data have been demonstrated over 1173–1423 K [9] and 1223–1423 K [10], providing substantial overlap with the 1200–1500 K engineering window. The selected upper limit of the direct YSZ:Eu in-situ thermometry evidence is approximately 1073 K [11,14], whereas for Dy^{3+} it is approximately 1273 K [3,11,16]. Because the Y_2O_3:Eu/YSZ system of Abou Nada et al. [3] uses a different host architecture, it was not included in the Eu^{3+} C_T calculation and was retained separately as related coating-scale optical-access evidence.

When only temperature-range overlap with the 1200–1500 K window is considered, Er^{3+} provides approximately 74% coverage in thermal-history mode and Dy^{3+} approximately 24% in in-situ mode. The selected Eu^{3+} in-situ evidence lies below this window. These percentages are not a material ranking of the form "Er is better than Dy"; they quantify only the valid temperature ranges of different measurement modes.

4.4. Numerical preparation and Ho^{3+} curve-fitting test

Six concentration–intensity points from the Ho^{3+} series of Yang et al. [7] were digitized from the published graph and used with Eq. (4) for curve fitting and peak-position reproduction. Full ordinate digitization has not yet been completed for Tm^{3+} and Nd^{3+}, so the same test was not applied to those two candidates.

4.4.1. Curve-fitting test for Yang et al. Ho^{3+} data

The highest emission-peak values in the 530–565 nm green band were approximately digitized from Figure 10 of Yang et al. [7] for Ho_2O_3 concentrations of 0.10, 0.30, 0.50, 0.75, 1.00, and 1.20 mol%. After normalizing the 0.50 mol% sample to $I/I_{max} = 1$, the resulting values were 0.470, 0.707, 1.000, 0.765, 0.586, and 0.441, respectively.

Nonlinear least-squares fitting of Eq. (4) to these six points yielded A = 4.595, c_q = 0.533 mol%, and m = 1.139. The global fit gave R^2 = 0.874 and RMSE = 0.068. The analytical peak was c_{peak} = 0.475 mol%; relative to the literature peak of 0.50 mol%, the absolute peak error was 0.025 mol% and the relative error, at the displayed precision, was approximately 5.0%.

Table 3. Ho^{3+} concentration–PL data approximately digitized from Figure 10 of Yang et al. [7] and the Eq. (4) fit.

Ho_2O_3 (mol%)	Digitized I/I_{max}	Eq. (4)	Residual (measurement − model)
0.10	0.470	0.396	+0.074
0.30	0.707	0.819	−0.113
0.50	1.000	0.906	+0.094
0.75	0.765	0.787	−0.022
1.00	0.586	0.592	−0.006
1.20	0.441	0.443	−0.002

When the Dexter transformation reported by Yang et al. was repeated for the high-concentration points, the regression slope was approximately −1.906, in good agreement with the source value of approximately −1.95. This independent check indicates that the graph digitization preserves the high-concentration quenching trend with reasonable accuracy.

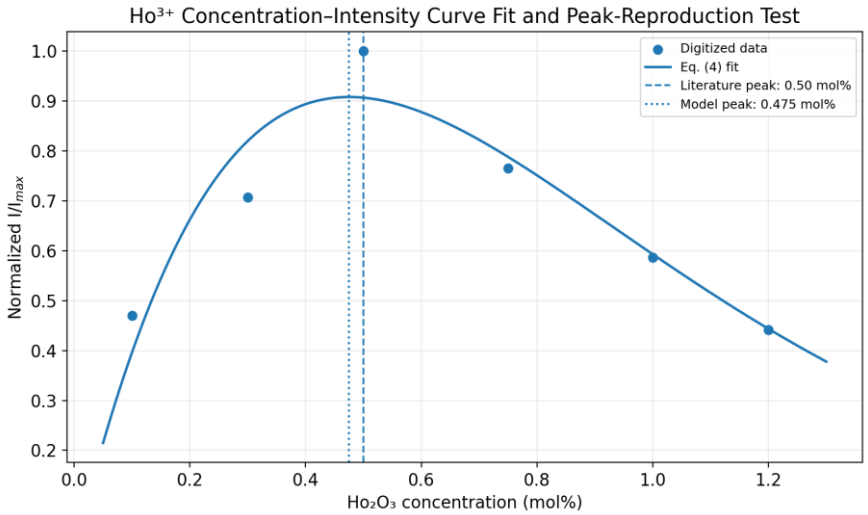

Figure 3. Curve-fitting and peak-position reproduction test for the Ho^{3+} concentration–luminescence data using Eq. (4). The model reproduces the literature peak of 0.50 mol% at 0.475 mol%; the result is useful as a peak-screening fit example but is not interpreted as independent model validation.

4.4.2. Data-sufficiency threshold sensitivity

The Yang et al. [7] Ho^{3+} series satisfies the concentration-point criterion under the relaxed, reference, and strict scenarios. However, system-level QPI/PSO analysis was not performed because sufficiently complete high-temperature optical calibration and sensor-regime k(c,T) data are not available together for the same system.

This result shows that the decision not to apply QPI/PSO does not depend solely on the reference threshold values; the same data gaps persist under reasonable changes in threshold stringency.

4.5. Comparison of available and missing evidence

Comparison of the six ions shows marked differences in evidence coverage. Concentration–photoluminescence references are available for Tm^{3+}, Ho^{3+}, and Nd^{3+}, whereas turbine-window thermometry and direct SHM calibration are missing in the selected source set. Er^{3+} has high-temperature thermal-history and delamination evidence; Eu^{3+} has stress and delamination evidence; and Dy^{3+} has more extensive in-situ thermometry evidence.

Table 4. Comparison of available and missing evidence for the six candidates. N/A indicates that no data are available in the relevant temperature range, whereas 0% indicates that data exist but do not overlap the 1200–1500 K window. “SHM evidence” refers to direct or related optical measurement of stress or delamination within the same ion family and does not imply that all data groups correspond to the identical composition and process.

Activator	I(c) reference	1200–1500 K coverage C_T	Direct low-c k(c,T)	Related SHM evidence	Dominant evidence mode
Tm^{3+}	Available	N/A (no high-T data)	No	No	PL
Ho^{3+}	Available	N/A (no high-T data)	No	No	PL
Nd^{3+}	Available	N/A (no high-T data)	No	No	PL
Er^{3+}	No concentration optimum	~74%	No	Related/partial; delamination [18,19]	Thermal history + SHM
Eu^{3+}	No concentration optimum	0% (direct YSZ:Eu evidence below 1200 K)	No	Strong direct; stress + delamination [17,20]	In-situ thermometry + SHM
Dy^{3+}	No concentration optimum	~24%	No	No direct evidence in selected set	In-situ thermometry

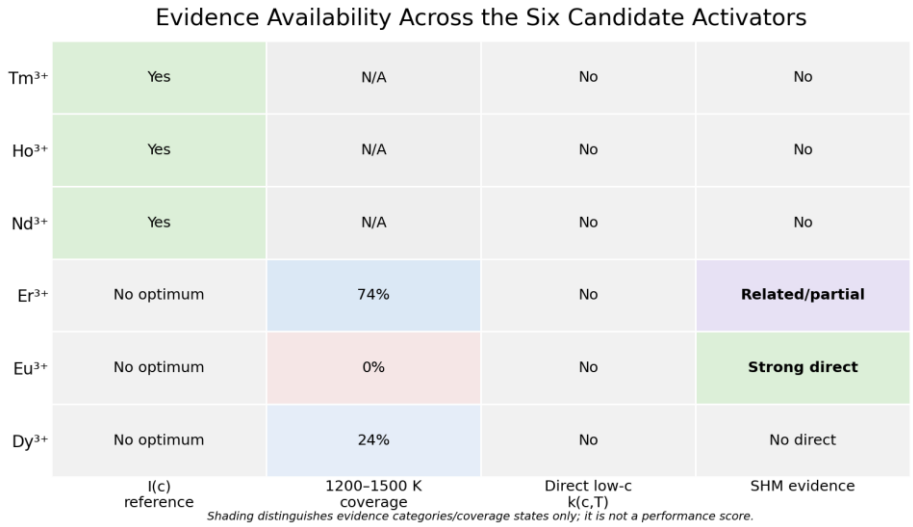

Figure 4. Visual summary of available and missing evidence for the six candidates. N/A indicates no data; 0% indicates that the available data do not overlap the 1200–1500 K window. SHM classes are the same as in Table 4. Cell shading is used only to distinguish evidence categories and coverage states; it is not a performance score.

5. Discussion

5.1. Assessment of the available evidence

Existing studies show that YSZ can serve as an optical host for different rare-earth ions and that measurable photoluminescence can be obtained at low dopant levels [5–8,14]. Because of concentration quenching, a higher dopant concentration does not always produce a stronger signal. Room-temperature PL behavior alone also does not represent high-temperature performance. Eu^{3+}-based stress and delamination studies, together with Er^{3+}/Yb^{3+}- and Er^{3+}-based delamination studies, show that the optical signal can be related to structural condition [17–20].

These findings support the addition of optical monitoring functionality to the thermal-protection role of a TBC. Continuous real-time multiparameter monitoring, however, has not yet been demonstrated for all six candidates on a rotating turbine blade under actual engine conditions in the 1200–1500 K range.

5.2. Complementary nature of the Tm^{3+}, Eu^{3+}, and Er^{3+} evidence

Tm^{3+} has distinct concentration–photoluminescence data [5]. Eu^{3+} has strong SHM evidence for stress and delamination [17,20]. Er^{3+} has high-temperature thermal-history data and delamination-monitoring studies [9,10,18,19]. These different evidence types show that no single ion can be assumed to be inherently superior for every function.

Two design strategies may be considered in future work. The first is a single-activator multifunctional coating in which one rare-earth ion provides both temperature and SHM functionality at an adequate level. The second is a multilayer sensor-TBC architecture in which the thermal-barrier top coat is separated from thin luminescent sublayers with different optical functions. The latter may be more realistic if an ion is optically effective but not ideal for the thermal-barrier role, or if different sensing functions require different ions [3,17–19].
Controlled experiments using the same production method and comparable microstructures are required to compare single-activator and multilayer architectures.

5.3. Missing data and conditions for applying PSO

Filling a missing data group with values measured for another ion or a different process could create artificial comparability among the candidates. Accordingly, unknown high-temperature optical response, stress sensitivity, or k(c,T) data were not transferred directly from other systems in this study. The data-sufficiency check was used to activate the multi-criteria calculation only when the required data groups are available together. Although the I(c) curve for Ho^{3+} reproduces the peak position with acceptable accuracy, high-temperature, thermal, and SHM data gaps remain.

5.4. Optical SHM mechanisms

Three main mechanisms are considered in the proposed optical SHM approach. The first is piezospectroscopic peak shift: stress alters the crystal field and changes the wavelength of specific luminescence transitions. After calibration, laser scanning can be used to generate a stress map at the surface or at a selected depth [20]. The second is luminescence-intensity contrast: cracks or delamination alter the optical path and can increase or decrease emission in the damaged region [17–19]. The third involves changes in lifetime and spectral ratio, which may be used together to help separate temperature and stress effects.
A single optical-intensity value is not sufficient for direct deformation measurement. Calibration between strain/stress and spectral peak position, an appropriate optical mapping geometry, and, when needed, finite-element-assisted mechanical reconstruction are required. SHM interpretation is therefore restricted to calibrated piezospectroscopic sensitivity and/or damage-contrast measurements.

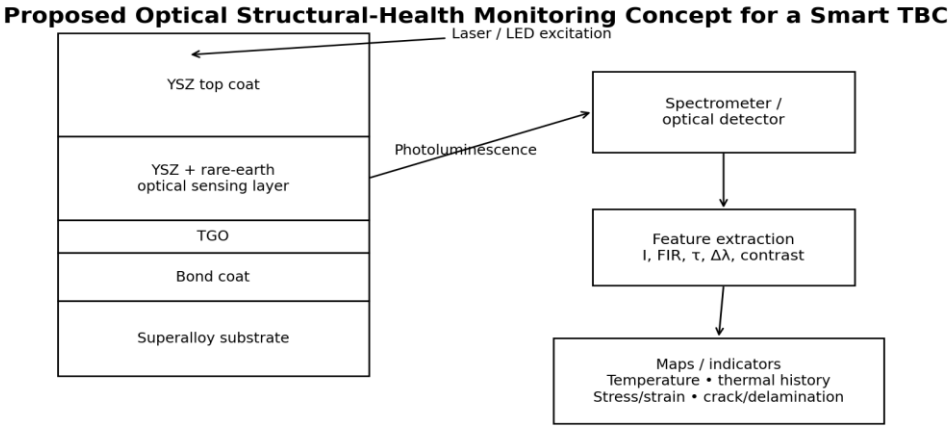

Figure 5. Proposed smart-TBC structural-health-monitoring concept. Optical excitation and photoluminescence acquisition can be converted, when suitable calibrations are available, into indicators of temperature/thermal history, stress, and crack/delamination.

6. Experimental Work Required for Full Optimization

Before a complete multi-criteria comparison can be performed, the missing data groups must be completed through targeted, mutually compatible experiments. The proposed experimental program is summarized below.

6.1. Experiment 1: Concentration–photoluminescence scan under identical conditions

The Tm^{3+}, Ho^{3+}, Nd^{3+}, Er^{3+}, Eu^{3+}, and Dy^{3+} candidates should, as far as possible, be prepared in the same YSZ host phase using the same production method. Denser concentration sampling should be performed

around the peak region reported for each candidate; for Tm^{3+}, this region is around 0.50 mol%. The same laser power, optical collection angle, specimen thickness, and detector settings should be used to obtain a genuine comparative optical-intensity data set across the candidates.

6.2. Experiment 2: High-temperature optical calibration over 1200–1500 K

The target measurement mode should be selected in advance for each candidate. For in-situ thermometry, FIR(T) or τ(T) should be calibrated; for thermal-history sensing, the relationship between permanent optical change and exposure temperature should be measured. High-temperature blackbody radiation, signal-to-noise ratio, and thermal quenching should also be reported.

6.3. Experiment 3: Stress/strain–photoluminescence calibration

Coating specimens should be subjected to controlled mechanical loading and/or thermal cycling. Spectral peak shift $\Delta\lambda_p$, linewidth, intensity, and lifetime changes should be measured simultaneously. The stress field should be validated by an independent method, such as XRD, digital image correlation where appropriate, or finite-element-assisted mechanical calibration. This experiment will make the S_σ value in Eq. (8) comparable among candidates.

6.4. Experiment 4: Controlled crack and delamination imaging

Delamination/crack regions with known size and location should be generated by Rockwell indentation, controlled interfacial defects, or thermal cycling. The contrast C_d between intact and damaged regions should be calculated from luminescence images, and the minimum detectable defect size should be established. The Eu^{3+} and Er^{3+} literature provides reference methods for this experiment [17–19]. Applying the same test to Tm^{3+} will determine whether its distinct emission near 458 nm offers an advantage for damage imaging.

6.5. Experiment 5: Thermal conductivity and coating durability in the sensor regime

The effects of low rare-earth additions on the thermal conductivity, phase stability, sintering behavior, and thermal-cycling life of YSZ should be measured within the same specimen family. k(c,T) should be determined at no fewer than two, preferably three, temperatures and at multiple concentrations. Optical performance should be evaluated together with the fundamental thermal-protection function of the TBC.

6.6. Experiment 6: Coating-scale and optical-access validation

Single-crystal data are valuable for screening but do not fully represent the scattering, porosity, and thickness effects of real TBC microstructures produced by APS, SPS, EB-PVD, or PS-PVD. The selected candidates should therefore be produced in realistic coating architectures, and top-coat thickness, luminescent-layer depth, and optical access should be evaluated systematically. Dynamic testing should then be performed at the hot-air-rig or burner-rig level.

Table 5. Proposed data package for six experimental stages followed by uncertainty analysis.

Stage	Quantity to be measured	Minimum objective	Role in PSO/QPI
1	I(c), spectrum, peak concentration	True optical comparison among ions in the same setup	I* and concentration range
2	FIR(T) or τ(T), 1200–1500 K	High-T thermometry / thermal-history validation	S_T*, τ*
3	$\Delta\lambda_p(\sigma)$ or equivalent	Stress/strain calibration	S_σ*
4	Damaged–intact luminescence image	Crack/delamination detection limit	C_d*
5	k(c,T), phase, and thermal cycling	Preservation of TBC function	(1 − k*), durability constraint
6	APS/EB-PVD/SPS coating-scale test	Real microstructure and optical access	Feasibility constraint
A	Repeat experiments and uncertainty assessment	Confidence interval and repeatability	E, Monte-Carlo / robust score

After this data package is completed, the MATLAB framework should fit the curves for each candidate, reproduce the literature reference peak values, and quantify uncertainties. Candidates satisfying the data-sufficiency criteria can then enter the extended QPI assessment; PSO may subsequently be applied to design variables such as dopant concentration and, where relevant, sensor-sublayer thickness. The final

stage should report weight sensitivity, bootstrap/Monte-Carlo uncertainty propagation, and PSO convergence.

7. Limitations

The main limitation of this study is the absence of a complete multiphysics data set collected under identical experimental conditions for all six candidates. Only one Ho^{3+} I(c) data set has been digitized and used in the curve-fitting test. The full ordinates of the Tm^{3+} and Nd^{3+} curves have not yet been digitized in the same manner. For Tm^{3+}, Ho^{3+}, and Nd^{3+}, high-temperature thermometry data within the turbine-relevant window are insufficient in the selected source set.

A second limitation is the unequal distribution of SHM evidence among the candidates. Strong direct evidence for stress and delamination is available for Eu^{3+}, while delamination-monitoring studies are available within the Er^{3+} family [18,19]. Comparable SHM calibrations are not available for Tm^{3+}, Ho^{3+}, Nd^{3+}, and Dy^{3+}.

A third limitation is the difference between single crystals and real coating microstructures. Porosity and scattering in APS coatings, the columnar structure of EB-PVD coatings, and the microstructure of SPS coatings can alter optical-signal access and mechanical behavior. The candidates therefore require additional coating-scale validation.

A fourth limitation is the presence of rotation, vibration, combustion radiation, surface contamination, optical-window durability, and line-of-sight constraints in actual engine environments. Accordingly, successful laboratory-scale in-situ optical measurement does not by itself imply readiness for continuous real-time monitoring in a flight engine.

8. Conclusions

7. The Tm^{3+}, Ho^{3+}, Nd^{3+}, Er^{3+}, Eu^{3+}, and Dy^{3+} systems were evaluated as separate sensor candidates; data from different studies were not merged into a single virtual-material data set.
8. Peak values of approximately 0.50 mol% for Tm^{3+}, approximately 0.50–0.75 mol% for Ho^{3+}, and approximately 0.75 mol% for Nd^{3+} are reported in the concentration–photoluminescence literature. For Tm^{3+}, the approximately 0.50 mol% value is a practical concentration reference for subsequent comparative experiments.
9. Er^{3+} provides strong evidence for high-temperature thermal-history sensing in the selected sources. Strong direct evidence for stress and delamination exists for Eu^{3+}, while experimental studies on delamination monitoring are available for the Er^{3+} family [17–20]. Dy^{3+} has broader high-temperature evidence for in-situ thermometry.
10. Curve fitting of the Ho^{3+} data of Yang et al. [7] yielded c_{peak} = 0.475 mol%, R^2 = 0.874, and RMSE = 0.068. This result shows that the peak position in the source graph can be reproduced; it is not interpreted as independent physical-model validation.
11. Because high-temperature FIR(T)/τ(T), low-dopant k(c,T), and candidate-specific SHM calibrations are not jointly available in the present data set, QPI/PSO-based material ranking was not performed.
12. The next stage should complete comparative PL measurements, high-temperature optical calibration, stress–peak-shift calibration, controlled crack/delamination imaging, thermal-conductivity measurements, and thermal-cycling tests using the same process and comparable coating architectures.

Declarations

Data and Code Availability: This study is based on a MATLAB computational framework and DOI-traceable study records. Six Ho^{3+} points approximately digitized from Figure 10 of Yang et al. [7] were used as normalized curve-fitting data. These are not raw spectrometer outputs, but relative ordinates approximately extracted from a published graph. The remaining high-temperature optical-response, SHM-calibration, and sensor-regime k(c,T) data groups should be digitized from verified sources or measured experimentally before a full comparison is undertaken.

Funding: This research received no external funding.

Conflict of Interest: The author declares no conflict of interest.

Appendix A. Next steps for data extraction and experiments

1. Six points from the Ho^{3+} I(c) series of Yang et al. [7] have been digitized and used with Eq. (4) for curve fitting and peak-position reproduction. The Ho^{3+} curve of Tan et al. [6] should be digitized as a separate study; the two Ho^{3+} series should not be merged into a single curve.
2. For Tm^{3+} and Nd^{3+}, concentration-dependent emission intensities should be digitized as complete curves, and the fitted peaks should be tested for reproduction of the literature reference values of approximately 0.50 and 0.75 mol%, respectively.
3. FIR(T) or τ(T) data should be generated experimentally for the candidates over 1200–1500 K.
4. For at least Tm^{3+}, Eu^{3+}, and Er^{3+}, stress-induced peak shift and controlled delamination/crack luminescence contrast should be measured using the same coating process.
5. Optical and thermal studies should be matched as closely as possible in terms of host phase and process to obtain k(c,T) data. If matching is not possible, a study-compatibility penalty should be applied.
6. Before material ranking, QPI weight sensitivity, bootstrap/Monte-Carlo uncertainty propagation, and PSO convergence tests should be performed.

ÖZET
Türkiye'de ve dünyadaki birçok deprem ülkesinde, yumuşak kat düzensizliğinin sebep olduğu yıkımlar ve ekonomik kayıplar halen ön sıralarda yer almaktadır. Çoğunlukla katlar arası önemli rijitlik farklarına sebep olan çeşitli mimari uygulamalar ile oluşan bu düzensizlik türü, deprem sonrası hasarların ilgili katta yoğunlaşarak büyük kalıcı yanal ötelemelere veya kat mekanizması ile göçmelere sebep olmaktadır. Özellikle dolgu duvarların sebep olduğu yumuşak kat düzensizliklerinde geleneksel doğrusal tasarım yaklaşımları söz konusu riskleri belirlemede yetersiz kalmaktadır. Bu nedenle yumuşak kat düzensizliği bulunan birçok binanın ileri yöntemlerle değerlendirilmesine ve gerekli durumlarda güçlendirilmesine ihtiyaç bulunmaktadır. Hasarın belirli bir katta yoğunlaştığı bu tür binalarda geleneksel güçlendirme yöntemlerinin kullanılması çoğu zaman pratik ve ekonomik olmamaktadır. Buna karşılık binadaki sönümü artırmayı hedefleyen viskoz sıvılı sönümleyici (VSS) cihazlar ile güçlendirme bölgesel güçlendirmeler için önemli bir potansiyele sahiptir. Bu çalışmada, betonarme bir bina modeli üzerinde yumuşak kat göçmesinin VSS'ler ile önlenebilirliği sayısal olarak incelenmiştir. Bunun için deprem yönetmeliğine uygun olarak tasarlanmış 4-katlı bir bina modeli ele alınmış ve zemin katındaki dolgu duvarların azaltılması ve kat yüksekliğinin artırılması suretiyle yumuşak kat düzensizliği oluşturulmuştur. Daha sonra bina modeli, sadece birinci katında bazı açıklıklara VSS'ler uygulanarak güçlendirilmiştir. Güçlendirme öncesi ve sonrası modeller, en büyük deprem yer hareketi düzeyine göre ölçeklenen uzak ve yakın fay karakteristiğine sahip iki grup deprem kaydı için doğrusal olmayan dinamik analiz ile performans-esaslı yaklaşım çerçevesinde değerlendirilmiştir. Çalışmada maksimum ve kalıcı göreli kat öteleme oranları ve plastik dönmelere ait talep/kapasite oranları incelenmiştir. Uzak fay grubundaki kayıtlar için oluşan tüm göçme durumları VSS'ler sayesinde önlenebilirken, yakın fay grubuna ait bazı kayıtlarda VSS kapasiteleri artırılmasına rağmen göçme oluşumu engellenememiştir. VSS kullanımı, yumuşak kat düzensizliği bulunan kattaki maksimum ve kalıcı göreli kat öteleme oranlarını azaltarak uzak fay grubundaki depremler için hasarları *Göçmenin Önlenmesi* performans düzeyine çekebilmiş, ancak yakın fay depremlerinde ise hasarlar bir üst katta yoğunlaşmış ve öngörülen performans düzeyi sağlanamamıştır.
Anahtar kelimeler: Yumuşak kat düzensizliği, Göçmenin Önlenmesi, Vizkoz sıvılı sönümleyici, Betonarme bina, Performans-esaslı sismik değerlendirme

ABSTRACT
Soft-story irregularity remains one of the major causes of structural collapse and associated economic losses in Türkiye and other earthquake-prone regions worldwide. This type of vertical irregularity commonly results from architectural and functional requirements that produce a substantial difference in lateral stiffness between adjacent stories. During strong earthquakes, deformation and damage can consequently become concentrated in the soft story, leading to large permanent lateral displacements and, in severe cases, a story-level collapse mechanism. This vulnerability may not be adequately identified by conventional linear design approaches, particularly in buildings where the soft-story condition is primarily associated with reduced infill walls. Therefore, advanced performance-based assessment and, where necessary, effective retrofit strategies are required for such buildings. Conventional strengthening methods may be impractical or uneconomical when damage is highly

localized in a particular story. In contrast, fluid viscous dampers (FVDs), which enhance supplemental energy dissipation, may provide an efficient alternative for localized seismic retrofit. This study numerically investigates the feasibility of preventing soft-story collapse in a reinforced concrete building using FVDs. A four-story reinforced concrete building designed in accordance with the seismic design provisions was considered as the reference structure. A soft-story irregularity was subsequently introduced at the ground story by reducing the amount of infill walls and increasing the story height. The resulting structure was then retrofitted by installing FVDs in selected bays of the ground story only. The unretrofitted and retrofitted models were evaluated using nonlinear response-history analyses under two groups of ground motions representing far-fault and near-fault earthquake characteristics, scaled to the maximum considered earthquake level. The seismic performance was assessed in terms of maximum and residual interstory drift ratios and plastic rotation demand-to-capacity ratios. The results indicate that all collapse cases observed under the far-fault ground-motion group could be prevented by the use of FVDs. However, collapse could not be prevented for some of the near-fault ground motions even when the damper capacities were increased. For the far-fault records, the FVDs substantially reduced both maximum and residual interstory drift ratios in the soft story and shifted the structural damage level to the Collapse Prevention performance level. For the near-fault records, however, the reduction in deformation demand at the soft story was accompanied by a redistribution of damage toward the story immediately above it, and the target performance level could not be consistently achieved.
Keywords: Soft-story irregularity; Collapse Prevention; Fluid viscous dampers; Reinforced concrete buildings; Performance-based seismic assessment

GİRİŞ

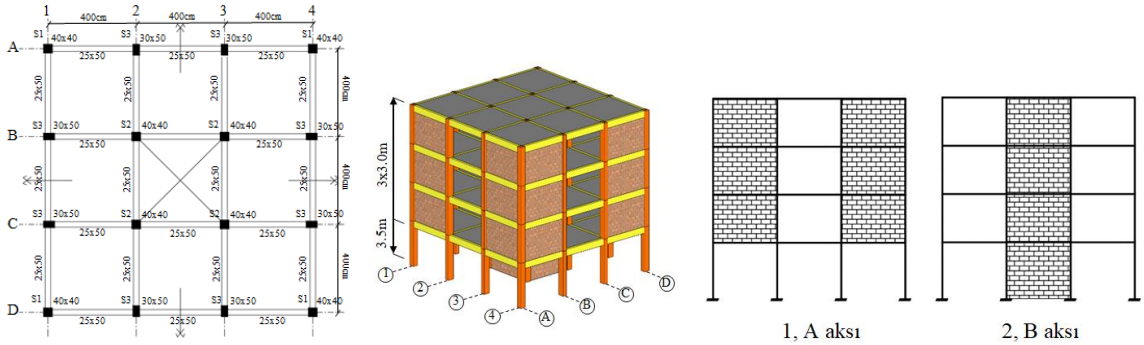
Yumuşak kat düzensizliği, özellikle zemin katta dolgu duvarların azaltılması veya kaldırılması ve kat yüksekliğinin artırılması gibi mimari uygulamalar sonucunda oluşan önemli bir düşey düzensizlik türüdür. Katlar arasındaki yatay rijitlik ve dayanım farkının artması, deprem etkisi altında deformasyonların düzensizliğin bulunduğu katta yoğunlaşmasına ve ileri hasar durumunda kat mekanizmasıyla göçmeye neden olabilmektedir. Türkiye'de 1999 Kocaeli ve Düzce depremleri ile 2023 Kahramanmaraş depremlerinde gözlenen ağır hasar ve göçmeler, zemin kat düzensizliklerinin deprem güvenliği açısından önemli bir sorun oluşturduğunu göstermiştir (Erdik, 2000; AFAD, 2023). Dolgu duvarların yapı davranışına etkisini inceleyen çalışmalar da bu tür rijitlik farklılıklarının yumuşak kat mekanizmasını belirgin biçimde etkileyebildiğini ortaya koymaktadır (Dolšek & Fajfar, 2001; Fardis & Panagiotakos, 1997). Benzer şekilde, farklı yumuşak kat oluşum biçimlerinin betonarme yapıların sismik davranışı üzerindeki etkisi sayısal olarak da gösterilmiştir (Özmen vd., 2020).

Şekil 1. Yumuşak kat nedeniyle oluşan göçme örnekleri (AFAD, 2023)

Yumuşak kat oluşumundaki temel problem, deprem sırasında yatay ötelenme ve plastik şekil değiştirmelerin belirli bir katta yoğunlaşmasıdır. Özellikle güçlü yer hareketlerinde bu durum kat mekanizmasına ve nihai olarak göçmeye dönüşebilmektedir. Bu nedenle yumuşak katlı yapıların değerlendirilmesinde yalnızca dayanım kontrollerinin değil, deprem taleplerinin deformasyon ve hasar düzeyleri açısından da incelendiği performans esaslı yaklaşımların kullanılması önemlidir.

Yumuşak katlı yapıların güçlendirilmesinde kolon mantolama, perde, çerçeve ekleme veya çapraz çelik çaprazlar ekleme gibi geleneksel yöntemler kullanılabilmektedir. Ancak bu yöntemler yapının rijitlik ve dayanım dağılımını önemli ölçüde değiştirebilmekte, mimari kullanımın kısıtlanmasına veya yapının diğer bölümlerinde ilave müdahalelere neden olabilmektedir. Bu nedenle, deprem enerjisinin taşıyıcı sistem yerine, ilave enerji tüketim elemanları aracılığıyla sönümlenmesini sağlayan pasif kontrol sistemleri önemli bir alternatif oluşturmaktadır (Symans vd., 2008). Bunlar arasında önemli yer tutan viskoz sıvılı sönümleyiciler (VSS), hıza bağlı sönüm kuvveti oluşturarak yapıya önemli enerji tüketme kapasitesi kazandırabilmekte ve mevcut taşıyıcı elemanlarda kapsamlı değişiklik yapılmadan sismik taleplerin karşılanmasına olanak sağlamaktadır.

Yumuşak katlı betonarme yapıların enerji tüketen sistemlerle güçlendirilmesine yönelik çalışmalar, bu yaklaşımın özellikle kat öteleme ve plastik şekil değiştirme taleplerinin azaltılmasında etkili olabileceğini göstermektedir. Benavent-Climent ve Mota-Páez (2017) ile Oinam ve Sahoo (2018), yumuşak birinci kata sahip betonarme çerçevelerde pasif enerji tüketen sistemlerin kullanımının sismik performansı iyileştirebildiğini göstermiştir. Jara vd. (2020) ise 19 Eylül 2017 Mexico City depreminde gözlenen yumuşak katlı betonarme bina hasarlarını incelemiş ve mevcut ilk katı yumuşak yapıların güçlendirilmesinde enerji tüketen sistemlerin kullanımını değerlendirmiş ve çeşitli sistemlerin performanslarını karşılaştırmıştır. Çakıl vd. (2026), yumuşak kat düzensizliği bulunan betonarme yapılarda farklı güçlendirme yöntemlerini karşılaştırmış ve viskoz sönümleyicilerin yapısal taleplerin azaltılmasındaki etkinliğini diğer güçlendirme seçenekleriyle birlikte değerlendirmiştir.

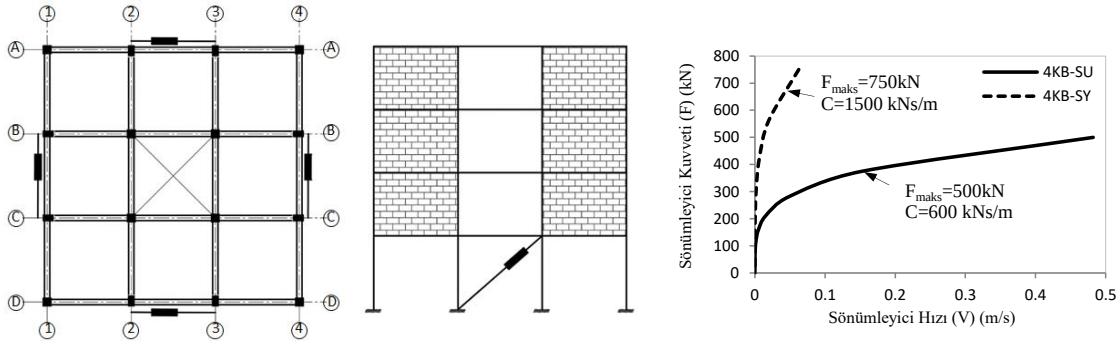


Bununla birlikte, yumuşak katlı bir yapıda sönümleyicilerin yalnızca düzensizliğin bulunduğu kata yerleştirilmesi, deformasyon taleplerinin üst katlara aktarılmasına neden olabilmektedir. Ayrıca yakın fay hareketlerinde görülebilen yüksek hız darbeleri ve farklı enerji içerikleri, yapının ve enerji tüketim sisteminin davranışını uzak fay kayıtlarından farklılaştırabilmektedir. Yumuşak birinci kata sahip betonarme çerçevelerin enerji tüketen sistemlerle güçlendirilmesini yakın fay depremleri altında inceleyen çalışmalar da bu farklılığın dikkate alınması gerektiğini göstermektedir (Mota-Páez vd., 2021). Dolayısıyla VSS kullanımının yumuşak kat göçmesini önlemedeki etkinliğinin farklı deprem karakteristikleri altında ve yapı genelindeki performans dikkate alınarak değerlendirilmesi önem taşımaktadır.

Bu çalışmada, TBDY-2018'e göre tasarlanan dört katlı bir betonarme binada oluşturulan yumuşak kat düzensizliğinin VSS'ler ile giderilerek *Göçmenin Önlenmesi* performans düzeyinin sağlanabilirliği, yakın fay ve uzak fay karakteristiğine sahip deprem kayıtları altında incelenmiştir. Yumuşak kat, zemin kattaki dolgu duvarların azaltılması ve kat yüksekliğinin artırılmasıyla oluşturulmuş ve VSS'ler yalnızca birinci kattaki seçilmiş açıklıklara yerleştirilmiştir. Güçlendirme öncesi ve sonrası bina modellerinin doğrusal olmayan dinamik analizleri TBDY-2018 kapsamında değerlendirilmiş, maksimum ve kalıcı göreli kat öteleme oranları ile plastik dönme talep/kapasite oranları kullanılarak en büyük deprem yer hareketi düzeyi için *Göçmenin Önlenmesi* performans düzeyinin sağlanabilirliği araştırılmıştır.

SAYISAL İNCELEME

İncelenen Bina Modeli ve Tasarım Özellikleri



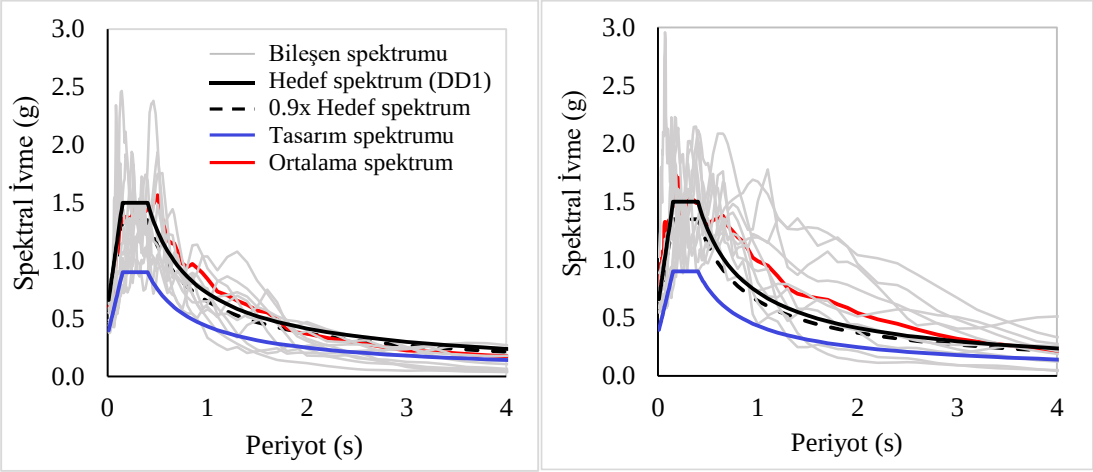
Çalışmada, yumuşak kat düzensizliği nedeniyle oluşan *Göçmenin Önlenmesi*nde viskoz sıvılı sönümleyicilerin (VSS) etkinliğini incelemek amacıyla dört katlı bir bina modeli ele alınmıştır. İncelenen bina modelinin üç boyutlu görünümü, tipik kat planı ve dolgu duvar düzeni Şekil 2'de gösterilmiştir. Yumuşak kat davranışını temsil etmek amacıyla zemin katın özellikleri üst katlardan farklılaştırılmıştır. Bu kapsamda, zemin kat yüksekliği artırılmış ve bu katta bulunan dolgu duvarların bir bölümü kaldırılmıştır. Böylece komşu katlar arasında yatay rijitlik ve deformasyon kapasitesi bakımından belirgin bir farklılık oluşturularak deprem etkisi altında deformasyonların zemin katta yoğunlaşmasına elverişli bir taşıyıcı sistem elde edilmiştir. Bina, kullanım amacı konut olarak alınmış, yüksek süneklik sınıfını sağlayacak şekilde 2007 Türkiye Deprem Yönetmeliğine göre tasarlanmıştır (Bayındırlık ve İskân Bakanlığı, 2007). Tasarımda dolgu duvarların ağırlıkları göz önüne alınmış, rijitlik ve kapasiteleri ihmal edilmiştir. Tasarım sonuçlarına ait detaylı bilgi Aşıcı (2025)'de bulunabilir.

Şekil 2. Bina tipik kat planı, üç boyutlu görünümü ve dolgu duvar düzenleri

Doğrusal Olmayan Sayısal Modelleme ve Analiz Özellikleri

Çalışmada güçlendirme öncesini temsil eden bir model (4KB) ve VSS'ler ile güçlendirilmiş binaları temsilen iki model oluşturulmuştur. VSS'ler sadece zemin katta ve kenar akslardaki orta açıklıklara uygulanmıştır (Şekil 3). VSS'ler hız bağımlı sönüm kuvveti oluşturan doğrusal olmayan kuvvet–hız bağıntısı kullanılarak modellenmiştir. Uzak ve yakın fay grubundaki kayıtlar için ayrı ayrı analiz yapılarak TBDY-2018'e göre *Göçmenin Önlenmesi* performans düzeyini sağlamak üzere VSS özellikleri araştırılmıştır. Buna göre güçlendirme öncesi için oluşturulan modele farklı kuvvet ve sönüm kapasitelerine sahip VSS'ler kullanılmış ve uzak fay grubuna ait model 4KB-SU, yakın fay grubuna ait model 4KB-SY olarak adlandırılmıştır (Şekil 3). Tüm modellerde kolon ve kirişlerin doğrusal olmayan davranışları yığılı plastisite yaklaşımı ile temsil edilmiş ve ASCE/SEI 41-17'ye göre belirlenen moment-plastik dönme bağıntıları kullanılmıştır (ASCE, 2017). Kolonlarda iki eksenli bileşik eğilme etkileri göz önüne alınmıştır. Dolgu duvarlar, yalnızca basınç kuvveti taşıyan iki ucu mafsallı eşdeğer diyagonal çubuklarla temsil edilmiş ve bunlara ait kuvvet–deformasyon ilişkileri TBDY-2018 (AFAD, 2018) esas alınarak tanımlanmıştır. Düğüm noktaları ve döşemeler için doğrusal davranış kabul edilmiş, döşemelerin düzlem içi rijitliği diyafram davranışı ile modele yansıtılmıştır. Analizlerde PERFORM-3D (CSI, 2023) programı kullanılmıştır. Doğrusal olmayan modellemeye ait detaylı bilgi Aşıcı (2025)'de bulunmaktadır.

Şekil 3. VSS'lerin planda ve düşey kesitteki yerleşimi ve kuvvet-hız ilişkisi



VSS'lerin hıza önemli ölçüde duyarlı olmaları nedeniyle çalışmada uzak ve yakın fay karakteristiğine sahip iki ayrı grup oluşturulmuştur. Bu kayıtlara ait temel özellikler Tablo 1,2'de verilmiştir (PEER, 2024). Çalışmada, en büyük (maksimum) deprem yer hareketi düzeyi (DD-1) için *Göçmenin Önlenmesi* performans düzeyinin sağlanabilirliği araştırıldığı için seçilen kayıtlar, tasarım deprem düzeyinin (DD-2) spektral olarak 1.5 katı olarak kabul edilen hedef spektruma göre genlik ölçekleme yaklaşımı ile ölçeklenmiştir (Şekil 4) (ASCE, 2023).

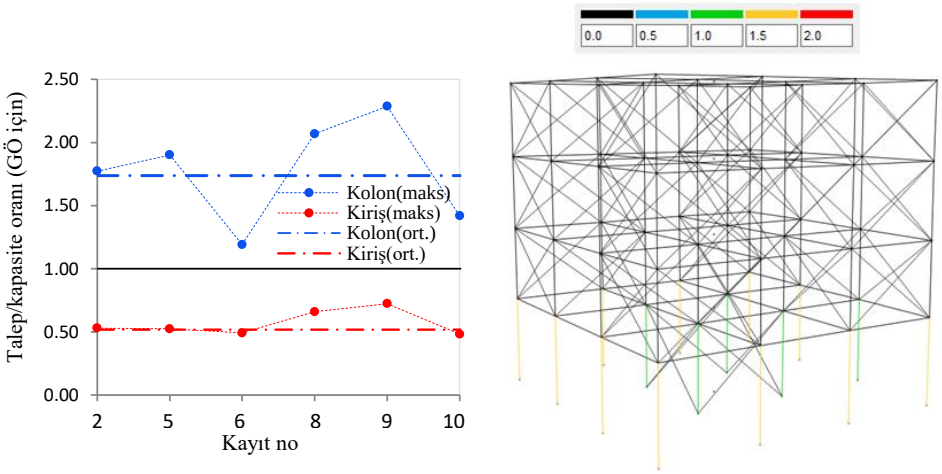
Şekil 4. Uzak (sol) ve yakın (sağ) fay deprem grupları için ölçeklenmiş ivme spektrumları ve tasarım spektrumu

Analiz Sonuçları

Uzak ve yakın fay gruplarındaki toplam 22 kayıt için iki doğrultulu olarak gerçekleştirilen doğrusal olmayan dinamik analizler sonucunda güçlendirme öncesi ve sonrası modellerde göçme oluşan ve



oluşmayan durumlar Tablo 3'de gösterilmiştir. Güçlendirme öncesi yumuşak düzensizliği bulunan modelde (4KB) uzak fay grubundaki 5 deprem kaydı için göçme oluşurken, yakın fay gubunda bu sayı 9'a çıkmıştır. Uzak fay grubu için VSS ile yapılan güçlendirme sonucunda tüm göçme durumları engellenmiş ve TBDY-2018'e göre *Göçmenin Önlenmesi* performans düzeyi sağlanmıştır. Yakın fay grubu için ise düzensizliğin bulunduğu kattaki deformasyonlar VSS'ler ile kontrol altına alınmasına rağmen üst katlardaki deformasyonlar nedeniyle 5 adet deprem kaydında göçme durumu oluşmuştur.

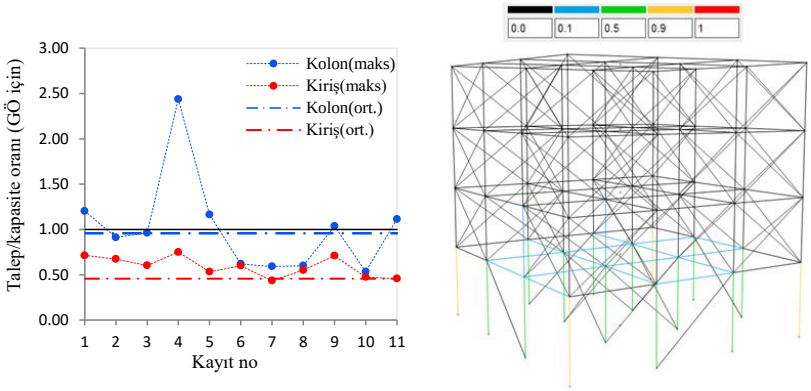
Talep/kapasite oranları

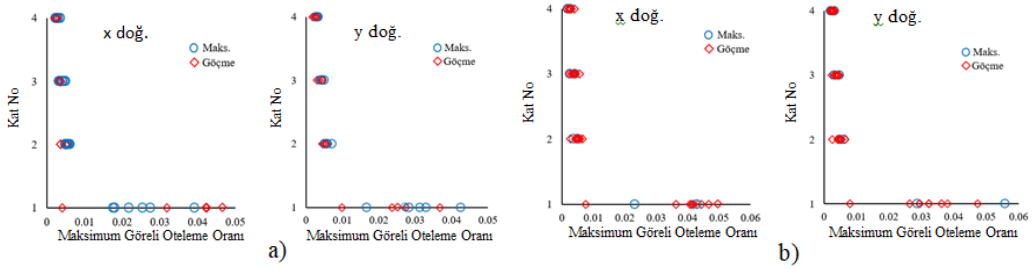


Güçlendirme öncesi modelde (4KB), göçmeler genellikle yumuşak katta meydana gelen mekanizma ile veya kolon dönme kapasitesinin aşılması nedeniyle oluşmuştur. Göçme durumu oluşmayan 6 deprem kaydının her biri için tüm elemanlardaki en elverişsiz (maks.) plastik dönme talepleri, *Göçmenin Önlenmesi* performans düzeyine ait sınırlara oranlanarak için talep/kapasite oranları belirlenmiş ve Şekil 5'te gösterilmiştir. Ayrıca, talep/kapasite oranlarının sistem elemanlarındaki karşılıkları ortalama değerler üzerinden renklendirilmiş ölçek ile Şekil 5'te verilmiştir. Tüm kolonlarda ve kayıtlarda *Göçmenin Önlenmesi* düzeyine karşılık gelen plastik dönme talepleri önemli oranda aşılmış, 6 kayıt için en elverişsiz değerlere ait ortalama talep/kapasite oranı 1.75 elde edilmiştir. Kirişlerde ise tüm kayıtlarda 1.0'in altında oranlar elde edilmiş, ortalama oran 0.5 elde edilmiştir.

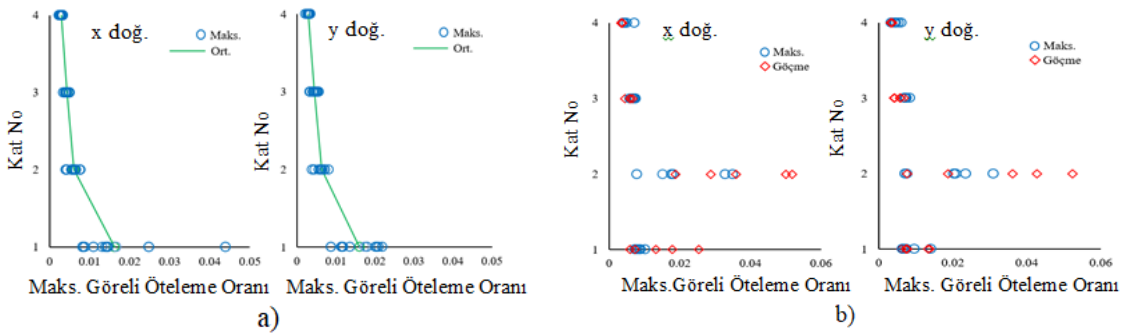
Şekil 5. 4KB modelinde 6 uzak fay grubu deprem kaydı için talep/kapasite oranları

Uzak fay deprem grubu için güçlendirilen modele (4KB-SU) için elde edilen talep/kapasite oranları Şekil 6'da verilmiştir. VSS kullanımı ile düzensizliğin bulunduğu kattaki plastik dönme taleplerinin

kapasiteye oranları ortalamada kolonlar için 1.0'e çok yakın elde edilirken, kirişler için yaklaşık 0.5 elde edilmiştir. 4 adet kayıtta kolonlardaki maksimum oran 1.0'i aşmıştır. Kirişlerde ise maksimum oran 0.70 elde edilmiştir. En elverişsiz talep/kapasite oranları köşe kolonlarda elde edilmiş, diğer kolonlarda oranlar genellikle 0.50-0.90 arasında kalmıştır. 2. Katta sadece 2 adet kolonda 0.10'luk oran aşılmış, diğer elemanlar ya plastikleşmemiş ya da talep/kapasite oranları 0.10'un altında kalmıştır.



Şekil 6. Uzak fay grubu için güçlendirilmiş modelde (4KB-SU) talep/kapasite oranları

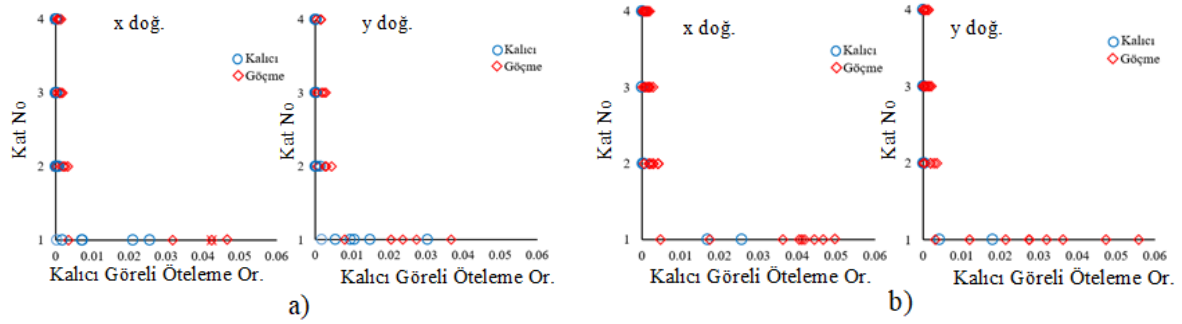


Maksimum göreli kat ötelemesi oranları

Güçlendirme öncesi model (4KB) için uzak ve yakın fay grubu kayıtlarından elde edilen maksimum göreli kat ötelemesi oranları x ve y doğrultuları için Şekil 7'de verilmiştir. Grafiklerde göçme durumu kayıtlar için analiz sonlanmadan önce elde edilen maksimum göreli kat ötelemesi oranları kırmızı ile gösterilmiştir. Şekil 7'den görüldüğü gibi, göçme oluşmayan depremlerde dahi düzensizliğin bulunduğu kattaki göreli kat ötelemesi oranları uzak fay için % 2-4 arasında, yakın fay için %2-6 arasında elde edilmiştir. Göçme oluşan durumlarda da göçme öncesi benzer öteleme oranları gözlenmiş ve sonrasında mekanizma ve/veya kapasite sonlanması nedeniyle analiz tamamlanamıştır.

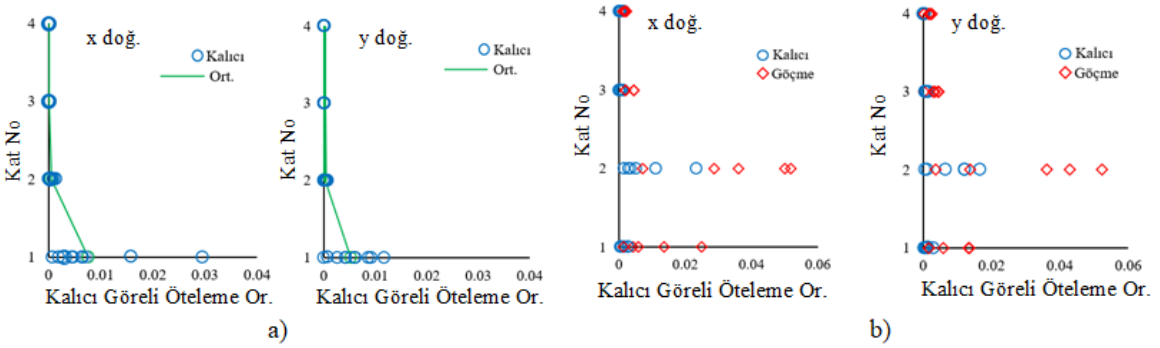
Uzak fay ve yakın fay grubu depremler için güçlendirilen 4KB-SU ve 4KB-SY modellerinde elde edilen maksimum göreli öteleme oranları Şekil 8'de verilmiştir. 4KB-SU modelinde sadece 2 kayıt için maksimum oranlar %2.0'yi aşmış, buna karşılık düzensizliğin bulunduğu kata ait oran % 2.0'nin altında kalmıştır (Şekil 8a).

Şekil 7. Güçlendirme öncesi modelde(4KB) maks. göreli kat öteleme oranları a) Uzak fay grubu, b) Yakın fay grubu



Şekil 8. Güçlendirilen modellerde maks. göreli kat öteleme oranları a) Uzak fay grubu (4KB-SU), b) Yakın fay grubu (4KB-SY)

Yakın fay grubu için güçlendirilen 4KB-SY modelinde de kullanılan VSS'ler ile düzensizliğin bulunduğu kattaki ötelemeler kontrol altına alınmış, ancak bir üst kattaki ötelemelerin önemli ölçüde artması nedeniyle *Göçmenin Önlenmesi* performans düzeyi sağlanamamış veya göçme durumu oluşmuştur. Buna göre 4KB-SY modelinde maksimum deprem düzeyi için VSS'ler ile göçmenin tamamen önlenebilirliği sağlanamamıştır.



Kalıcı göreli kat öteleme oranları

Güçlendirme öncesi model (4KB) için uzak ve yakın fay grubu kayıtlarından elde edilen kalıcı göreli kat ötelemesi oranları x ve y doğrultuları için Şekil 9'da verilmiştir. Yumuşak kat düzensizliğinin bulunduğu katta kalıcı ötelemeler göçme oluşmayan durumlarda %3.0'lere, göçme gözlenen durumlarda ise göçme öncesinde %6.0'lara ulaşmıştır.

Uzak fay ve yakın fay grubu depremler için güçlendirilen 4KB-SU ve 4KB-SY modellerinde elde edilen kalıcı göreli öteleme oranları Şekil 10'da verilmiştir. *Göçmenin Önlenmesi* performans düzeyinin sağlandığı uzak fay deprem grubu için ortalama kalıcı öteleme oranları her iki doğrultu için de %1.0'in altında kalmıştır. Sadece 2 kayıt için %1.0'lik kalıcı göreli öteleme oranı aşılmıştır. En büyük deprem yer hareketi düzeyi (DD-1) için elde edilen bu sonuçların, eleman hasar düzeylerini temsil eden *Göçmenin Önlenmesi* performans düzeyi ile uyumlu olduğu söylenebilmektedir. Yakın fay grubu için güçlendirilen modelde VSS'ler ile düzensizliğin bulunduğu kattaki kalıcı göreli öteleme oranları büyük ölçüde kontrol altına alınmakla birlikte 2. katta oluşan kalıcı öteleme oranları bazı kayıtlarda göçmeye yol açmış bazı kayıtlarda ise öngörülen performansın çok üzerinde plastik dönmelere sebep olmuştur.

Şekil 9. Güçlendirme öncesi modelde(4KB) Kalıcı göreli kat öteleme oranları a) Uzak fay grubu, b) Yakın fay grubu

Şekil 10. Güçlendirilen modellerde kalıcı göreli kat öteleme oranları a) Uzak fay grubu (4KB-SU), b) Yakın fay grubu (4KB-SY)

SONUÇLAR VE ÖNERİLER

Bu çalışmada, yumuşak kat düzensizliği bulunan dört katlı betonarme bir bina modelinin en büyük deprem yer hareketi (DD-1) düzeyindeki uzak ve yakın fay karakteristiğine sahip deprem kayıtları altındaki performansı ve yalnızca yumuşak katta uygulanan viskoz sıvılı sönümleyicilerin (VSS) göçmeyi önlemedeki etkinliği incelenmiştir. Elde edilen sonuçlar genel olarak aşağıda verilmiştir.

Güçlendirme öncesi 4KB modelinde yumuşak kat düzensizliği, özellikle yakın fay kayıtlarında yüksek maksimum ve kalıcı göreli kat ötelemelerine ve yaygın göçme durumlarına neden olmuştur. Uzak fay grubunda 11 kaydın 5'inde, yakın fay grubunda ise 9'unda göçme meydana gelmiştir.

VSS uygulaması, her iki deprem grubunda da yumuşak kattaki deformasyon taleplerini belirgin biçimde azaltmıştır. Uzak fay grubunu temsil eden 4KB-SU modelinde tüm göçme durumları önlenmiş ve Göçmenin Önlenmesi performans düzeyi sağlanmıştır. Buna karşılık yakın fay grubunda 4KB-SY modeliyle yumuşak kattaki talepler kontrol altına alınmasına rağmen bazı kayıtlarda göçme devam etmiş ve hedeflenen performans düzeyi sağlanamamıştır.

Sonuç olarak, incelenen bina modeli ve deprem kayıtları kapsamında VSS'ler, özellikle uzak fay karakteristiğine sahip yer hareketleri altında yumuşak kat göçmesinin önlenmesi açısından etkili bir güçlendirme seçeneği olmuştur. Ancak yakın fay hareketlerinde elde edilen sonuçlar, sönümleyici kapasitesinin artırılmasının ve sadece düzensizlik bulunan katta kullanımın yeterli olmayabileceğini göstermiştir.

Gelecek çalışmalarda değerlendirmelerin farklı kat sayılarına, bina geometrilerine, taşıyıcı sistem özelliklerine ve yumuşak kat oluşum biçimlerine sahip bina modelleri için genişletilmesi önerilmektedir. Ayrıca VSS'lerin global bina davranışına etkisinin yanı sıra, sönümleyicilerin bağlandığı kolon, kiriş ve bağlantı bölgelerinde oluşturduğu lokal iç kuvvet ve deformasyon taleplerinin ayrıntılı olarak incelenmesi gerekmektedir. Özellikle yakın fay hareketlerinde deformasyon taleplerinin üst katlara yeniden dağılımı, farklı VSS yerleşimleri, sönümleyici kapasiteleri ve güçlendirme stratejileri açısından araştırılmalıdır.

TALAŞLI İMALATTA DİJİTAL ÜRÜN PASAPORTU VE KARBON İZLENEBİLİRLİĞİ: SÜRDÜRÜLEBİLİR ÜRETİM İÇİN GÜNCEL BİR DEĞERLENDİRME

DIGITAL PRODUCT PASSPORTS AND CARBON TRACEABILITY IN MACHINING: A CONTEMPORARY REVIEW FOR SUSTAINABLE MANUFACTURING

Asst. Prof. Dr. Hakan YURTKURAN
Yozgat Bozok University, Akdağmadeni Vocational School, Department of Machinery and Metal Technologies, Yozgat, Türkiye
ORCID NO: 0000-0003-2375-7316

ÖZET
Sürdürülebilir üretim ve döngüsel ekonomi hedefleri, ürünlerin malzeme içeriği ile üretim ve yaşam döngüsü boyunca meydana gelen çevresel etkilerin güvenilir biçimde izlenmesini gerekli hâle getirmiştir. Dijital Ürün Pasaportu (DÜP), ürün kimliği, malzeme bileşimi, üretim geçmişi, çevresel performans, bakım, yeniden kullanım ve geri dönüşüm bilgilerinin bütünleşik bir dijital yapı içinde paylaşılmasını sağlayan güncel bir yaklaşımdır. Bu çalışmada DÜP yaklaşımının talaşlı imalat süreçlerindeki karbon izlenebilirliği açısından uygulanabilirliği değerlendirilmiş ve bu süreçlere özgü kavramsal bir veri çerçevesi geliştirilmiştir. Konu odaklı literatür incelemesi kapsamında dijital ürün pasaportları, sürdürülebilir talaşlı imalat, enerji tüketimi, kesici takımların ve kesme sıvılarının yaşam döngüsü ile işlem kaynaklı karbon emisyonlarını ele alan 13 çalışma incelenmiştir. Bulgular, talaşlı imalatın karbon ayak izinin yalnızca tezgâh elektriğinden oluşmadığını göstermektedir. Hammadde, kesici takım, kesme sıvısı, işlem süresi, boşta çalışma, talaş oluşumu ve geri kazanım uygulamalarının da hesaba katılması gerektiğini göstermektedir. Bu doğrultuda DÜP için ürün ve malzeme bilgileri, işlem bilgileri, enerji tüketimi, takım ve kesme sıvısı kullanımı, atık ve geri kazanım bilgileri ile karbon göstergelerinden oluşan altı bileşenli bir çerçeve önerilmiştir. Çerçeve, karbon yoğun işlemlerin belirlenmesi ve alternatif üretim stratejilerinin karşılaştırılması için uygulanabilir bir başlangıç sunmaktadır. Veri standardizasyonu, sistemler arası birlikte çalışabilirlik, ticari bilgilerin korunması ve karbon hesabı sınırlarının belirlenmesi temel uygulama güçlükleridir.
Anahtar kelimeler: Dijital ürün pasaportu, talaşlı imalat, karbon izlenebilirliği, sürdürülebilir üretim, döngüsel ekonomi.

ABSTRACT
Sustainable manufacturing and circular economy objectives require reliable traceability of material content and environmental impacts throughout manufacturing and product life cycles. The Digital Product Passport (DPP) is an emerging approach that enables product identification, material composition, manufacturing history, environmental performance, maintenance, reuse and recycling information to be shared within an integrated digital structure. This study evaluates the applicability of DPPs to carbon traceability in machining and develops a conceptual data framework tailored to machining processes. A topic-focused literature review examined 13 studies addressing digital product passports, sustainable machining, energy consumption, the life cycles of cutting tools and cutting fluids, and process-related carbon emissions. The findings show that the carbon footprint of machining is not limited to machine-tool electricity. Raw material, cutting tools, cutting fluids, processing time, idle operation, chip generation and recovery practices should also be considered. Accordingly, a six-component DPP framework is proposed, comprising product and material information, process information, energy consumption, tool and cutting-fluid use, waste and recovery information, and carbon indicators. The framework provides a practical starting point for identifying carbon-intensive operations and comparing alternative manufacturing strategies. Data standardisation, interoperability, protection of commercially sensitive information and the definition of carbon-accounting boundaries remain the main implementation challenges.
Keywords: Digital product passport, machining, carbon traceability, sustainable manufacturing, circular economy.

GİRİŞ

İmalat sanayisi ekonomik değer üretirken enerji ve malzeme tüketimi, sera gazı emisyonları ve atık oluşumu bakımından önemli çevresel etkilere yol açmaktadır. Karbon azaltma hedefleri, üretim işletmelerini yalnızca toplam enerji tüketimini izlemeye değil, bu tüketimin hangi ürün, operasyon ve süreç koşullarından kaynaklandığını belirlemeye yöneltmektedir. Talaşlı imalat bu açıdan dikkat çekici bir alandır. İş parçasından malzeme uzaklaştırılması sırasında tezgâh elektriği, hammadde, kesici takım, kesme sıvısı ve yardımcı sistemler birlikte kullanılmaktadır. İşlem sonunda talaş, kullanılmış akışkan ve aşınmış takım gibi farklı atık akışları oluşmaktadır. Bu nedenle bir parçanın üretim kaynaklı karbon ayak izi tek bir enerji ölçümüyle açıklanamaz (Li vd., 2015; Wang vd., 2023; Wu vd., 2025).

Talaşlı imalatta çevresel performansın iyileştirilmesine yönelik çalışmalar ise enerji modelleme, kesme parametrelerinin optimizasyonu, çevre dostu soğutma ve yağlama stratejileri ile takım ve süreç performansının geliştirilmesi gibi farklı alanlarda yoğunlaşmaktadır (Rajmohan vd., 2020; Wang vd., 2023). Kesme hızı, ilerleme ve kesme derinliği paremetreleri işlem süresini, enerji ve malzeme tüketimini, takım ömrünü ve üretim maliyetini birlikte etkilediğinden karbon emisyonu, maliyet ve işlem süresi hedefleri arasında bir denge kurulması gerekmektedir (Zhou vd., 2019). Benzer şekilde operasyon sırası ve çizelgeleme kararları da boşta çalışma sürelerini ve toplam karbon ayak izini değiştirebilmektedir (Lin vd., 2015). Bununla birlikte bu çalışmaların ürettiği verilerin ürünün kimliğiyle ilişkilendirilmesi ve yaşam döngüsü boyunca erişilebilir tutulması hâlen önemli bir araştırma ve uygulama alanıdır.

Dijital Ürün Pasaportu, ürün tanımlama, ürün ve malzeme özellikleri, kullanım ve bakım, tedarik zinciri ve tersine lojistik, çevresel performans ve mevzuata uygunluk bilgilerinin dijital bir yapı içerisinde saklanmasını ve ilgili tedarik zinciri aktörleri arasında paylaşılmasını amaçlamaktadır. DÜP kapsamında ihtiyaç duyulan veriler, desteklenen karar ve kullanım durumunun yanı sıra veriyi kullanan tedarik zinciri aktörünün rolüne göre farklılaşmaktadır (Jensen vd., 2023). Bu nedenle Dijital Ürün Pasaportu, yalnızca ürüne iliştirilen bir QR kod veya benzeri fiziksel veri taşıyıcısı olarak değerlendirilmemelidir. QR kod, kullanıcıyı ürünün dijital kaydına yönlendiren bir erişim aracı niteliğindedir; DÜP'ün kendisi ise standartlaştırılmış veri tanımları ve modelleri, benzersiz ürün kimliği, farklı paydaşlara göre düzenlenen erişim yetkileri, veri güvenliği ve doğrulama mekanizmaları, sistemler arası birlikte çalışabilirlik ve ürünün tüm yaşam döngüsü boyunca oluşturulan veri akışları üzerine kurulu kapsamlı bir bilgi mimarisidir (Psarommatis ve May, 2024; Wicaksono vd., 2025). Avrupa Birliği'nin 2024/1781 sayılı Sürdürülebilir Ürünler için Eko-Tasarım Tüzüğü de ürün bilgilerinin dijital olarak erişilebilir kılınmasına yönelik hukuki çerçeveyi güçlendirmiştir (European Union, 2024).

Bu çalışmanın amacı, DÜP yaklaşımını talaşlı imalatın karbon kaynaklarıyla ilişkilendirmek ve işlem düzeyinde kullanılabilecek kavramsal bir veri çerçevesi önermektir. Çalışmanın araştırma sorusu "Bir parçanın talaşlı imalat sürecinde oluşan karbon bilgisi, ürün yaşam döngüsü boyunca hangi veri bileşenleriyle izlenebilir?" biçiminde tanımlanmıştır. Çalışmanın özgün katkısı, DÜP literatüründeki ürün ve yaşam döngüsü veri gereksinimleri ile talaşlı imalattaki ölçülebilir çevresel girdileri altı bileşenli ortak bir yapıda eşleştirmesidir.

YÖNTEM

Çalışmada konu odaklı literatür incelemesi yöntemi kullanılmıştır. İnceleme, sistematik derleme veya meta-analiz iddiası taşımamaktadır. Birbirini tamamlayan üç literatür akışını kavramsal olarak sentezlemektedir. Birinci akış DÜP'ün tanımı, veri kümeleri, aktörleri, standardizasyonu ve benimsenme güçlüklerini, ikinci akış sürdürülebilir talaşlı imalatın ekipman, işlem ve strateji boyutlarını, üçüncü akış ise enerji, malzeme, kesici takım, kesme sıvısı ve atık kaynaklı karbon modelleme yaklaşımlarını kapsamaktadır.

İnceleme kümesi, 2013-2025 döneminde yayımlanmış 13 hakemli çalışmadan oluşturulmuştur. Çalışmalar konuya doğrudan katkı sunması, talaşlı imalatın çevresel girdilerinden en az birini ele alması veya DÜP için ürün yaşam döngüsü verilerini tanımlaması ölçütleriyle değerlendirilmiştir. Ayrıca DÜP'ün düzenleyici bağlamını göstermek amacıyla Avrupa Birliği'nin 2024/1781 sayılı Tüzüğü incelenmiştir. Her çalışma amaç, kapsam, veri türü ve önerilen çerçeveye katkısı bakımından kodlanmıştır. Kodlama sonucunda yinelenen veri gereksinimleri altı ana bileşen altında birleştirilmiştir.

Tablo 1. İncelenen literatür akışlarının çalışma çerçevesine katkısı

Literatür akışı	İncelenen konu	Çerçeveye aktarılan veri	Temel kaynaklar
Dijital ürün pasaportu	Yaşam döngüsü kararları, veri kümeleri, erişim ve benimsenme	Ürün kimliği, malzeme bilgisi, çevresel göstergeler, kullanım ve bakım kayıtları, yaşam sonu bilgileri, veri güvenliği ve birlikte çalışabilirlik	Jensen vd. (2023); Psarommatis ve May (2024); Wicaksono vd. (2025)
Sürdürülebilir talaşlı imalat	Tezgâh, işleme süreci, kesici takım, kesme sıvısı ve sürdürülebilir işleme stratejileri	Tezgâh, operasyon, kesme parametreleri, takım kullanımı, soğutma/yağlama koşulları ve süreç optimizasyonu	Wang vd. (2023); Rajmohan vd. (2020)
Karbon modelleme ve optimizasyon	Enerji tüketimi, hammadde, kesici takım, kesme sıvısı, talaş ve süreç optimizasyonu	Tezgâhın boşta ve yükte enerji tüketimi, malzeme ve yardımcı girdi tüketimi, talaş oluşumu, CO_2e ve karbon–süre–maliyet dengesi	Li vd. (2015); Zhou vd. (2019); Wu vd. (2025)
Yaşam döngüsü değerlendirmesi	Kesici takım ve kesme sıvısının üretim, kullanım, bakım/yenileme ve yaşam sonu aşamaları	Fonksiyonel birim, sistem sınırı, takım ömrü, yeniden bileme ve kaplama, kesme sıvısı türü ve miktarı, enerji tüketimi, bertaraf ve geri kazanım	Li vd. (2017); Khanna vd. (2021); Shah vd. (2021)

BULGULAR VE TARTIŞMA

Dijital Ürün Pasaportunun Veri Yapısı

DÜP literatürü, ürün verisinin tek bir paydaşın ihtiyacına göre tanımlanamayacağını göstermektedir. Tedarikçi, üretici, bakım hizmeti sağlayıcısı, müşteri ve geri dönüşüm işletmesi aynı ürüne farklı karar noktalarından yaklaşmaktadır. Üretici malzeme ve süreç bilgisini kullanırken bakım sağlayıcısı kullanım koşulları ile bileşen geçmişine, geri dönüşüm işletmesi ise malzeme ayrıştırma ve tehlikeli içerik bilgisine ihtiyaç duymaktadır. Jensen vd. (2023), bu nedenle DÜP veri gereksinimlerinin yaşam döngüsü kararı ve kullanıcı rolüyle birlikte belirlenmesi gerektiğini göstermiştir. Talaşlı imalat bağlamında bu yaklaşım, tezgâh ve proses verilerinin doğrudan ürüne aktarılmasından önce verinin hangi sürdürülebilirlik kararını desteklediğinin tanımlanmasını gerektirir.

DÜP'ün etkili olabilmesi için veri doğruluğu, güncellik, birlikte çalışabilirlik ve erişim kontrolü birlikte sağlanmalıdır. Üretim parametrelerinin tamamının herkese açık biçimde paylaşılması ticari sır ve fikrî mülkiyet açısından uygun değildir. Buna karşılık karbon yoğunluğu, geri dönüştürülmüş içerik veya yaşam sonu talimatları gibi doğrulanabilir göstergelerin tedarik zinciri boyunca paylaşılması gerekir. Psarommatis ve May (2024), Dijital Ürün Pasaportu'nu ürünün üretim, kullanım ve döngüsellik aşamalarında oluşan verileri bütünleştirerek izlenebilirliği, yaşam döngüsü yönetimini ve sürdürülebilir üretimi destekleyen bir yapı olarak ele almaktadır. Wicaksono vd. (2025) ise DÜP'ün uygulanabilirliğini ve teknik altyapı, veri standardizasyonu, sistemler arası birlikte çalışabilirlik, veri yönetişimi, paydaş katılımı ve benimsenme koşulları çerçevesinde değerlendirmektedir. Bu doğrultuda talaşlı imalata yönelik bir DÜP yapısı, operasyon ve kaynak kullanımına ilişkin ayrıntılı süreç verilerini yaşam döngüsü boyunca korumalıdır. Diğer taraftan paydaşlara rolleri ve kullanım amaçlarıyla sınırlandırılmış, güvenli erişim yetkileri sunmalıdır (Psarommatis ve May, 2024; Wicaksono vd., 2025).

Talaşlı İmalatta Karbon Kaynakları

CNC tabanlı talaşlı imalat sistemlerinde karbon emisyonu beş ana kaynak grubunda ele alınabilir: elektrik, hammadde, kesici takım, kesme sıvısı ile talaş ve diğer atıklar. Elektrik kaynaklı emisyon, aktif

kesme, eksen hareketleri, takım değiştirme, soğutma, basınçlı hava ve boşta çalışma gibi farklı durumlarda tüketilen enerjinin ilgili elektrik emisyon faktörüyle çarpılması yoluyla hesaplanabilir. Ancak toplam etkinin yalnızca tezgâh elektriğine indirgenmesi, malzemenin gömülü karbonunu ve sarf girdilerini görünmez hâle getirir. Li vd. (2015), CNC tabanlı işleme sistemlerinde elektrik tüketimi, hammadde, kesme sıvısı, kesici takım ve talaş yönetiminden kaynaklanan emisyonları birlikte değerlendiren analitik bir nicel yöntem önermiştir. Wu vd. (2025) ise tornalama, frezeleme, delme, taşlama ve dişli azdırma başta olmak üzere farklı imalat süreçleri için geliştirilen karbon emisyonu modellerini sistematik olarak incelemiştir. Kesme parametreleri, takım ve iş parçası özellikleri, enerji tüketimi, kesme sıvısı kullanımı ve atık yönetiminin emisyonlar üzerindeki etkilerini bütüncül biçimde değerlendirmiştir. Hammadde kaynaklı etki, başlangıç kütlesi ile nihai parça kütlesi arasındaki farkın ve malzemeye özgü emisyon faktörünün bilinmesini gerektirir. Uzaklaştırılan talaşın kirlenme düzeyi ve geri kazanım senaryosu bu hesabı değiştirebilir. Ayrı toplanan ve geri dönüştürülen metal talaşı ile kesme sıvısıyla yoğun biçimde kirlenmiş talaş aynı çevresel sonuca sahip değildir. Bu nedenle DÜP kaydı yalnızca talaş miktarını değil, malzeme türünü, kirlenme durumunu, taşıma ve geri kazanım senaryosunu da içermelidir.

Kesme hızı, ilerleme ve kesme derinliği gibi işlem parametreleri enerji ve malzeme tüketimini, işlem süresini, takım ömrünü ve üretim maliyetini birlikte etkileyebilmektedir. Bu nedenle düşük karbonlu talaşlı imalatta tek bir performans göstergesinin iyileştirilmesi yerine çevresel ve ekonomik hedeflerin birlikte değerlendirilmesi gerekmektedir. Zhou vd. (2019), kesme parametrelerini karbon emisyonu, kesme süresi ve kesme maliyeti bakımından eş zamanlı olarak ele alan çok amaçlı bir optimizasyon yaklaşımı geliştirmiştir. Bununla birlikte çevresel performans yalnızca kesme bölgesindeki parametrelere bağlı değildir. işlerin işlenme sırası, hazırlık süreleri, tezgâhların boşta bekleme süreleri ve çizelgeleme kararları da toplam üretim süresini ve karbon ayak izini etkilemektedir. Lin vd. (2015), tornalama süreçleri için işlem parametresi optimizasyonu ile akış tipi üretim çizelgelemesini bütünleştirerek toplam tamamlanma süresi ve karbon ayak izini birlikte en aza indirmeyi amaçlamıştır.

Kesici Takım ve Kesme Sıvısının Yaşam Döngüsü

Kesme sıvıları, takım–iş parçası ara yüzündeki sürtünme ve sıcaklığın kontrol edilmesine katkı sağlayarak takım ömrünü ve işlenmiş yüzey kalitesini iyileştirebilir. Bununla birlikte kesme sıvısının üretimi ve hazırlanması, sisteme iletilmesi için tüketilen enerji, kullanım sırasındaki bakım gereksinimi ve yaşam sonundaki arıtma, bertaraf veya geri kazanım işlemleri ek çevresel ve sağlık etkileri oluşturabilmektedir. Bu nedenle MQL, kriyojenik soğutma, kuru kesme ve geleneksel taşırma soğutma seçenekleri yalnızca kullanılan sıvı miktarına göre değerlendirilmemelidir. Aynı zamanda enerji tüketimi, takım ve yüzey performansı, insan sağlığı ve yaşam döngüsü etkileri birlikte dikkate alınarak karşılaştırılmalıdır. Khanna vd. (2021), taşırma, MQL ve LCO_2 koşullarını işleme performansı, çevresel etki ve insan sağlığı bakımından karşılaştırırken, Shah vd. (2021), taşırma, LCO_2 ve LN_2 koşullarını enerji tüketimi, yüzey kalitesi ve yaşam döngüsü etkileri üzerinden değerlendirmiştir. Ross vd. (2023) ise kuru, MQL, kriyojenik CO_2 ve nano-MQL koşullarında enerji tüketimi ile karbon emisyonlarının önemli ölçüde değişebildiğini göstermiştir. Bu bulgulardan hareketle DÜP içerisinde kesme sıvısının türü ve bileşimi, konsantrasyonu, kullanılan ve yenilenen miktarı, kullanım/değişim süresi, enerji gereksinimi ve yaşam sonu yönetim yöntemi temel kayıt alanları olarak tanımlanabilir.

Önerilen Altı Bileşenli DÜP Çerçevesi

Literatür sentezi sonucunda talaşlı imalat için altı veri bileşeninden oluşan kavramsal DÜP çerçevesi geliştirilmiştir. Çerçeve, çevresel sonucu tek başına saklamak yerine sonucu üreten süreç bağlamını da ürün kaydıyla ilişkilendirmektedir. Böylece farklı tezgâh, parametre ve üretim senaryoları karşılaştırılabilir. Hesaplamanın tekrar edilebilirliği ve doğrulanabilirliği artırılabilir. Önerilen bileşenler ve örnek veri alanları Tablo 2'de sunulmuştur.

Tablo 2. Talaşlı imalat için önerilen Dijital Ürün Pasaportu veri çerçevesi

No	Veri bileşeni	Örnek alanlar	Birim / biçim	İzlenebilirlik amacı
1	Ürün ve malzeme	Parça kimliği, revizyon, alaşım, tedarikçi, başlangıç ve son kütle	Metin, kg	Ürünü ve malzeme kaybını tanımlama
2	İşlem bilgisi	Operasyon, tezgâh, kesme hızı, ilerleme, kesme derinliği, işlem ve bekleme süresi	m/min, mm/dev, mm, dk	Karbon hesabının süreç bağlamını koruma
3	Enerji	Aktif kesme, boşta çalışma ve yardımcı ekipman tüketimi; elektrik emisyon faktörü	kWh, kg CO2e/kWh	Elektrik kaynaklı emisyonu hesaplama
4	Takım ve kesme sıvısı	Takım türü ve ömrü, yenileme; sıvı türü, konsantrasyon, tüketim ve devridaim	dk, adet, L, %	Sarf girdilerini yaşam döngüsüyle ilişkilendirme
5	Atık ve geri kazanım	Talaş miktarı ve kirlenmesi, kullanılmış sıvı, aşınmış takım, taşıma ve geri kazanım senaryosu	kg, L, %, metin	Atık yönetimi ve döngüselliği izleme
6	Karbon göstergeleri	Toplam emisyon, birim emisyon, fonksiyonel birim, sistem sınırı, veri kaynağı ve hesap tarihi	kg CO2e; kg CO2e/parça	Karşılaştırılabilir ve doğrulanabilir sonuç üretme

Birinci bileşen, parçanın ve kullanılan hammaddenin benzersiz biçimde tanımlanmasını sağlar. İkinci ve üçüncü bileşenler, işlemin hangi tezgâhta ve hangi koşullarda gerçekleştirildiğini enerji tüketimiyle birlikte kaydeder. Dördüncü bileşen, geleneksel enerji odaklı hesaplarda çoğu zaman ihmal edilen takım ve akışkan girdilerini görünür kılar. Beşinci bileşen üretim sonrası akışları döngüsel ekonomi kararlarıyla ilişkilendirir. Altıncı bileşen ise tüm girdileri tanımlı bir sistem sınırı ve fonksiyonel birim altında karbon göstergesine dönüştürür. Bu yapı, toplam CO2e değerinin yanı sıra değerin hesaplanmasında kullanılan sınır, emisyon faktörü ve veri tarihini de saklayarak karşılaştırmanın güvenilirliğini artırır.

Beklenen Yararlar ve Uygulama Güçlükleri

Önerilen çerçeve, işletme düzeyinde karbon yoğun operasyonların belirlenmesine ve alternatif üretim planlarının karşılaştırılmasına yardımcı olabilir. Aynı parçanın farklı tezgâhlar, kesme parametreleri veya soğutma stratejileri altında üretilmesi durumunda parça başına karbon göstergesi ortak bir fonksiyonel birim üzerinden karşılaştırılabilir. Malzeme kaybı ve talaş geri kazanımı hakkındaki kayıtlar, geri dönüşüm ve yeniden kullanım kararlarını destekleyebilir. Ürün bazlı izlenebilirlik, kurumsal karbon envanterinin süreç düzeyinde açıklanmasını ve tedarik zincirinde doğrulanabilir çevresel bilgi paylaşımını da kolaylaştırabilir.

Bununla birlikte DÜP'ün ölçeklenmesi için dört temel sorun çözülmelidir. İlk olarak farklı tezgâh, üretim yürütme sistemi ve kurumsal kaynak planlama yazılımlarından gelen veriler ortak bir sözlükte tanımlanmalıdır. İkinci olarak veri kalitesi ve ölçüm sıklığı güvence altına alınmalıdır. Nominal tezgâh gücü ile gerçek zamanlı enerji ölçümü aynı doğruluk düzeyinde değildir. Üçüncü olarak süreç reçeteleri ve maliyet bilgileri gibi ticari açıdan hassas veriler için rol temelli erişim uygulanmalıdır. Son olarak sistem sınırı, elektrik emisyon faktörü, geri dönüşüm kredisi ve fonksiyonel birim seçimi açık biçimde

belirtilmelidir. Aksi hâlde aynı ürün için hesaplanan iki karbon göstergesi görünürde benzer olsa bile gerçekte karşılaştırılabilir olmayabilir.

Bu çalışma kavramsal bir çerçeve sunduğu için gerçek üretim ortamında doğrulama yapılmamıştır. İncelenen yayın sayısının sınırlı olması ve konu odaklı seçimin sistematik derleme protokolüne dayanmaması diğer sınırlılıklardır. Buna rağmen seçilen çalışmalar DÜP, sürdürülebilir talaşlı imalat, karbon modelleme ve yaşam döngüsü değerlendirmesi eksenlerini birlikte kapsamakta pilot uygulama için gerekli asgari veri alanlarının belirlenmesine imkân vermektedir.

SONUÇ

Bu çalışmada Dijital Ürün Pasaportu yaklaşımının talaşlı imalatta karbon izlenebilirliği açısından uygulanabilirliği incelenmiştir. Literatür değerlendirmesi, talaşlı imalatın karbon ayak izinin elektrik tüketiminin ötesinde hammadde, kesici takım, kesme sıvısı, işlem süresi, boşta çalışma ve atık geri kazanımını kapsayan çok kaynaklı bir yapı olduğunu göstermiştir. Bu nedenle ürün pasaportunda yalnızca nihai karbon göstergesinin tutulması yeterli değildir. Sonucu üreten tezgâh, işlem parametreleri, süreler, sarf girdileri, sistem sınırı ve emisyon faktörleri de kaydedilmelidir.

Ürün ve malzeme, işlem, enerji, takım ve kesme sıvısı, atık ve geri kazanım ile karbon göstergelerinden oluşan altı bileşenli çerçeve, bu gereksinimleri ortak bir veri yapısında birleştirmektedir. Çerçeve karbon yoğun operasyonların belirlenmesi, alternatif üretim senaryolarının karşılaştırılması ve geri kazanım kararlarının desteklenmesi için uygulanabilir bir başlangıç sunmaktadır. Gelecek çalışmalarda çerçevenin seçilecek bir parçanın gerçek üretim rotasında pilot olarak uygulanması enerji analizörü, CNC kayıtları ve malzeme akışlarından elde edilen verilerle doğrulanması önerilmektedir. Ayrıca veri alanlarının mevcut DÜP standartlarıyla eşleştirilmesi, erişim yetkilerinin tanımlanması ve farklı karbon hesaplama sınırlarının sonuç üzerindeki etkisinin karşılaştırılması gerekmektedir.

Abstract
Natural fiber reinforced thermoplastic composites (NFRTC) are attracting more attention due to their environmental benefits and potential for improved material properties. NFRTCs present a sustainable alternative to traditional materials using bio-based polymers and natural fibers. That kind of composites generally have lower strength compared to synthetic fiber composites. However, the addition of natural fillers can improve mechanical properties such as tensile and flexural strength, although they may increase moisture absorption due to surface interactions. Improving surface compatibility between the polymer and natural fiber through surface modification is one of the most critical factors, which affects the properties of natural fiber-filled polymeric composites. In this study, two different surface treatment methods were applied to coconut fiber (Coir) to improve the mechanical properties of polylactic acid (PLA)-based composites reinforced with Coir. Coir surfaces were subjected to alkaline and epoxy-functional silane modifications. Coir surfaces were analyzed by FTIR spectroscopy. For composites with 20 wt% Coir content, PLA and Coir samples were compounded by melt-extrusion, followed by an injection molding process. Mechanical performance, melt-flow, water uptake, viscoelastic and morphological behaviors of the composites were characterized using tensile-impact-hardness tests, melt-flow index measurements, water absorption measurements, dynamic mechanical analysis, and scanning electron microscopy, respectively. Discussions of findings were conducted regarding the comparison of surface-treated and untreated fiber involvement in composite samples. According to research results, the enhancements in the performance and reliability of composites by applying surface treatments contribute to the use of PLA/CF composites in various application fields.

Özet
Doğal elyaf takviyeli termoplastik kompozitler (DETTK), çevresel faydaları ve malzeme özelliklerinin iyileştirilmesi potansiyeli nedeniyle giderek daha fazla ilgi çekmektedir. DETTK'ler, biyo-polimerler ve doğal lifler kullanarak geleneksel malzemelere sürdürülebilir bir alternatif sunmaktadır. Bu tür kompozitler, sentetik elyaf kompozitlere kıyasla genellikle daha düşük mukavemete sahiptir. Bununla birlikte, doğal katkı maddelerinin eklenmesi, yüzey etkileşimleri nedeniyle nem emilimini artırabilse de, çekme ve eğilme mukavemeti gibi mekanik özellikleri iyileştirebilir. Polimer ve doğal lif arasındaki yüzey uyumluluğunun yüzey modifikasyonu yoluyla iyileştirilmesi, doğal lif dolgulu polimerik kompozitlerin özelliklerini etkileyen en kritik faktörlerden biridir. Bu çalışmada, hindistan cevizi lifi (HCL) ile takviye edilmiş polilaktik asit (PLA) bazlı kompozitlerin mekanik özelliklerini iyileştirmek için HCL'ye iki farklı yüzey işleme yöntemi uygulanmıştır. HCL yüzeyleri alkali ve epoksi-fonksiyonel silan modifikasyonlarına tabi tutulmuştur. HCL yüzeyleri FTIR spektroskopisi ile analiz edilmiştir. %20 CF içeriğine sahip kompozitler için, PLA ve CF numuneleri eriyik ekstrüzyonu ve ardından enjeksiyon kalıplama işlemi ile birleştirilmiştir. Kompozitlerin mekanik performansı, erime akışı, su emme, viskoelastik ve morfolojik davranışları sırasıyla, çekme-darbe sertliği testleri, erime akışı indeksi ölçümleri, su emme ölçümleri, dinamik mekanik analiz ve taramalı elektron mikroskobu kullanılarak

karakterize edilmiştir. Bulguların tartışılması, kompozit numunelerde yüzey işlem görmüş ve işlem görmemiş liflerin karşılaştırılmasıyla ilgili olarak yapılmıştır. Araştırma sonuçlarına göre, yüzey işlemlerinin uygulanmasıyla kompozitlerin performansında ve güvenilirliğinde sağlanan iyileştirmeler, PLA/CF kompozitlerinin çeşitli uygulama alanlarında kullanımına katkıda bulunmaktadır.

ABSTRACT
This study presents a numerical investigation of a commercial 10×7E propeller. A geometry reconstruction workflow is outlined which enables the generation of a three-dimensional blade model starting from publicly available tabulated manufacturer data. The procedure is intended to be repeatable for researchers studying similar commercial propellers. The reconstruction process involved importing tabulated station data, scaling the section profiles according to their corresponding chord length and thickness ratios, and applying spatial translations within a CAD environment. Steady RANS simulations were used to evaluate the aerodynamic performance of the reconstructed reference propeller. The numerical results reproduced the overall trends of the available UIUC experimental data with good agreement near the condition of maximum propulsive efficiency. To quantitatively validate the reconstructed baseline model, performance was analyzed using thrust coefficient (C_T), power coefficient (C_P), and Froude efficiency at two distinct advance ratios (J = 0.35 and J = 0.62). At the higher advance ratio of J = 0.62, the reconstructed model demonstrated excellent alignment with the UIUC data, predicting a C_T of 0.0397, a C_P of 0.0346, and an efficiency of 0.707 against the UIUC reference values of 0.0400, 0.0350, and 0.701, respectively. At the lower advance ratio of J = 0.35, the numerical model predicted a C_T of 0.0803, a C_P of 0.0502, and an efficiency of 0.564, compared to the UIUC baseline values of 0.0910, 0.0534, and 0.597. These results confirm that standardizing the airfoil coordinate datasets yields a reliable geometric baseline for further aerodynamic evaluations, particularly under high-efficiency operating conditions.
Keywords: Drone, propeller, RANS simulation

1. INTRODUCTION
Small electric propellers operating at low Reynolds numbers serve as the primary propulsion mechanisms for multirotor drones and small unmanned aerial vehicles (UAVs). The aerodynamic performance of these propulsion systems is highly dependent on complex blade geometry, rotational kinematics, and transitional boundary-layer behavior.
The primary objective of this study is to perform a detailed geometric reconstruction of the commercially available APC 10×7E propeller using open-source manufacturer data (APC Propellers, 2026), and to rigorously validate the aerodynamic performance of this baseline model through computational fluid dynamics approaches. By employing steady RANS simulations coupled with advanced transition modeling, this research resolves the boundary-layer behavior and compares the numerical outcomes with established experimental datasets, thereby establishing a reliable methodology for evaluating off-the-shelf propeller aerodynamics.

2. METHODOLOGY

2.1. Blade geometry reconstruction
The propeller selected for this investigation is the APC Thin Electric 10×7E, a widely utilized off-the-shelf rotor designed for electrically driven UAV applications. The propeller features a hub diameter of 0.80 inches, an overall diameter of 10 inches, and a pitch of 7 inches. In the absence of a native CAD file, the blade geometry was reconstructed using tabulated data provided by the manufacturer. This dataset includes chord length, thickness ratio, twist angle, and z-high values distributed across 36 radial stations extending from the hub to the blade tip.

The aerodynamic profile changes along the blade. An Eppler 63 airfoil is used from the root to a 0.73R radial location, while the rest of the blade uses an APC12 section (which the manufacturer declares as equivalent to NACA 4412). Due to the exact APC12 profile not being public, the NACA 4412 model is used instead. However, this creates uncertainty in the shape and aerodynamic results, which is common in commercial propeller studies (Alves, 2014; Jdiobe, Rouser, Paul, & Rouser, 2022; Lowe, 2009). The reconstruction process was initiated by importing the tabulated station data into the XFLR5 (Deperrois, 2013) environment, where each section profile was appropriately scaled. Subsequently, the scaled airfoils were exported to the Siemens NX CAD software. Through precise translation and rotation operations regarding the designated *x*/*c* locations, a lofting procedure was executed to generate the final 3D solid body. Visual inspection against the physical product confirmed an excellent geometric agreement, with only negligible deviations observed near the complex hub to blade transition region.

2.2. Numerical model and simulation details

The aerodynamic performance of the propeller is quantified using standard dimensionless parameters. The advance ratio is defined as

$$J = \frac{V_\infty}{nD}, \tag{1}$$

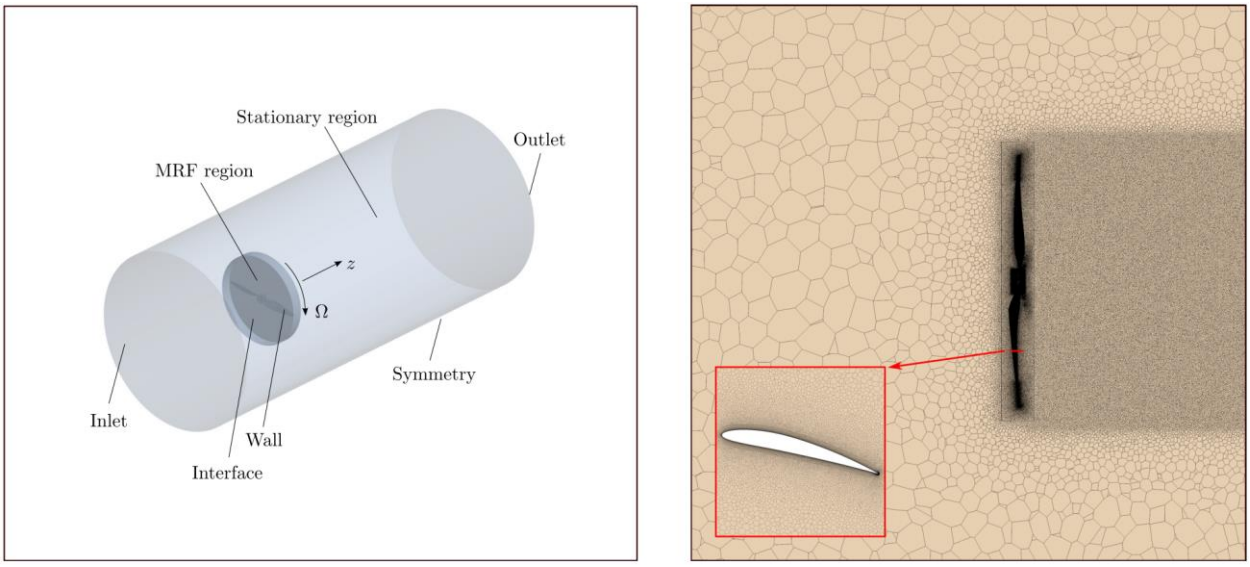
where V_∞ is the free-stream velocity, n is the rotational speed in revolutions per second, and D is the propeller diameter. The thrust and power coefficients are defined as

$$C_T = \frac{T}{\rho n^2 D^4} \text{ and } C_P = \frac{P}{\rho n^3 D^5}, \tag{2}$$

respectively, while the propulsive efficiency is calculated as

$$\eta = \frac{JC_T}{C_P}. \quad (3)$$

A representative Reynolds number is defined at the 0.75R blade section as



$$Re_{0.75} = \frac{\rho V_\infty c}{\mu}, \quad (4)$$

where the local relative velocity $V_{Rel} = \sqrt{V_\infty^2 + (2\pi nr)^2}$ and the local chord c are evaluated at $0.75R$. The dynamic viscosity is denoted by μ.

The computational fluid dynamics analyses were conducted utilizing Siemens Simcenter STAR-CCM+. A steady Moving Reference Frame (MRF) approach was adopted to model the rotational motion, as this method provides reliable predictions of mean thrust and torque at a practical computational cost (Baltazar, Rijpkema, & Falcão de Campos, 2019; Garofano-Soldado, Sanchez-Cuevas, Heredia, & Ollero, 2022; Zhang, Xie, Wang, & An, 2023). The computational domain was constructed as a cylinder with a diameter of $2.2D$, extending $1.5D$ upstream and $3.5D$ downstream from the propeller plane.

To resolve the complex geometric features and ensure accurate gradient calculations, a polyhedral (Jasak, 1996; Wang, Cao, & Okaze, 2021) mesh comprising approximately 9.24×10^6 cells was utilized. Specifically, a 10-layer prism mesh with a total thickness of 0.25 mm and a first-layer height of 0.01 mm was applied to all blade surfaces, maintaining an average dimensionless wall distance of $y^+ \approx 0.64$.

Flow calculations were performed using the finite volume method and the SIMPLE algorithm, a standard method for linking pressure and velocity in incompressible flows (Ferziger, Perić, & Street, 2020). Turbulence was modeled via the Menter SST $k-\omega$, and to accurately account for laminar to turbulent transition phenomena at low Reynolds numbers ($Re_{0.75} \approx 7.2 \times 10^4$), a γ-based transition model was integrated into the solver.

(a) (b)

3. RESULTS AND DISCUSSION

The fidelity of the RANS modeling approach was verified by comparing the predicted aerodynamic coefficients against the APC manufacturer database and independent wind-tunnel measurements from the UIUC. The advance ratio was swept from $J = 0.18$ to $J = 0.85$ while maintaining a constant rotational speed of 6000 RPM.

At the design condition corresponding to maximum propulsive efficiency $J \approx 0.62$, the numerically predicted thrust coefficient, power coefficient, and propulsive efficiency demonstrated excellent alignment with the UIUC experimental measurements. This indicates that the numerical method accurately captures the governing aerodynamic physics when the blade sections are optimally aligned with the incoming flow. At lower advance ratios, a minor deviation between the calculated thrust values and the experimental data was observed. These differences are mainly caused by complex three-dimensional flow effects, such as increased angles of attack and strong secondary flow effects near the hub, which standard steady RANS models struggle to capture under heavily loaded, off-design conditions. Nonetheless, the calculated power coefficient (C_P) successfully captured the plateauing behavior observed in the experimental data at low advance ratios, confirming the overall reliability of the computational setup.

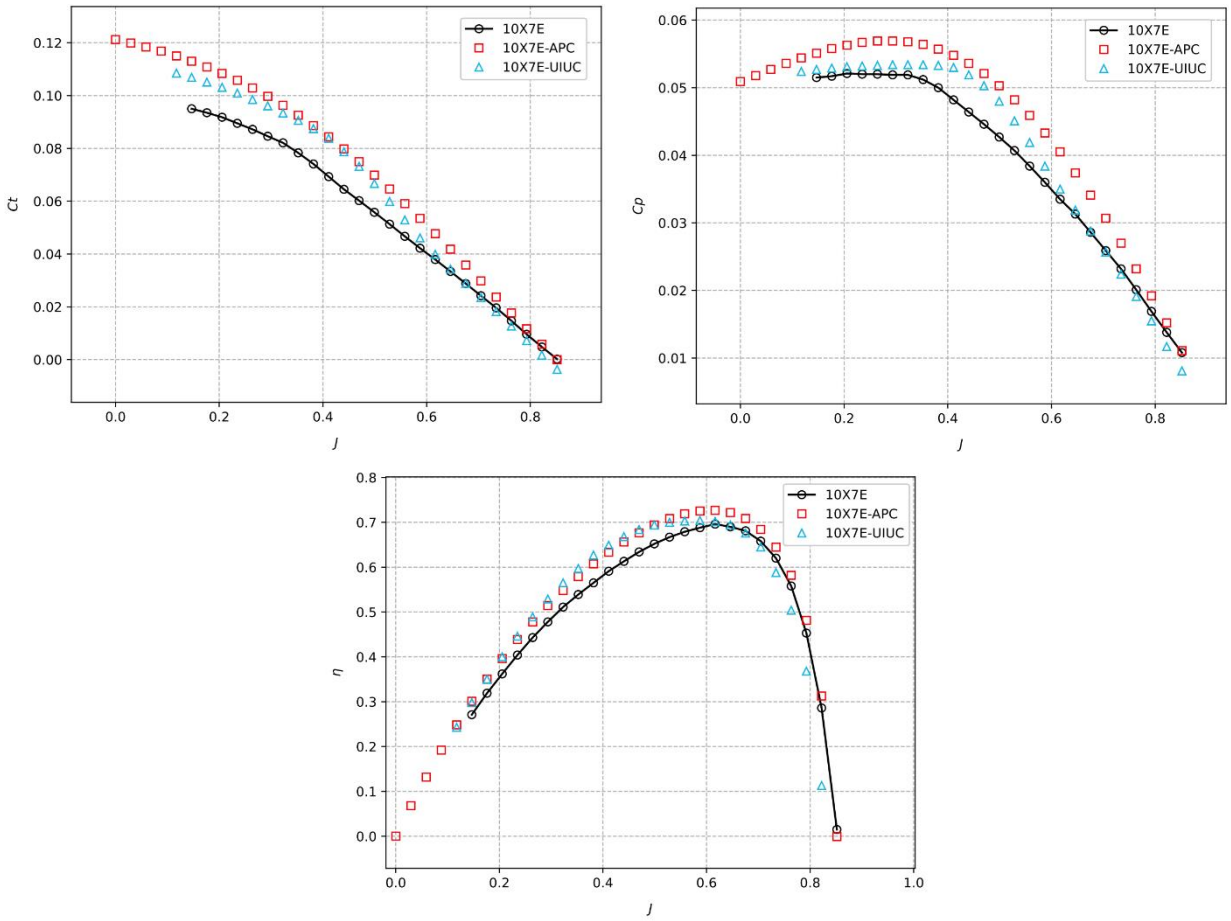

Figure 5 Comparison of propeller performance obtained from RANS simulations (black), UIUC wind-tunnel experiments (blue, Brandt (2008)), and APC database results (red, APC Propellers (2026)) for validation.

4. CONCLUSION

This research demonstrated a robust, repeatable geometry reconstruction workflow for the commercial APC 10×7E drone propeller, utilizing solely publicly available tabulated manufacturer data. This methodology provides a foundation for researchers seeking to perform high-fidelity CFD analyses on commercial propulsion systems lacking native CAD documentation.

The steady RANS computational model predicted the overall aerodynamic behavior of the reconstructed blade. To quantitatively validate the baseline model, performance metrics were evaluated against independent UIUC wind tunnel experimental data (Brandt, 2008; Selig, 2015) at two distinct advance ratios. At the higher advance ratio of J = 0.62, corresponding to peak propulsive efficiency, the numerical model demonstrated excellent alignment, predicting a thrust coefficient (C_T) of 0.0397, a power coefficient (C_P) of 0.0346, and an efficiency (η) of 0.707. These results closely matched the UIUC reference values of 0.0400, 0.0350, and 0.701, respectively. Lower advance ratio of J = 0.35, the model predicted a C_T of 0.0803, a C_P of 0.0502, and an efficiency of 0.564, compared to the UIUC measurements of 0.0910, 0.0534, and 0.597. While minor deviations were observed at this lower advance ratio due to pronounced three-dimensional rotational effects, these quantitative results confirm that standardizing the airfoil coordinate datasets yields a reliable geometric baseline for further aerodynamic evaluations, particularly under high-efficiency operating conditions.

ABSTRACT
The implementation of higher education quality assurance in Indonesia is currently facing a fundamental shift following the enactment of the Regulation of the Minister of Higher Education, Science, and Technology (Permendiktisaintek) Number 39 of 2025. This regulation replaces the previous framework, Permendikbudristek Number 53 of 2023, which aimed at simplifying national standards. This research aims to analyze the legal gaps arising from the rapid transition between these two regulations and the institutional readiness of universities to adapt to the new "Global Quality" orientation. Using a normative-conceptual approach, this study identifies a significant gap between the normative requirement for universities to exceed National Higher Education Standards (SN Dikti) and the empirical reality of administrative and financial constraints, particularly for private higher education institutions. The analysis highlights three main issues: the legal consequences of the two-year transition period, the problematic funding and independence of Independent Accreditation Agencies (LAM), and the challenges of integrating data with the Higher Education Database (PD Dikti). The findings suggest that while the new regulation provides greater flexibility, it requires a robust internal quality culture and a realistic roadmap for digital infrastructure to bridge the gap between compliance and excellence.

ABSTRACT
Underage marriage is not something new in Indonesia. This practice has long been the case with so many actors. Not only in big cities but in the hinterland is also a lot going on. The causes vary due to economic problems, lack of education, cultural understanding and the values of a particular religion and the most common problems is pregnant outside marriage (accident or popular with the term married by accident) and other reasons. Usually marriages under age not given birth family happiness and households, thus many lead to divorce and other impacts.
This study using literature data and the data obtained directly from the community as well as information from relevant agencies. A research technique used is the technique of interviewing on interviewees of Religious Court Samarinda Class IA. Methods of analysis of data from this study, using a qualitative analysis, then presented descriptively. The research objective to be achieved include: (1) To gain an understanding that underage marriage should not happen; (2) To determine and analyze the sanctions against breaches of the underage marriage; (3) To know and analyze the impact of underage marriage, particularly divorce. Research conclusion that: (1) The bad impact of underage marriage is increasing maternal mortality and especially the impact of divorce that rise in Indonesia and Samarinda in particular. (2) The sanctions law imposed on anyone who violates the provisions of the law of marriage and child protection laws. Judging from the law that marriage is legalized by the procedures and requirements of the religion that believed the nature of the marriage is valid.

CRIMINAL LIABILITY OF PUBLIC OFFICIALS IN THE ISSUANCE OF CONSTRUCTION PERMITS IN THE REPUBLIC OF MOLDOVA: ABUSE OF OFFICE, NEGLIGENCE AND THE IMPACT OF ADMINISTRATIVE DECISIONS

VATAMANİTA MARIANA

Dr. in law, "Constantin Stere"University of European Political and Economic Science, Faculty of Law, Department of Law, Republic of Moldova

ABSTRACT

The issuance of construction permits represents an essential administrative function through which public authorities ensure compliance with urban planning, construction, environmental, safety, and property protection requirements. In the Republic of Moldova, the increasing complexity of construction activities and administrative procedures creates significant risks associated with unlawful decision-making, abuse of office, negligence, and insufficient institutional control. This article examines the criminal liability of public officials involved in the issuance of construction permits, with particular emphasis on abuse of office and negligence in office under the Criminal Code of the Republic of Moldova. The research analyses the relationship between administrative unlawfulness and criminal liability, emphasizing that the mere annulment or illegality of an administrative decision does not automatically constitute a criminal offence. Particular attention is given to the provisions of the Urbanism and Construction Code No. 434/2023, which establishes requirements for the issuance of construction permits and defines the responsibilities of public authorities and officials involved in the permitting process. The study examines the legal criteria for distinguishing intentional abuse of office from negligent performance of official duties, including the mental element, the existence of legally relevant damage, and the causal relationship between the official's conduct and the resulting consequences. The research demonstrates that unlawful construction permits may generate significant risks for property rights, public safety, urban development, and environmental protection. The article argues that effective prevention of such offences requires increased administrative transparency, digitalisation of permitting procedures, institutional supervision, professional verification, and clear individualisation of responsibility. A balanced approach is necessary to ensure accountability while preventing the unjustified criminalisation of bona fide administrative decision-making.

Keywords: construction permits, public officials, criminal liability, abuse of office, negligence in office.

INTRODUCTION

Construction activity is closely connected with the public interest because decisions concerning the location, design, construction and use of buildings may directly affect property rights, public safety, environmental protection, urban development and the quality of life of communities. Consequently, the state establishes a system of administrative authorisation intended to prevent unlawful or unsafe construction and to ensure compliance with planning and technical requirements.

In the Republic of Moldova, the legal framework governing construction permits has undergone substantial development. The current regulatory framework is centred on the Urbanism and Construction Code No. 434/2023, which regulates urban planning, construction permitting, the execution and reception of construction works, quality control and state supervision. The Code contains a dedicated title concerning construction and demolition permits and expressly regulates the obligations and responsibilities of issuers (Parliament of the Republic of Moldova, 2023).

The construction permit is not merely a formal administrative document. It constitutes an important legal instrument through which the competent authority verifies whether the proposed construction satisfies statutory requirements. Under Article 148 of the Urbanism and Construction Code, the construction permit is issued within the prescribed procedure and on the basis of specified documentation, including project documentation and, where applicable, environmental, cultural heritage, infrastructure and other approvals. The issuer must refuse the permit where the documentation contains falsified or erroneous information or where the project does not comply with urban planning requirements (Parliament of the Republic of Moldova, 2023).

This regulatory responsibility raises an important question: under what circumstances does an unlawful administrative decision become a criminal offence committed by the public official responsible for issuing, approving or signing the construction permit?

The answer cannot be reduced to the existence of an unlawful permit. Administrative unlawfulness and criminal unlawfulness are related but distinct legal categories. A permit may be annulled by an administrative authority or court without necessarily establishing the criminal liability of the official who issued it. Criminal liability requires the fulfilment of the legal elements of a specific offence.

This distinction is particularly important in relation to Articles 327 and 329 of the Criminal Code of the Republic of Moldova, which regulate abuse of power or abuse of office and negligence in office, respectively (Parliament of the Republic of Moldova, 2002).

This distinction is particularly important in relation to Articles 327 and 329 of the Criminal Code of the Republic of Moldova, which regulate abuse of power or abuse of office and negligence in office, respectively (Parliament of the Republic of Moldova, 2002).

1.1.INDIVIUDAL RESPONSIBILITY OF THE ISSUING OFFICIAL

One of the most important innovations of the current Moldovan construction legislation is the express regulation of the responsibility of persons involved in the issuance of construction permits.

Article 159 of the Urbanism and Construction Code of the Republic of Moldova establishes specific obligations of the issuer. These include the use of SIA GEAP, ensuring that the preparation of the permit takes place without the applicant's involvement, registration and transmission of information concerning issued permits to the central database of the Register of Permissive Acts, as well as ensuring public access to relevant information (Parliament of the Republic of Moldova, 2023).

Article 161 goes further by providing that responsibility for the correctness of the issuance of construction and demolition permits rests jointly with the persons who signed them.

This provision is particularly relevant from the perspective of criminal law because the issuance procedure may involve several officials. The mayor, local council secretary, chief architect or other authorised persons may participate in signing the permit, depending on the category of project and administrative structure. The current Code expressly regulates who signs the permit in different circumstances.

However, joint administrative responsibility should not automatically be equated with joint criminal responsibility.

1. Criminal liability remains personal. Each official must be assessed according to his or her own conduct, competence, knowledge, duties, contribution to the decision-making process and mental attitude toward the violation.
2. Therefore, in criminal proceedings it is necessary to establish:
3. the exact legal and professional duties of the official;
4. whether the official had actual competence in the relevant procedure;
5. which documents were available to the official;
6. whether the violation was objectively detectable;
7. whether the official personally signed, approved, endorsed or otherwise contributed to the unlawful decision;
8. whether the official acted intentionally or negligently;
9. whether legally relevant damage resulted from the conduct; and
10. whether a causal relationship exists between the official's conduct and the damage.

This approach prevents the criminalisation of officials merely because they participated formally in an administrative procedure.

1.2.ABUSE OF OFFICE IN THE ISSUANCE OF CONSTRUCTION

Article 327 of the Criminal Code of the Republic of Moldova regulates abuse of power or abuse of office. The current formulation criminalises intentional performance or non-performance, in the exercise of official duties, of an action in violation of the law, when committed for a material interest, another personal interest or the interest of a third person and resulting in considerable damage to legally protected rights and interests (Parliament of the Republic of Moldova, 2002).

The offence therefore contains several essential components:

a) a public official as the perpetrator;

b) conduct occurring in the exercise of official duties;
c) violation of legal requirements;
d) intentional conduct;
e) a material, personal or third-party interest;
f) legally relevant damage; and
g) causal connection between the unlawful conduct and the damage.

In the context of construction permits, abuse of office may potentially arise where an official knowingly issues a permit despite the absence of mandatory documents, knowingly disregards a statutory prohibition, intentionally approves a project that does not satisfy urban planning requirements, or deliberately facilitates the interests of a particular developer. However, the existence of an unlawful permit alone does not prove abuse of office. The prosecution must establish the official's intentional violation of the law and the legally required interest motivating the conduct.

1.3.TYPICAL FORMS OF ABUSIVE CONDUCT

From a criminal-law perspective, the issuance of construction permits represents an area in which the exercise of public authority may generate significant legal consequences when statutory requirements are deliberately disregarded. Public officials involved in the permitting process are entrusted with the responsibility of verifying whether the proposed construction complies with applicable urban planning, technical, environmental, safety, property, and administrative requirements. Consequently, the intentional misuse of official powers in this field may, depending on the circumstances and the evidence available, fall within the scope of abuse of office as regulated by Article 327 of the Criminal Code of the Republic of Moldova (Parliament of the Republic of Moldova, 2002).

A first hypothetical situation concerns the intentional issuance of a construction permit despite the official's knowledge that mandatory approvals or supporting documents are missing. In the ordinary permitting procedure, the official has a duty to verify whether the application is accompanied by the documentation required by law. If the official is aware that a mandatory approval has not been obtained, but nevertheless deliberately proceeds with the issuance of the permit, the conduct may represent more than a simple administrative error. The criminal-law assessment would depend, in particular, on establishing that the official knew about the missing documentation, possessed the legal competence to refuse or suspend the procedure, and nevertheless intentionally decided to issue the permit. Where the conduct is additionally motivated by a material, personal, or third-party interest and produces the legally required damage, the elements of abuse of office may potentially be established.

A second situation may arise where an official knowingly authorises construction in breach of mandatory urban planning restrictions in order to favour a particular private developer. Urban planning restrictions are designed to protect the public interest and to ensure the coherent development of settlements. They may concern land-use regulations, construction parameters, protected areas, height restrictions, building density, distances from neighbouring properties, infrastructure requirements, or other mandatory planning conditions. If an official is fully aware that a proposed project contradicts binding planning rules but intentionally approves the project because of a relationship with, or an interest in benefiting, a particular developer, the administrative decision may acquire a clear criminal-law dimension. In such circumstances, the investigation would need to establish not only the unlawfulness of the permit but also the official's knowledge of the applicable restrictions, the intentional nature of the decision, the existence of the relevant personal or third-party interest, and the resulting damage.

A third hypothetical situation concerns the deliberate disregard of falsified, incomplete, or manifestly erroneous documents submitted by the applicant. The permitting authority is expected to assess the formal and legal validity of the documentation submitted in support of the application. Where an official is made aware that documents contain false information or significant inconsistencies, but consciously ignores those deficiencies and issues the permit, the official's conduct may potentially constitute an abuse of official powers. This situation is particularly relevant where the false documentation concerns essential aspects of the project, such as ownership rights, land-use conditions, technical parameters, structural characteristics, environmental approvals, or compliance with urban planning documentation. Nevertheless, the mere existence of an incorrect document is insufficient to establish criminal liability. It must be demonstrated that the official knew, or was otherwise consciously aware, of the relevant irregularity and deliberately chose to disregard it.

A fourth situation involves the manipulation of the administrative permitting procedure in order to circumvent statutory requirements or accelerate the issuance of a construction permit for a favoured applicant. Such manipulation may take different forms, including bypassing mandatory procedural stages, improperly reducing verification periods, preventing other competent institutions from providing required opinions, altering the sequence of administrative actions, or deliberately avoiding checks that could reveal deficiencies in the application. From a criminal-law perspective, the essential issue is whether the official intentionally used his or her position and institutional powers to defeat the purpose of the statutory procedure. Where such conduct is directed toward obtaining an unlawful advantage for a particular applicant and causes legally relevant damage, it may warrant investigation under the provisions concerning abuse of office.

A fifth situation may arise where an official knowingly signs or endorses a construction permit despite the existence of a previous administrative or technical finding demonstrating that the proposed project does not satisfy applicable legal or technical requirements. Such circumstances are particularly significant because a prior technical report, inspection finding, administrative refusal, or expert assessment may provide objective evidence that the official was aware of the project's deficiencies. If, despite this information, the official deliberately signs the permit, the evidentiary significance of the prior finding may be considerable in determining the official's knowledge and intent. The investigation should nevertheless establish whether the official had access to the relevant finding, whether it fell within the official's sphere of responsibility, and whether the official had the legal authority to prevent the issuance of the permit.

These hypothetical situations demonstrate that the criminal-law assessment of unlawful construction permits cannot be based exclusively on the final administrative outcome. The fact that a construction permit is subsequently annulled, declared unlawful, or found to have been issued contrary to urban planning legislation does not, by itself, establish the criminal liability of the official who participated in its issuance. Criminal liability requires an individualised examination of the conduct of each person involved in the administrative process.

Particular importance must therefore be attributed to the subjective element of the offence. In cases involving abuse of office, investigators must establish whether the official acted intentionally and whether the conduct was associated with the material, personal, or third-party interest required by the criminal-law provision. This requires an examination of the circumstances existing at the moment the administrative decision was adopted, rather than relying solely on the harmful consequences that subsequently occurred.

Evidence may include the content of the administrative file, internal correspondence, electronic records, entries in digital permitting systems, technical opinions, inspection reports, communications between officials and applicants, financial information, and other circumstances capable of demonstrating the official's knowledge and purpose. The digitalisation of construction-permitting procedures may be particularly important because electronic records can make it possible to reconstruct the chronology of the decision-making process and identify the persons who prepared, verified, approved, modified, or signed relevant documents.

Accordingly, the criminal investigation should distinguish between an objective violation of construction legislation and an intentional misuse of official authority. The first may justify administrative, disciplinary, or contraventional consequences, whereas the second, when accompanied by all legally required elements, may give rise to criminal liability.

The central principle should therefore be that an unlawful construction permit is not automatically equivalent to abuse of office. Criminal responsibility can arise only where the prosecution establishes, beyond the mere existence of an administrative irregularity, the specific conduct of the official, the violation of the applicable legal duty, the required mental element, the legally relevant interest or purpose, the existence of legally significant damage, and the causal relationship between the official's conduct and the resulting consequences. This approach ensures both effective protection of the public interest and respect for the principle of legality and the individualisation of criminal responsibility.

1.4.INDIVIDUAL RESPONSIBILITY OF THE ISSUING OFFICIAL

One of the most important innovations of the current Moldovan construction legislation is the express regulation of the responsibility of persons involved in the issuance of construction permits.

Article 159 of the Urbanism and Construction Code establishes specific obligations of the issuer. These include the use of SIA GEAP, ensuring that the preparation of the permit takes place without the applicant's involvement, registration and transmission of information concerning issued permits to the central database of the Register of Permissive Acts, as well as ensuring public access to relevant information (Parliament of the Republic of Moldova, 2023).

Article 161 goes further by providing that responsibility for the correctness of the issuance of construction and demolition permits rests jointly with the persons who signed them.

This provision is particularly relevant from the perspective of criminal law because the issuance procedure may involve several officials. The mayor, local council secretary, chief architect or other authorised persons may participate in signing the permit, depending on the category of project and administrative structure. The current Code expressly regulates who signs the permit in different circumstances.

However, joint administrative responsibility should not automatically be equated with joint criminal responsibility.

Criminal liability remains personal. Each official must be assessed according to his or her own conduct, competence, knowledge, duties, contribution to the decision-making process and mental attitude toward the violation.

Therefore, in criminal proceedings it is necessary to establish:

1. the exact legal and professional duties of the official;
2. whether the official had actual competence in the relevant procedure;
3. which documents were available to the official;
4. whether the violation was objectively detectable;
5. whether the official personally signed, approved, endorsed or otherwise contributed to the unlawful decision;
6. whether the official acted intentionally or negligently;
7. whether legally relevant damage resulted from the conduct; and
8. whether a causal relationship exists between the official's conduct and the damage.

This approach prevents the criminalisation of officials merely because they participated formally in an administrative procedure.

1.5.ABUSE OF OFFICE IN THE ISSUANCE OF CONSTRUCTION PERMITS

Article 327 of the Criminal Code of the Republic of Moldova regulates abuse of power or abuse of office. The current formulation criminalises intentional performance or non-performance, in the exercise of official duties, of an action in violation of the law, when committed for a material interest, another personal interest or the interest of a third person and resulting in considerable damage to legally protected rights and interests (Parliament of the Republic of Moldova, 2002).

The offence therefore contains several essential components:

1. a public official as the perpetrator;
2. conduct occurring in the exercise of official duties;
3. violation of legal requirements;
4. intentional conduct;
5. a material, personal or third-party interest;
6. legally relevant damage; and
7. causal connection between the unlawful conduct and the damage.

In the context of construction permits, abuse of office may potentially arise where an official knowingly issues a permit despite the absence of mandatory documents, knowingly disregards a statutory prohibition, intentionally approves a project that does not satisfy urban planning requirements, or deliberately facilitates the interests of a particular developer.

However, the existence of an unlawful permit alone does not prove abuse of office. The prosecution must establish the official's intentional violation of the law and the legally required interest motivating the conduct.

From a criminal-law perspective, several hypothetical situations may illustrate the potential application of Article 327.

First, an official may intentionally issue a construction permit despite knowing that the project documentation lacks mandatory approvals.

Second, an official may knowingly approve construction in violation of binding urban planning restrictions in order to benefit a particular private developer.
Third, an official may intentionally ignore falsified or manifestly erroneous documents submitted by the applicant.
Fourth, an official may manipulate the administrative procedure in order to circumvent statutory requirements and accelerate the issuance of a permit for a favoured applicant.
Fifth, an official may knowingly sign a permit despite a prior administrative or technical finding that the proposed project does not comply with applicable requirements.
In each situation, however, criminal liability depends upon evidence establishing the specific elements of the offence.
The second major form of potential criminal liability is negligence in office.
Article 329 of the Criminal Code of the Republic of Moldova provides liability for failure to perform or improper performance by a public official of statutory official duties resulting from a negligent or unconscientious attitude, where this causes damage of a legally significant degree to protected rights and interests. The aggravated forms concern, among other circumstances, persons holding public dignity positions or particularly serious damage (Parliament of the Republic of Moldova, 2002).
The fundamental distinction between Article 327 and Article 329 is therefore the mental element.
Abuse of office requires intentional conduct combined with the legally specified interest. Negligence, by contrast, concerns improper performance or failure to perform official duties resulting from a negligent or unconscientious attitude.
This distinction is particularly important in the construction sector because permitting procedures frequently involve highly technical documentation.
An official may be confronted with architectural plans, structural calculations, environmental assessments, technical reports, property documents and multiple administrative approvals. The official cannot necessarily be expected to possess the specialised knowledge of an architect, engineer or technical expert.
Consequently, criminal negligence should not be established merely because a technical defect existed in the documentation.
The investigation must determine whether the official had a legal duty to identify the defect, whether the defect was reasonably identifiable within the official's competence and whether the failure to act represented a legally relevant departure from the standard expected from the official.

1.6.DISTINGUISHING ABUSE FROM NEGLIGENCE

The distinction between abuse of office and negligence in office is of particular importance when examining the criminal liability of public officials involved in the issuance of construction permits in the Republic of Moldova. Although both offences may involve a violation or improper performance of official duties and may produce legally significant damage, they differ fundamentally with regard to the mental element, the nature of the official's conduct, and the evidentiary requirements necessary to establish criminal responsibility.
The most important distinction concerns the mental element. Abuse of office presupposes intentional conduct. The official consciously performs an action or deliberately fails to perform an action that falls within his or her official duties, while being aware of the unlawfulness of that conduct. In contrast, negligence in office is characterised by a negligent or unconscientious attitude toward the performance of official duties. The official does not necessarily intend the harmful consequence or the violation itself but fails to exercise the degree of care, attention, and diligence required by the position.
This distinction becomes particularly relevant in construction permitting procedures, which frequently involve complex technical and legal documentation. An official who knowingly issues a construction permit despite being aware that mandatory requirements have not been fulfilled may potentially act intentionally. By contrast, an official who fails to identify an irregularity because the documentation was not adequately examined, although the official was under a legal duty to conduct such verification, may potentially fall within the sphere of negligence, provided that all statutory elements of the offence are established.
A second important distinction concerns the nature of the conduct. Abuse of office involves the deliberate misuse of the powers or responsibilities associated with public office. The official may use a legally conferred authority for an unlawful purpose or deliberately refrain from exercising that authority

in order to facilitate a particular outcome. In the construction sector, this could include knowingly authorising a project that does not comply with mandatory urban planning requirements, deliberately disregarding an obvious legal prohibition, or intentionally circumventing a prescribed verification procedure.

Negligence in office, by comparison, generally results from the inadequate performance or non-performance of official duties rather than from a deliberate attempt to misuse public authority. For example, an official may fail to verify whether all mandatory documents have been submitted, overlook a significant inconsistency in the administrative file, or improperly perform a verification procedure. The critical question is whether such conduct reflects a legally relevant failure of diligence rather than an intentional decision to violate the law.

Another important criterion is the existence of a material, personal, or third-party interest. In the case of abuse of office under Article 327 of the Criminal Code of the Republic of Moldova, the relevant statutory conditions concerning the interest motivating the conduct must be established. This element is particularly significant where an official deliberately facilitates the interests of a private developer, construction company, intermediary, relative, associate, or another beneficiary. Evidence concerning financial relationships, communications, conflicts of interest, previous interactions, or other circumstances may therefore become relevant to determining the purpose behind the official's conduct.

In negligence cases, such a personal or third-party interest is not the defining feature of the offence. The central issue is instead whether the official failed to perform his or her duties with the level of diligence required by law and whether this failure resulted in the legally relevant consequences prescribed by the criminal law.

The knowledge of the legal violation is also an important evidentiary criterion. In cases involving intentional abuse, the prosecution must demonstrate that the official was aware of the relevant circumstances and nevertheless acted contrary to the applicable legal requirements. Evidence may include previous administrative decisions, technical reports, official correspondence, written warnings, internal opinions, inspection findings, or electronic records demonstrating that the official had access to information concerning the irregularity.

In negligence cases, the absence of deliberate knowledge or purpose does not necessarily exclude criminal liability. The investigation must instead determine whether the official should and could reasonably have identified the relevant problem while performing his or her duties. This requires an assessment of the official's legal responsibilities, professional competence, access to information, the complexity of the documentation, the foreseeability of the consequences, and the existence of a causal relationship between the failure to exercise due diligence and the resulting damage.

The typical examples also illustrate the distinction. Knowingly issuing a construction permit for an unauthorised or non-compliant project in order to benefit a particular developer may potentially indicate abuse of office. Conversely, issuing a permit without properly examining mandatory documentation, where the official's failure results from inadequate diligence rather than an intention to favour the applicant, may potentially raise the issue of negligence in office.

The evidentiary focus consequently differs between the two forms of liability. In abuse-of-office cases, particular attention must be given to proving intentional conduct and the legally relevant interest or purpose behind the official's actions. In negligence cases, the investigation must concentrate on the scope of the official's duties, the applicable standard of professional diligence, the foreseeability of the harmful consequences, and the causal connection between the omission or improper performance and the resulting damage.

The distinction is therefore not merely theoretical. An incorrect legal classification may have significant consequences for both the individual official and the effectiveness of criminal justice. Treating every unlawful administrative decision as intentional abuse of office could lead to the unjustified criminalisation of administrative errors, professional disagreements, or bona fide decisions made within the scope of legitimate administrative discretion. Conversely, classifying deliberate and motivated misuse of public authority merely as negligence could result in the failure to adequately recognise and prosecute intentional corruption-related or abusive conduct.

This distinction is particularly important in the construction sector because an administrative decision may subsequently be shown to have serious consequences. The annulment of a construction permit, the discovery of an illegal construction, the occurrence of damage to neighbouring property, or the identification of technical deficiencies does not, by itself, establish the mental element of the official

who issued the permit. The criminal investigation must reconstruct the circumstances existing at the time the decision was made and determine what the official knew, what the official was legally required to do, what information was available, and why the official acted or failed to act in a particular manner. The principle of legality and the principle of individualisation of criminal responsibility therefore require a precise assessment of the mental element. The same administrative consequence—such as the issuance of an unlawful construction permit may result from fundamentally different forms of conduct. One official may intentionally disregard the law for the benefit of a private party, while another may make a serious mistake because of inadequate verification, lack of diligence, or failure to properly assess the documentation.

Accordingly, criminal-law analysis should not begin and end with the question of whether the construction permit was lawful. It should additionally determine how and why the unlawful decision was adopted. Only by establishing the subjective attitude of the official, together with the objective elements of the offence, the legally relevant damage, and the causal relationship between the conduct and the consequences, can a correct distinction be made between abuse of office and negligence in office.

This approach ensures an appropriate balance between two competing objectives: effective protection of the public interest against intentional misuse of administrative power and protection of public officials against unjustified criminalisation of bona fide administrative mistakes. Such a balance is particularly important for the Republic of Moldova, where the effectiveness of the construction permitting system depends not only on clear statutory requirements but also on transparent administrative procedures, professional decision-making, institutional supervision, and clearly individualised responsibility.

1.7. THE IMPACT OF ADMINISTRATIVE DECISIONS ON CRIMINAL LIABILITY

An administrative decision may have consequences extending far beyond the immediate applicant.

An unlawfully issued construction permit may enable:

1. construction in violation of an urban development plan;
2. illegal occupation or use of land;
3. infringement of neighbouring property rights;
4. construction in protected areas;
5. environmental damage;
6. deterioration of cultural heritage;
7. creation of risks to public safety;
8. construction of technically unsafe structures; or
9. substantial economic damage to individuals or public authorities.

The Urbanism and Construction Code expressly provides that a permit issued without compliance with urban planning or other statutory requirements may be annulled by the issuer or by a court. It also provides that a person within a local public authority who unlawfully provides the technical or legal basis for issuing a construction permit, or who countersigns or approves the relevant documents, may incur administrative or criminal liability, as appropriate (Parliament of the Republic of Moldova, 2023). This provision creates an important bridge between administrative and criminal law.

The administrative annulment of a permit may constitute significant evidence of unlawfulness, but it should not be treated as automatic proof of a criminal offence. The criminal investigation must independently establish the elements of the relevant offence.

1.6.ADMINISTRATIVED DISCRETION AND LIMITS OF CRIMINALISATION

A particularly difficult issue concerns administrative discretion.

Public officials may have a certain degree of discretion when assessing applications, especially where technical, urban planning or public-interest considerations are involved.

Criminal law should not become an instrument for punishing every administrative decision subsequently considered incorrect.

A distinction must therefore be made between:

a) a legitimate administrative interpretation;
b) an administrative error;
c) an unlawful administrative decision;
d) disciplinary misconduct;

e) administrative or contraventional liability; and
f) criminal conduct.

The existence of disagreement concerning the interpretation of a technical rule does not automatically demonstrate criminal negligence.

Similarly, the subsequent annulment of a construction permit does not by itself prove that the official committed abuse of office.

Criminal law should intervene only where the conduct reaches the threshold established by the Criminal Code.

This approach is especially important because public officials who fear criminal prosecution for every controversial decision may adopt excessively defensive administrative practices, resulting in unnecessary delays and bureaucratisation.

The objective should therefore be accountability without criminalisation of bona fide administrative decision-making.

DISCUSSION AND CONCLUSION

The Moldovan regulatory framework demonstrates a progressive tendency toward individualisation of responsibility in the construction permitting process.

The current Urbanism and Construction Code does not merely establish the applicant's obligations. It also identifies the responsibilities of the issuing authority and the persons who sign construction permits. Article 161 expressly attributes responsibility for the correctness of issued permits to the persons who signed them (Parliament of the Republic of Moldova, 2023).

This approach is important because illegal construction is frequently the result of a chain of decisions rather than a single isolated act.

The applicant may provide incorrect information; the designer may prepare defective documentation; the technical verifier may fail to identify deficiencies; the administrative official may approve the documentation; and another official may sign the final permit.

Consequently, criminal investigation must reconstruct the entire decision-making chain.

The concept of individualised responsibility within a collective administrative process should therefore become a central methodological principle in investigating construction-related offences.

The criminal liability of public officials involved in issuing construction permits represents a particularly important component of the fight against illegal construction and administrative corruption in the Republic of Moldova.

The current Urbanism and Construction Code establishes detailed conditions for issuing construction permits and expressly regulates the responsibilities of issuing authorities and officials. Article 148 imposes specific requirements concerning documentation, verification and compliance with urban planning rules, while Article 161 establishes responsibility for the correctness of permits among the persons who sign them (Parliament of the Republic of Moldova, 2023).

From a criminal-law perspective, the principal distinction must be made between abuse of office under Article 327 and negligence in office under Article 329 of the Criminal Code of the Republic of Moldova (Parliament of the Republic of Moldova, 2002).

Abuse requires intentional unlawful conduct committed for the legally specified interest, whereas negligence concerns failure or improper performance of official duties resulting from a negligent or unconscientious attitude.

The mere unlawfulness or subsequent annulment of a construction permit cannot automatically establish criminal liability. Criminal responsibility requires proof of all elements of the relevant offence, including the mental element, legally significant damage and causation.

For this reason, the investigation of unlawful construction permits should combine legal, administrative, technical, financial and digital evidence.

The study also demonstrates that prevention is as important as repression. Digital permitting systems, transparency, institutional separation of functions, professional training and systematic internal verification can significantly reduce opportunities for abuse and negligence.

Ultimately, the objective of criminal law should not be to punish every administrative error. Its function should be to intervene where an official deliberately transforms public authority into a means of obtaining an unlawful benefit or where a sufficiently serious departure from official duties causes legally relevant harm.

A balanced system of accountability must therefore combine administrative legality, institutional transparency, professional responsibility and proportionate criminal liability. Such an approach is essential for protecting public interests, strengthening confidence in public administration and ensuring lawful and sustainable development of the construction sector in the Republic of Moldova.
